| <code>steps</code>     | the maximum number of steps to be considered. The default is 1000 (essentially as many as required). It is typically used to stop the process early.   |
| <code>k</code>         | the multiple of the number of degrees of freedom used for the penalty. Only $k = 2$ gives the genuine AIC: $k = \log(n)$ is sometimes referred to as BIC or SBC.   |
| <code>...</code>       | any additional arguments to <code>extractAIC</code> .  |

## Details

`step` uses `add1` and `drop1` repeatedly; it will work for any method for which they work, and that is determined by having a valid method for `extractAIC`. When the additive constant can be chosen so that AIC is equal to Mallows'  $C_p$ , this is done and the tables are labelled appropriately.

The set of models searched is determined by the `scope` argument. The right-hand-side of its `lower` component is always included in the model, and right-hand-side of the model is included in the `upper` component. If `scope` is a single formula, it specifies the `upper` component, and the `lower` model is empty. If `scope` is missing, the initial model is used as the `upper` model.

Models specified by `scope` can be templates to update `object` as used by `update.formula`. So using `.` in a `scope` formula means 'what is already there', with `.^2` indicating all interactions of existing terms.

There is a potential problem in using `glm` fits with a variable `scale`, as in that case the deviance is not simply related to the maximized log-likelihood. The "glm" method for function `extractAIC` makes the appropriate adjustment for a gaussian family, but may need to be amended for other cases. (The `binomial` and `poisson` families have fixed `scale` by default and do not correspond to a particular maximum-likelihood problem for variable `scale`.)

## Value

the stepwise-selected model is returned, with up to two additional components. There is an "anova" component corresponding to the steps taken in the search, as well as a "keep" component if the `keep=` argument was supplied in the call. The "Resid. Dev" column of the analysis of deviance table refers to a constant minus twice the maximized log likelihood: it will be a deviance

only in cases where a saturated model is well-defined (thus excluding `lm`, `aov` and `survreg` fits, for example).

### Warning

The model fitting must apply the models to the same dataset. This may be a problem if there are missing values and R's default of `na.action = na.omit` is used. We suggest you remove the missing values first.

Calls to the function `nobs` are used to check that the number of observations involved in the fitting process remains unchanged.

### Note

This function differs considerably from the function in S, which uses a number of approximations and does not in general compute the correct AIC.

This is a minimal implementation. Use `stepAIC` in package **MASS** for a wider range of object classes.

### Author(s)

B. D. Ripley: `step` is a slightly simplified version of `stepAIC` in package **MASS** (Venables & Ripley, 2002 and earlier editions).

The idea of a `step` function follows that described in Hastie & Pregibon (1992); but the implementation in R is more general.

### Examples

```
## following on from example(lm)

step(lm.D9)

summary(lm1 <- lm(Fertility ~ ., data = swiss))
slm1 <- step(lm1)
summary(slm1)
slm1$anova
```

**Description**

Given the vectors  $(x_1, \dots, x_n)$  and  $(y_0, y_1, \dots, y_n)$  (one value more!), `stepfun(x, y, ...)` returns an interpolating ‘step’ function, say `fn`. I.e.,  $fn(t) = c_i$  (constant) for  $t \in (x_i, x_{i+1})$  and at the abscissa values, if (by default) `right = FALSE`,  $fn(x_i) = y_i$  and for `right = TRUE`,  $fn(x_i) = y_{i-1}$ , for  $i = 1, \dots, n$ .

The value of the constant  $c_i$  above depends on the ‘continuity’ parameter `f`. For the default, `right = FALSE`, `f = 0`, `fn` is a *cadlag* function, i.e., continuous from the right, limits from the left, so that the function is piecewise constant on intervals that include their *left* endpoint. In general,  $c_i$  is interpolated in between the neighbouring  $y$  values,  $c_i = (1 - f)y_i + f \cdot y_{i+1}$ . Therefore, for non-0 values of `f`, `fn` may no longer be a proper step function, since it can be discontinuous from both sides, unless `right = TRUE`, `f = 1` which is left-continuous (i.e., constant pieces contain their right endpoint).

**Usage**

```
stepfun(x, y, f = as.numeric(right), ties = "ordered",
        right = FALSE)

is.stepfun(x)
knots(Fn, ...)
as.stepfun(x, ...)

## S3 method for class 'stepfun'
print(x, digits = getOption("digits") - 2, ...)

## S3 method for class 'stepfun'
summary(object, ...)
```

**Arguments**

|                         |   |
|-------------------------|---|
| <code>x</code>          | numeric vector giving the knots or jump locations of the step function for <code>stepfun()</code> . For the other functions, <code>x</code> is as object below. |
| <code>y</code>          | numeric vector one longer than <code>x</code> , giving the heights of the function values <i>between</i> the <code>x</code> values.                             |
| <code>f</code>          | a number between 0 and 1, indicating how interpolation outside the given <code>x</code> values should happen. See <a href="#">approxfun</a> .                   |
| <code>ties</code>       | Handling of tied <code>x</code> values. Either a function or the string "ordered". See <a href="#">approxfun</a> .  |
| <code>right</code>      | logical, indicating if the intervals should be closed on the right (and open on the left) or vice versa.  |
| <code>Fn, object</code> | an R object inheriting from "stepfun".  |
| <code>digits</code>     | number of significant digits to use, see <a href="#">print</a> .  |
| <code>...</code>        | potentially further arguments (required by the generic).  |

**Value**

A function of class "stepfun", say `fn`.

There are methods available for summarizing (`"summary(.)"`), representing (`"print(.)"`) and plotting (`"plot(.)"`, see `plot.stepfun`) "stepfun" objects.

The `environment` of `fn` contains all the information needed;

|                                |  |
|--------------------------------|--|
| <code>"x", "y"</code>          | the original arguments                                   |
| <code>"n"</code>               | number of knots (x values)                               |
| <code>"f"</code>               | continuity parameter                                     |
| <code>"yleft", "yright"</code> | the function values <i>outside</i> the knots             |
| <code>"method"</code>          | (always == "constant", from <code>approxfun(.)</code> ). |

The knots are also available via `knots(fn)`.

**Note**

The objects of class "stepfun" are not intended to be used for permanent storage and may change structure between versions of R (and did at R 3.0.0). They can usually be re-created by

```
eval(attr(old_obj, "call"), environment(old_obj))
```

since the data used is stored as part of the object's environment.

Martin Maechler, <maechler@stat.math.ethz.ch> with some basic code from Thomas Lumley.

**See Also**

`ecdf` for empirical distribution functions as special step functions and `plot.stepfun` for *plotting* step functions.

`approxfun` and `splinefun`.

**Examples**

```
y0 <- c(1., 2., 4., 3.)
sfun0 <- stepfun(1:3, y0, f = 0)
sfun.2 <- stepfun(1:3, y0, f = 0.2)
sfun1 <- stepfun(1:3, y0, f = 1)
sfun1c <- stepfun(1:3, y0, right = TRUE) # hence f=1
sfun0
summary(sfun0)
summary(sfun.2)

## look at the internal structure:
unclass(sfun0)
ls(envir = environment(sfun0))

x0 <- seq(0.5, 3.5, by = 0.25)
rbind(x = x0, f.f0 = sfun0(x0), f.f02 = sfun.2(x0),
      f.f1 = sfun1(x0), f.f1c = sfun1c(x0))
```

```
## Identities :
stopifnot(identical(y0[-1], sfun0 (1:3)), # right = FALSE
           identical(y0[-4], sfun1c(1:3))) # right = TRUE
```

stl

---

Seasonal Decomposition of Time Series by Loess

---

## Description

Decompose a time series into seasonal, trend and irregular components using `loess`, acronym STL.

## Usage

```
stl(x, s.window, s.degree = 0,
    t.window = NULL, t.degree = 1,
    l.window = nextodd(period), l.degree = t.degree,
    s.jump = ceiling(s.window/10),
    t.jump = ceiling(t.window/10),
    l.jump = ceiling(l.window/10),
    robust = FALSE,
    inner = if(robust) 1 else 2,
    outer = if(robust) 15 else 0,
    na.action = na.fail)
```

## Arguments

|                                     |  |
|-------------------------------------|--|
| <code>x</code>                      | univariate time series to be decomposed. This should be an object of class "ts" with a frequency greater than one.   |
| <code>s.window</code>               | either the character string "periodic" or the span (in lags) of the loess window for seasonal extraction, which should be odd and at least 7, according to Cleveland et al. This has no default.   |
| <code>s.degree</code>               | degree of locally-fitted polynomial in seasonal extraction. Should be zero or one.   |
| <code>t.window</code>               | the span (in lags) of the loess window for trend extraction, which should be odd. If NULL, the default, <code>nextodd(ceiling((1.5*period)/(1-(1.5/s.window))))</code> , is taken.   |
| <code>t.degree</code>               | degree of locally-fitted polynomial in trend extraction. Should be zero or one.  |
| <code>l.window</code>               | the span (in lags) of the loess window of the low-pass filter used for each subseries. Defaults to the smallest odd integer greater than or equal to <code>frequency(x)</code> which is recommended since it prevents competition between the trend and seasonal components. If not an odd integer its given value is increased to the next odd one. |
| <code>l.degree</code>               | degree of locally-fitted polynomial for the subseries low-pass filter. Must be 0 or 1.   |
| <code>s.jump, t.jump, l.jump</code> | integers at least one to increase speed of the respective smoother. Linear interpolation happens between every <code>*.jump</code> -th value.  |
| <code>robust</code>                 | logical indicating if robust fitting be used in the <code>loess</code> procedure.  |

|                        |   |
|------------------------|---|
| <code>inner</code>     | integer; the number of ‘inner’ (backfitting) iterations; usually very few (2) iterations suffice. |
| <code>outer</code>     | integer; the number of ‘outer’ robustness iterations.   |
| <code>na.action</code> | action on missing values.   |

### Details

The seasonal component is found by *loess* smoothing the seasonal sub-series (the series of all January values, ...); if `s.window = "periodic"` smoothing is effectively replaced by taking the mean. The seasonal values are removed, and the remainder smoothed to find the trend. The overall level is removed from the seasonal component and added to the trend component. This process is iterated a few times. The `remainder` component is the residuals from the seasonal plus trend fit.

Several methods for the resulting class "`stl`" objects, see, [plot.stl](#).

### Value

`stl` returns an object of class "`stl`" with components

|                          |   |
|--------------------------|---|
| <code>time.series</code> | a multiple time series with columns <code>seasonal</code> , <code>trend</code> and <code>remainder</code> .                     |
| <code>weights</code>     | the final robust weights (all one if fitting is not done robustly).   |
| <code>call</code>        | the matched call.   |
| <code>win</code>         | integer (length 3 vector) with the spans used for the " <code>s</code> ", " <code>t</code> ", and " <code>l</code> " smoothers. |
| <code>deg</code>         | integer (length 3) vector with the polynomial degrees for these smoothers.  |
| <code>jump</code>        | integer (length 3) vector with the ‘jumps’ (skips) used for these smoothers.  |
| <code>ni</code>          | number of <b>inner</b> iterations   |
| <code>no</code>          | number of <b>outer</b> robustness iterations  |

stlmethods

---

*Methods for STL Objects*

---

## Description

Methods for objects of class `stl`, typically the result of `stl`. The `plot` method does a multiple figure plot with some flexibility.

There are also (non-visible) `print` and `summary` methods.

## Usage

```
## S3 method for class 'stl'
plot(x, labels = colnames(X),
      set.pars = list(mar = c(0, 6, 0, 6), oma = c(6, 0, 4, 0),
                      tck = -0.01, mfrow = c(nplot, 1)),
      main = NULL, range.bars = TRUE, ...,
      col.range = "light gray")
```

## Arguments

|                         |  |
|-------------------------|--|
| <code>x</code>          | <code>stl</code> object.   |
| <code>labels</code>     | character of length 4 giving the names of the component time-series.   |
| <code>set.pars</code>   | settings for <code>par(.)</code> when setting up the plot.   |
| <code>main</code>       | plot main title.   |
| <code>range.bars</code> | logical indicating if each plot should have a bar at its right side which are of equal heights in user coordinates.      |
| <code>...</code>        | further arguments passed to or from other methods.   |
| <code>col.range</code>  | colour to be used for the range bars, if plotted. Note this appears after <code>...</code> and so cannot be abbreviated. |

## See Also

`plot.ts` and `stl`, particularly for examples.

StructTS

*Fit Structural Time Series***Description**

Fit a structural model for a time series by maximum likelihood.

**Usage**

```
StructTS(x, type = c("level", "trend", "BSM"), init = NULL,
         fixed = NULL, optim.control = NULL)
```

**Arguments**

`x` a univariate numeric time series. Missing values are allowed.

`type` the class of structural model. If omitted, a BSM is used for a time series with frequency(`x`) > 1, and a local trend model otherwise. Can be abbreviated.

`init` initial values of the variance parameters.

`fixed` optional numeric vector of the same length as the total number of parameters. If supplied, only NA entries in `fixed` will be varied. Probably most useful for setting variances to zero.

`optim.control` List of control parameters for `optim`. Method "L-BFGS-B" is used.

**Details**

*Structural time series* models are (linear Gaussian) state-space models for (univariate) time series based on a decomposition of the series into a number of components. They are specified by a set of error variances, some of which may be zero.

The simplest model is the *local level* model specified by `type = "level"`. This has an underlying level  $\mu_t$  which evolves by

$$\mu_{t+1} = \mu_t + \xi_t, \quad \xi_t \sim N(0, \sigma_\xi^2)$$

The observations are

$$x_t = \mu_t + \epsilon_t, \quad \epsilon_t \sim N(0, \sigma_\epsilon^2)$$

There are two parameters,  $\sigma_\xi^2$  and  $\sigma_\epsilon^2$ . It is an ARIMA(0,1,1) model, but with restrictions on the parameter set.

The *local linear trend model*, `type = "trend"`, has the same measurement equation, but with a time-varying slope in the dynamics for  $\mu_t$ , given by

$$\mu_{t+1} = \mu_t + \nu_t + \xi_t, \quad \xi_t \sim N(0, \sigma_\xi^2)$$

$$\nu_{t+1} = \nu_t + \zeta_t, \quad \zeta_t \sim N(0, \sigma_\zeta^2)$$

with three variance parameters. It is not uncommon to find  $\sigma_\zeta^2 = 0$  (which reduces to the local level model) or  $\sigma_\xi^2 = 0$ , which ensures a smooth trend. This is a restricted ARIMA(0,2,2) model.

The *basic structural model*, `type = "BSM"`, is a local trend model with an additional seasonal component. Thus the measurement equation is

$$x_t = \mu_t + \gamma_t + \epsilon_t, \quad \epsilon_t \sim N(0, \sigma_\epsilon^2)$$

where  $\gamma_t$  is a seasonal component with dynamics

$$\gamma_{t+1} = -\gamma_t + \dots + \gamma_{t-s+2} + \omega_t, \quad \omega_t \sim N(0, \sigma_\omega^2)$$

The boundary case  $\sigma_\omega^2 = 0$  corresponds to a deterministic (but arbitrary) seasonal pattern. (This is sometimes known as the ‘dummy variable’ version of the BSM.)

### Value

A list of class "StructTS" with components:

|                            |   |
|----------------------------|---|
| <code>coef</code>          | the estimated variances of the components.  |
| <code>loglik</code>        | the maximized log-likelihood. Note that as all these models are non-stationary this includes a diffuse prior for some observations and hence is not comparable to <a href="#">arima</a> nor different types of structural models. |
| <code>loglik0</code>       | the maximized log-likelihood with the constant used prior to R 3.0.0, for backwards compatibility.  |
| <code>data</code>          | the time series <code>x</code> .  |
| <code>residuals</code>     | the standardized residuals.   |
| <code>fitted</code>        | a multiple time series with one component for the level, slope and seasonal components, estimated contemporaneously (that is at time $t$ and not at the end of the series).   |
| <code>call</code>          | the matched call.   |
| <code>series</code>        | the name of the series <code>x</code> .   |
| <code>code</code>          | the convergence code returned by <a href="#">optim</a> .  |
| <code>model, model0</code> | Lists representing the Kalman filter used in the fitting. See <a href="#">KalmanLike</a> . <code>model0</code> is the initial state of the filter, <code>model</code> its final state.  |
| <code>xtsp</code>          | the <code>tsp</code> attributes of <code>x</code> .   |

### Note

Optimization of structural models is a lot harder than many of the references admit. For example, the [AirPassengers](#) data are considered in Brockwell & Davis (1996): their solution appears to be a local maximum, but nowhere near as good a fit as that produced by `StructTS`. It is quite common to find fits with one or more variances zero, and this can include  $\sigma_\epsilon^2$ .

```

summary.aov

*Summarize an Analysis of Variance Model*

## Description

Summarize an analysis of variance model.

## Usage

```
## S3 method for class 'aov'
summary(object, intercept = FALSE, split,
        expand.split = TRUE, keep.zero.df = TRUE, ...)

## S3 method for class 'aovlist'
summary(object, ...)
```

## Arguments

|              |  |
|--------------|--|
| object       | An object of class "aov" or "aovlist".   |
| intercept    | logical: should intercept terms be included?   |
| split        | an optional named list, with names corresponding to terms in the model. Each component is itself a list with integer components giving contrasts whose contributions are to be summed. |
| expand.split | logical: should the split apply also to interactions involving the factor?   |
| keep.zero.df | logical: should terms with no degrees of freedom be included?  |
| ...          | Arguments to be passed to or from other methods, for summary.aovlist including those for summary.aov.  |

**Value**

An object of class `c("summary.aov", "listof")` or `"summary.aovlist"` respectively.

For fits with a single stratum the result will be a list of ANOVA tables, one for each response (even if there is only one response): the tables are of class `"anova"` inheriting from class `"data.frame"`. They have columns `"Df"`, `"Sum Sq"`, `"Mean Sq"`, as well as `"F value"` and `"Pr(>F)"` if there are non-zero residual degrees of freedom. There is a row for each term in the model, plus one for `"Residuals"` if there are any.

For multistratum fits the return value is a list of such summaries, one for each stratum.

**Note**

The use of `expand.split = TRUE` is little tested: it is always possible to set it to `FALSE` and specify exactly all the splits required.

**See Also**

**Examples**

```
## For a simple example see example(aov)

# Cochran and Cox (1957, p.164)
# 3x3 factorial with ordered factors, each is average of 12.
CC <- data.frame(
  y = c(449, 413, 326, 409, 358, 291, 341, 278, 312)/12,
  P = ordered(gl(3, 3)), N = ordered(gl(3, 1, 9))
)
CC.aov <- aov(y ~ N * P, data = CC, weights = rep(12, 9))
summary(CC.aov)

# Split both main effects into linear and quadratic parts.
summary(CC.aov, split = list(N = list(L = 1, Q = 2),
                              P = list(L = 1, Q = 2)))

# Split only the interaction
summary(CC.aov, split = list("N:P" = list(L.L = 1, Q = 2:4)))

# split on just one var
summary(CC.aov, split = list(P = list(lin = 1, quad = 2)))
summary(CC.aov, split = list(P = list(lin = 1, quad = 2)),
        expand.split = FALSE)
```

**Description**

These functions are all [methods](#) for class `glm` or `summary.glm` objects.

## Usage

```
## S3 method for class 'glm'
summary(object, dispersion = NULL, correlation = FALSE,
        symbolic.cor = FALSE, ...)

## S3 method for class 'summary.glm'
print(x, digits = max(3, getOption("digits") - 3),
      symbolic.cor = x$symbolic.cor,
      signif.stars = getOption("show.signif.stars"),
      show.residuals = FALSE, ...)
```

## Arguments

|                             |  |
|-----------------------------|--|
| <code>object</code>         | an object of class "glm", usually, a result of a call to <a href="#">glm</a> .   |
| <code>x</code>              | an object of class "summary.glm", usually, a result of a call to <code>summary.glm</code> .  |
| <code>dispersion</code>     | the dispersion parameter for the family used. Either a single numerical value or NULL (the default), when it is inferred from <code>object</code> (see ‘Details’). |
| <code>correlation</code>    | logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.  |
| <code>digits</code>         | the number of significant digits to use when printing.   |
| <code>symbolic.cor</code>   | logical. If TRUE, print the correlations in a symbolic form (see <a href="#">symnum</a> ) rather than as numbers.  |
| <code>signif.stars</code>   | logical. If TRUE, ‘significance stars’ are printed for each coefficient.   |
| <code>show.residuals</code> | logical. If TRUE then a summary of the deviance residuals is printed at the head of the output.  |
| <code>...</code>            | further arguments passed to or from other methods.   |

## Details

`print.summary.glm` tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives ‘significance stars’ if `signif.stars` is TRUE. The coefficients component of the result gives the estimated coefficients and their estimated standard errors, together with their ratio. This third column is labelled `t ratio` if the dispersion is estimated, and `z ratio` if the dispersion is known (or fixed by the family). A fourth column gives the two-tailed p-value corresponding to the t or z ratio based on a Student t or Normal reference distribution. (It is possible that the dispersion is not known and there are no residual degrees of freedom from which to estimate it. In that case the estimate is NaN.)

Aliased coefficients are omitted in the returned object but restored by the `print` method.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print `summary(object)$correlation` directly.

The dispersion of a GLM is not used in the fitting process, but it is needed to find standard errors. If `dispersion` is not supplied or NULL, the dispersion is taken as 1 for the binomial and Poisson families, and otherwise estimated by the residual Chi-squared statistic (calculated from cases with non-zero weights) divided by the residual degrees of freedom.

`summary` can be used with Gaussian `glm` fits to handle the case of a linear regression with known error variance, something not handled by [summary.lm](#).

**Value**

`summary.glm` returns an object of class "`summary.glm`", a list with components

|                             |  |
|-----------------------------|--|
| <code>call</code>           | the component from object.   |
| <code>family</code>         | the component from object.   |
| <code>deviance</code>       | the component from object.   |
| <code>contrasts</code>      | the component from object.   |
| <code>df.residual</code>    | the component from object.   |
| <code>null.deviance</code>  | the component from object.   |
| <code>df.null</code>        | the component from object.   |
| <code>deviance.resid</code> | the deviance residuals: see <a href="#">residuals.glm</a> .  |
| <code>coefficients</code>   | the matrix of coefficients, standard errors, z-values and p-values. Aliased coefficients are omitted.                                    |
| <code>aliased</code>        | named logical vector showing if the original coefficients are aliased.   |
| <code>dispersion</code>     | either the supplied argument or the inferred/estimated dispersion if the former is NULL.   |
| <code>df</code>             | a 3-vector of the rank of the model and the number of residual degrees of freedom, plus number of coefficients (including aliased ones). |
| <code>cov.unscaled</code>   | the unscaled (dispersion = 1) estimated covariance matrix of the estimated coefficients.   |
| <code>cov.scaled</code>     | ditto, scaled by dispersion.   |
| <code>correlation</code>    | (only if <code>correlation</code> is true.) The estimated correlations of the estimated coefficients.                                    |
| <code>symbolic.cor</code>   | (only if <code>correlation</code> is true.) The value of the argument <code>symbolic.cor</code> .  |

`summary.lm`

*Summarizing Linear Model Fits*

---

**Description**

`summary` method for class "`lm`".

**Usage**

```
## S3 method for class 'lm'
summary(object, correlation = FALSE, symbolic.cor = FALSE, ...)

## S3 method for class 'summary.lm'
print(x, digits = max(3, getOption("digits") - 3),
      symbolic.cor = x$symbolic.cor,
      signif.stars = getOption("show.signif.stars"), ...)
```

**Arguments**

|                           |  |
|---------------------------|--|
| <code>object</code>       | an object of class "lm", usually, a result of a call to <code>lm</code> .                                      |
| <code>x</code>            | an object of class "summary.lm", usually, a result of a call to <code>summary.lm</code> .                      |
| <code>correlation</code>  | logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.                  |
| <code>digits</code>       | the number of significant digits to use when printing.   |
| <code>symbolic.cor</code> | logical. If TRUE, print the correlations in a symbolic form (see <code>symnum</code> ) rather than as numbers. |
| <code>signif.stars</code> | logical. If TRUE, 'significance stars' are printed for each coefficient.                                       |
| <code>...</code>          | further arguments passed to or from other methods.   |

**Details**

`print.summary.lm` tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives 'significance stars' if `signif.stars` is TRUE.

Aliased coefficients are omitted in the returned object but restored by the `print` method.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print `summary(object)$correlation` directly.

**Value**

The function `summary.lm` computes and returns a list of summary statistics of the fitted linear model given in `object`, using the components (list elements) "call" and "terms" from its argument, plus

|                           |  |
|---------------------------|--|
| <code>residuals</code>    | the <i>weighted</i> residuals, the usual residuals rescaled by the square root of the weights specified in the call to <code>lm</code> .                                   |
| <code>coefficients</code> | a $p \times 4$ matrix with columns for the estimated coefficient, its standard error, t-statistic and corresponding (two-sided) p-value. Aliased coefficients are omitted. |
| <code>aliased</code>      | named logical vector showing if the original coefficients are aliased.   |
| <code>sigma</code>        | the square root of the estimated variance of the random error  |

$$\hat{\sigma}^2 = \frac{1}{n-p} \sum_i w_i R_i^2,$$

where  $R_i$  is the  $i$ -th residual, `residuals[i]`.

|                 |   |
|-----------------|---|
| <code>df</code> | degrees of freedom, a 3-vector $(p, n-p, p^*)$ , the first being the number of non-aliased coefficients, the last being the total number of coefficients. |
|-----------------|---|

`fstatistic` (for models including non-intercept terms) a 3-vector with the value of the F-statistic with its numerator and denominator degrees of freedom.

`r.squared`  $R^2$ , the ‘fraction of variance explained by the model’,

$$R^2 = 1 - \frac{\sum_i R_i^2}{\sum_i (y_i - y^*)^2},$$

where  $y^*$  is the mean of  $y_i$  if there is an intercept and zero otherwise.

`adj.r.squared`

the above  $R^2$  statistic ‘adjusted’, penalizing for higher  $p$ .

`cov.unscaled` a  $p \times p$  matrix of (unscaled) covariances of the  $\hat{\beta}_j, j = 1, \dots, p$ .

`correlation` the correlation matrix corresponding to the above `cov.unscaled`, if `correlation = TRUE` is specified.

`symbolic.cor` (only if `correlation` is true.) The value of the argument `symbolic.cor`.

`na.action` from object, if present there.

## See Also

The model fitting function [lm](#), [summary](#).

Function [coef](#) will extract the matrix of coefficients with standard errors, t-statistics and p-values.

## Examples

```
##-- Continuing the lm(.) example:
coef(lm.D90) # the bare coefficients
sld90 <- summary(lm.D90 <- lm(weight ~ group -1)) # omitting intercept
sld90
coef(sld90) # much more

## model with *aliased* coefficient:
lm.D9. <- lm(weight ~ group + I(group != "Ctl"))
Sm.D9. <- summary(lm.D9.)
Sm.D9. # shows the NA NA NA NA line
stopifnot(length(cc <- coef(lm.D9.)) == 3, is.na(cc[3]),
           dim(coef(Sm.D9.)) == c(2,4), Sm.D9.$df == c(2, 18, 3))
```

---

summary.manova

*Summary Method for Multivariate Analysis of Variance*

---

## Description

A summary method for class "manova".

## Usage

```
## S3 method for class 'manova'
summary(object,
        test = c("Pillai", "Wilks", "Hotelling-Lawley", "Roy"),
        intercept = FALSE, tol = 1e-7, ...)
```

## Arguments

|                        |   |
|------------------------|---|
| <code>object</code>    | An object of class "manova" or an aov object with multiple responses.                               |
| <code>test</code>      | The name of the test statistic to be used. Partial matching is used so the name can be abbreviated. |
| <code>intercept</code> | logical. If TRUE, the intercept term is included in the table.                                      |
| <code>tol</code>       | tolerance to be used in deciding if the residuals are rank-deficient: see <a href="#">qr</a> .      |
| <code>...</code>       | further arguments passed to or from other methods.  |

## Details

The `summary.manova` method uses a multivariate test statistic for the summary table. Wilks' statistic is most popular in the literature, but the default Pillai–Bartlett statistic is recommended by Hand and Taylor (1987).

The table gives a transformation of the test statistic which has approximately an F distribution. The approximations used follow S-PLUS and SAS (the latter apart from some cases of the Hotelling–Lawley statistic), but many other distributional approximations exist: see Anderson (1984) and Krzanowski and Marriott (1994) for further references. All four approximate F statistics are the same when the term being tested has one degree of freedom, but in other cases that for the Roy statistic is an upper bound.

The tolerance `tol` is applied to the QR decomposition of the residual correlation matrix (unless some response has essentially zero residuals, when it is unscaled). Thus the default value guards against very highly correlated responses: it can be reduced but doing so will allow rather inaccurate results and it will normally be better to transform the responses to remove the high correlation.

## Value

An object of class "summary.manova". If there is a positive residual degrees of freedom, this is a list with components

|                          |   |
|--------------------------|---|
| <code>row.names</code>   | The names of the terms, the row names of the <code>stats</code> table if present. |
| <code>SS</code>          | A named list of sums of squares and product matrices.                             |
| <code>Eigenvalues</code> | A matrix of eigenvalues.  |
| <code>stats</code>       | A matrix of the statistics, approximate F value, degrees of freedom and P value.  |

otherwise components `row.names`, `SS` and `Df` (degrees of freedom) for the terms (and not the residuals).

summary(fit)               # same F statistics as single-df terms
```

---

summary.nls

*Summarizing Non-Linear Least-Squares Model Fits*

---

## Description

summary method for class "nls".

## Usage

```
## S3 method for class 'nls'
summary(object, correlation = FALSE, symbolic.cor = FALSE, ...)

## S3 method for class 'summary.nls'
print(x, digits = max(3, getOption("digits") - 3),
      symbolic.cor = x$symbolic.cor,
      signif.stars = getOption("show.signif.stars"), ...)
```

## Arguments

|              |   |
|--------------|---|
| object       | an object of class "nls".   |
| x            | an object of class "summary.nls", usually the result of a call to summary.nls.                                    |
| correlation  | logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.                     |
| digits       | the number of significant digits to use when printing.  |
| symbolic.cor | logical. If TRUE, print the correlations in a symbolic form (see <a href="#">symnum</a> ) rather than as numbers. |
| signif.stars | logical. If TRUE, 'significance stars' are printed for each coefficient.  |
| ...          | further arguments passed to or from other methods.  |

## Details

The distribution theory used to find the distribution of the standard errors and of the residual standard error (for t ratios) is based on linearization and is approximate, maybe very approximate.

`print.summary.nls` tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives ‘significance stars’ if `signif.stars` is `TRUE`.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print `summary(object)$correlation` directly.

## Value

The function `summary.nls` computes and returns a list of summary statistics of the fitted model given in `object`, using the component `"formula"` from its argument, plus

`residuals` the *weighted* residuals, the usual residuals rescaled by the square root of the weights specified in the call to `nls`.  
`coefficients` a  $p \times 4$  matrix with columns for the estimated coefficient, its standard error, t-statistic and corresponding (two-sided) p-value.  
`sigma` the square root of the estimated variance of the random error

$$\hat{\sigma}^2 = \frac{1}{n-p} \sum_i R_i^2,$$

where  $R_i$  is the  $i$ -th weighted residual.

`df` degrees of freedom, a 2-vector  $(p, n-p)$ . (Here and elsewhere  $n$  omits observations with zero weights.)  
`cov.unscaled` a  $p \times p$  matrix of (unscaled) covariances of the parameter estimates.  
`correlation` the correlation matrix corresponding to the above `cov.unscaled`, if `correlation = TRUE` is specified and there are a non-zero number of residual degrees of freedom.  
`symbolic.cor` (only if `correlation` is true.) The value of the argument `symbolic.cor`.

## See Also

The model fitting function `nls`, `summary`.

Function `coef` will extract the matrix of coefficients with standard errors, t-statistics and p-values.

|-------------------------------|---|
| <code>summary.princomp</code> | <i>Summary method for Principal Components Analysis</i> |
|-------------------------------|---|

---

## Description

The `summary` method for class `"princomp"`.

## Usage

```
## S3 method for class 'princomp'
summary(object, loadings = FALSE, cutoff = 0.1, ...)

## S3 method for class 'summary.princomp'
print(x, digits = 3, loadings = x$print.loadings,
      cutoff = x$cutoff, ...)
```

Arguments

|          |   |
|----------|---|
| object   | an object of class "princomp", as from princomp().                                      |
| loadings | logical. Should loadings be included?   |
| cutoff   | numeric. Loadings below this cutoff in absolute value are shown as blank in the output. |
| x        | an object of class "summary.princomp".  |
| digits   | the number of significant digits to be used in listing loadings.                        |
| ...      | arguments to be passed to or from other methods.  |

Value

object with additional components cutoff and print.loadings.

[princomp](#)

Examples

```
summary(pc.cr <- princomp(USArrests, cor = TRUE))
## The signs of the loading columns are arbitrary
print(summary(princomp(USArrests, cor = TRUE),
  loadings = TRUE, cutoff = 0.2), digits = 2)
```

---

|        |                                 |
|--------|---------------------------------|
| supsmu | <i>Friedman’s SuperSmoother</i> |
|--------|---------------------------------|

---

Description

Smooth the (x, y) values by Friedman’s ‘super smoother’.

Usage

```
supsmu(x, y, wt =, span = "cv", periodic = FALSE, bass = 0, trace = FALSE)
```

Arguments

|          |   |
|----------|---|
| x        | x values for smoothing  |
| y        | y values for smoothing  |
| wt       | case weights, by default all equal  |
| span     | the fraction of the observations in the span of the running lines smoother, or "cv" to choose this by leave-one-out cross-validation. |
| periodic | if TRUE, the x values are assumed to be in [0, 1] and of period 1.  |
| bass     | controls the smoothness of the fitted curve. Values of up to 10 indicate increasing smoothness.                                       |
| trace    | logical, if true, prints one line of info “per spar”, notably useful for "cv".  |

## Details

supsmu is a running lines smoother which chooses between three spans for the lines. The running lines smoothers are symmetric, with  $k/2$  data points each side of the predicted point, and values of  $k$  as  $0.5 * n$ ,  $0.2 * n$  and  $0.05 * n$ , where  $n$  is the number of data points. If `span` is specified, a single smoother with span  $\text{span} * n$  is used.

The best of the three smoothers is chosen by cross-validation for each prediction. The best spans are then smoothed by a running lines smoother and the final prediction chosen by linear interpolation.

The FORTRAN code says: “For small samples ( $n < 40$ ) or if there are substantial serial correlations between observations close in x-value, then a pre-specified fixed span smoother ( $\text{span} > 0$ ) should be used. Reasonable span values are 0.2 to 0.4.”

Cases with non-finite values of `x`, `y` or `wt` are dropped, with a warning.

## Value

A list with components

|                |   |
|----------------|---|
| <code>x</code> | the input values in increasing order with duplicates removed. |
| <code>y</code> | the corresponding y values on the fitted curve.               |

---

symnum

*Symbolic Number Coding*

---

## Description

Symbolically encode a given numeric or logical vector or array. Particularly useful for visualization of structured matrices, e.g., correlation, sparse, or logical ones.

## Usage

```
symnum(x, cutpoints = c(0.3, 0.6, 0.8, 0.9, 0.95),
       symbols = if(numeric.x) c(" ", ".", ",", "+", "*", "B")
       else c(".", "|"),
       legend = length(symbols) >= 3,
       na = "?", eps = 1e-5, numeric.x = is.numeric(x),
       corr = missing(cutpoints) && numeric.x,
       show.max = if(corr) "1", show.min = NULL,
       abbr.colnames = has.colnames,
       lower.triangular = corr && is.numeric(x) && is.matrix(x),
       diag.lower.tri = corr && !is.null(show.max))
```

## Arguments

|                               |  |
|-------------------------------|--|
| <code>x</code>                | numeric or logical vector or array.  |
| <code>cutpoints</code>        | numeric vector whose values <code>cutpoints[j] = c<sub>j</sub></code> ( <i>after</i> augmentation, see <code>corr</code> below) are used for intervals.  |
| <code>symbols</code>          | character vector, one shorter than (the <i>augmented</i> , see <code>corr</code> below) <code>cutpoints</code> . <code>symbols[j] = s<sub>j</sub></code> are used as ‘code’ for the (half open) interval $(c_j, c_{j+1}]$ .<br>When <code>numeric.x</code> is FALSE, i.e., by default when argument <code>x</code> is logical, the default is <code>c(" ", " ")</code> (graphical 0/1 s).              |
| <code>legend</code>           | logical indicating if a "legend" attribute is desired.   |
| <code>na</code>               | character or logical. How NAs are coded. If <code>na == FALSE</code> , NAs are coded invisibly, <i>including</i> the "legend" attribute below, which otherwise mentions NA coding.   |
| <code>eps</code>              | absolute precision to be used at left and right boundary.  |
| <code>numeric.x</code>        | logical indicating if <code>x</code> should be treated as numbers, otherwise as logical.   |
| <code>corr</code>             | logical. If TRUE, <code>x</code> contains correlations. The cutpoints are augmented by 0 and 1 and <code>abs(x)</code> is coded.   |
| <code>show.max</code>         | if TRUE, or of mode character, the maximal cutpoint is coded especially.   |
| <code>show.min</code>         | if TRUE, or of mode character, the minimal cutpoint is coded especially.   |
| <code>abbr.colnames</code>    | logical, integer or NULL indicating how column names should be abbreviated (if they are); if NULL (or FALSE and <code>x</code> has no column names), the column names will all be empty, i.e., ""; otherwise if <code>abbr.colnames</code> is false, they are left unchanged. If TRUE or integer, existing column names will be abbreviated to <code>abbreviate(*, minlength = abbr.colnames)</code> . |
| <code>lower.triangular</code> | logical. If TRUE and <code>x</code> is a matrix, only the <i>lower triangular</i> part of the matrix is coded as non-blank.  |
| <code>diag.lower.tri</code>   | logical. If <code>lower.triangular</code> <i>and</i> this are TRUE, the <i>diagonal</i> part of the matrix is shown.   |

## Value

An atomic character object of class `noquote` and the same dimensions as `x`.

If legend is TRUE (as by default when there are more than two classes), the result has an attribute "legend" containing a legend of the returned character codes, in the form

$$c_1 s_1 c_2 s_2 \dots s_n c_{n+1}$$

where  $c_j = \text{cutpoints}[j]$  and  $s_j = \text{symbols}[j]$ .

### Note

The optional (mostly logical) arguments all try to use smart defaults. Specifying them explicitly may lead to considerably improved output in many cases.

```

---

t.test

---

*Student's t-Test*

---

**Description**

Performs one and two sample t-tests on vectors of data.

**Usage**

```
t.test(x, ...)

## Default S3 method:
t.test(x, y = NULL,
       alternative = c("two.sided", "less", "greater"),
       mu = 0, paired = FALSE, var.equal = FALSE,
       conf.level = 0.95, ...)

## S3 method for class 'formula'
t.test(formula, data, subset, na.action = na.pass, ...)
```

**Arguments**

|             |  |
|-------------|--|
| x           | a (non-empty) numeric vector of data values.   |
| y           | an optional (non-empty) numeric vector of data values.   |
| alternative | a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.  |
| mu          | a number indicating the true value of the mean (or difference in means if you are performing a two sample test).   |
| paired      | a logical indicating whether you want a paired t-test.   |
| var.equal   | a logical variable indicating whether to treat the two variances as being equal. If TRUE then the pooled variance is used to estimate the variance otherwise the Welch (or Satterthwaite) approximation to the degrees of freedom is used.   |
| conf.level  | confidence level of the interval.  |
| formula     | a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> is a numeric variable giving the data values and <code>rhs</code> either 1 for a one-sample or paired test or a factor with two levels giving the corresponding groups. If <code>lhs</code> is of class "Pair" and <code>rhs</code> is 1, a paired test is done, see Examples. |
| data        | an optional matrix or data frame (or similar: see <code>model.frame</code> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .  |
| subset      | an optional vector specifying a subset of observations to be used.   |
| na.action   | a function which indicates what should happen when the data contain NAs.   |
| ...         | further arguments to be passed to or from methods. For the <code>formula</code> method, this includes arguments of the default method, but not <code>paired</code> .   |

## Details

`alternative = "greater"` is the alternative that `x` has a larger mean than `y`. For the one-sample case: that the mean is positive.

If `paired` is `TRUE` then both `x` and `y` must be specified and they must be the same length. Missing values are silently removed (in pairs if `paired` is `TRUE`). If `var.equal` is `TRUE` then the pooled estimate of the variance is used. By default, if `var.equal` is `FALSE` then the variance is estimated separately for both groups and the Welch modification to the degrees of freedom is used.

If the input data are effectively constant (compared to the larger of the two means) an error is generated.

## Value

A list with class `"htest"` containing the following components:

|                          |   |
|--------------------------|---|
| <code>statistic</code>   | the value of the t-statistic.   |
| <code>parameter</code>   | the degrees of freedom for the t-statistic.   |
| <code>p.value</code>     | the p-value for the test.   |
| <code>conf.int</code>    | a confidence interval for the mean appropriate to the specified alternative hypothesis.   |
| <code>estimate</code>    | the estimated mean or difference in means depending on whether it was a one-sample test or a two-sample test.                       |
| <code>null.value</code>  | the specified hypothesized value of the mean or mean difference depending on whether it was a one-sample test or a two-sample test. |
| <code>stderr</code>      | the standard error of the mean (difference), used as denominator in the t-statistic formula.  |
| <code>alternative</code> | a character string describing the alternative hypothesis.   |
| <code>method</code>      | a character string indicating what type of t-test was performed.  |
| <code>data.name</code>   | a character string giving the name(s) of the data.  |

[prop.test](#)

## Examples

```
## Two-sample t-test
t.test(1:10, y = c(7:20))      # P = .00001855
t.test(1:10, y = c(7:20, 200)) # P = .1245      -- NOT significant anymore

## Traditional interface
with(mtcars, t.test(mpg[am == 0], mpg[am == 1]))

## Formula interface
t.test(mpg ~ am, data = mtcars)

## One-sample t-test
## Traditional interface
t.test(sleep$extra)

## Formula interface
t.test(extra ~ 1, data = sleep)
```

```
## Paired t-test
## The sleep data is actually paired, so could have been in wide format:
sleep2 <- reshape(sleep, direction = "wide",
                  idvar = "ID", timevar = "group")

## Traditional interface
t.test(sleep2$extra.1, sleep2$extra.2, paired = TRUE)

## Formula interface
t.test(Pair(extra.1, extra.2) ~ 1, data = sleep2)
```

TDist

*The Student t Distribution*

## Description

Density, distribution function, quantile function and random generation for the  $t$  distribution with `df` degrees of freedom (and optional non-centrality parameter `ncp`).

## Usage

```
dt(x, df, ncp, log = FALSE)
pt(q, df, ncp, lower.tail = TRUE, log.p = FALSE)
qt(p, df, ncp, lower.tail = TRUE, log.p = FALSE)
rt(n, df, ncp)
```

## Arguments

|                         |  |
|-------------------------|--|
| <code>x, q</code>       | vector of quantiles.   |
| <code>p</code>          | vector of probabilities.   |
| <code>n</code>          | number of observations. If <code>length(n) &gt; 1</code> , the length is taken to be the number required.  |
| <code>df</code>         | degrees of freedom ( $> 0$ , maybe non-integer). <code>df = Inf</code> is allowed.   |
| <code>ncp</code>        | non-centrality parameter $\delta$ ; currently except for <code>rt()</code> , accurate only for <code>abs(ncp) &lt;= 37.62</code> . If omitted, use the central $t$ distribution. |
| <code>log, log.p</code> | logical; if TRUE, probabilities <code>p</code> are given as <code>log(p)</code> .  |
| <code>lower.tail</code> | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .  |

## Details

The  $t$  distribution with `df` =  $\nu$  degrees of freedom has density

$$f(x) = \frac{\Gamma((\nu+1)/2)}{\sqrt{\pi\nu}\Gamma(\nu/2)}(1+x^2/\nu)^{-(\nu+1)/2}$$

for all real  $x$ . It has mean 0 (for  $\nu > 1$ ) and variance  $\frac{\nu}{\nu-2}$  (for  $\nu > 2$ ).

The general *non-central t* with parameters  $(\nu, \delta) = (\text{df}, \text{ncp})$  is defined as the distribution of  $T_\nu(\delta) := (U + \delta)/\sqrt{V/\nu}$  where  $U$  and  $V$  are independent random variables,  $U \sim \mathcal{N}(0, 1)$  and  $V \sim \chi_\nu^2$  (see [Chisquare](#)).

The most used applications are power calculations for  $t$ -tests:

Let  $T = \frac{\bar{X} - \mu_0}{S/\sqrt{n}}$  where  $\bar{X}$  is the [mean](#) and  $S$  the sample standard deviation ([sd](#)) of  $X_1, X_2, \dots, X_n$  which are i.i.d.  $\mathcal{N}(\mu, \sigma^2)$ . Then  $T$  is distributed as non-central  $t$  with  $\text{df} = n - 1$  degrees of freedom and non-centrality parameter  $\text{ncp} = (\mu - \mu_0)\sqrt{n}/\sigma$ .

The  $t$  distribution's cumulative distribution function (cdf),  $F_\nu$  fulfills  $F_\nu(t) = \frac{1}{2}I_x(\frac{\nu}{2}, \frac{1}{2})$ , for  $t \leq 0$ , and  $F_\nu(t) = 1 - \frac{1}{2}I_x(\frac{\nu}{2}, \frac{1}{2})$ , for  $t \geq 0$ , where  $x := \nu/(\nu + t^2)$ , and  $I_x(a, b)$  is the incomplete beta function, in R this is [pbeta](#) ( $x$ ,  $a$ ,  $b$ ).

## Value

`dt` gives the density, `pt` gives the distribution function, `qt` gives the quantile function, and `rt` generates random deviates.

Invalid arguments will result in return value `NaN`, with a warning.

The length of the result is determined by `n` for `rt`, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than `n` are recycled to the length of the result. Only the first elements of the logical arguments are used.

## Note

Supplying `ncp = 0` uses the algorithm for the non-central distribution, which is not the same algorithm used if `ncp` is omitted. This is to give consistent behaviour in extreme cases with values of `ncp` very near zero.

The code for non-zero `ncp` is principally intended to be used for moderate values of `ncp`: it will not be highly accurate, especially in the tails, for large values.

## Source

The central `dt` is computed via an accurate formula provided by Catherine Loader (see the reference in [dbinom](#)).

For the non-central case of `dt`, C code contributed by Claus Ekstrøm based on the relationship (for  $x \neq 0$ ) to the cumulative distribution.

For the central case of `pt`, a normal approximation in the tails, otherwise via [pbeta](#).

For the non-central case of `pt` based on a C translation of

Lenth, R. V. (1989). *Algorithm AS 243* — Cumulative distribution function of the non-central  $t$  distribution, *Applied Statistics* **38**, 185–189.

This computes the lower tail only, so the upper tail currently suffers from cancellation and a warning will be given when this is likely to be significant.

For central `qt`, a C translation of

Hill, G. W. (1970) Algorithm 396: Student's  $t$ -quantiles. *Communications of the ACM*, **13**(10), 619–620.

altered to take account of

Hill, G. W. (1981) Remark on Algorithm 396, *ACM Transactions on Mathematical Software*, **7**, 250–1.

The non-central case is done by inversion.

termplot

---

*Plot Regression Terms*

---

## Description

Plots regression terms against their predictors, optionally with standard errors and partial residuals added.

## Usage

```
termplot(model, data = NULL, envir = environment(formula(model)),
  partial.resid = FALSE, rug = FALSE,
  terms = NULL, se = FALSE,
  xlabs = NULL, ylabs = NULL, main = NULL,
  col.term = 2, lwd.term = 1.5,
  col.se = "orange", lty.se = 2, lwd.se = 1,
  col.res = "gray", cex = 1, pch = par("pch"),
  col.smth = "darkred", lty.smth = 2, span.smth = 2/3,
  ask = dev.interactive() && nb.fig < n.tms,
  use.factor.levels = TRUE, smooth = NULL, ylim = "common",
  plot = TRUE, transform.x = FALSE, ...)
```

## Arguments

|                               |  |
|-------------------------------|--|
| model                         | fitted model object  |
| data                          | data frame in which variables in model can be found  |
| envir                         | environment in which variables in model can be found   |
| partial.resid                 | logical; should partial residuals be plotted?  |
| rug                           | add <a href="#">rugplots</a> (jittered 1-d histograms) to the axes?  |
| terms                         | which terms to plot (default NULL means all terms); a vector passed to <a href="#">predict(..., type = "terms", terms = *)</a> .                           |
| se                            | plot pointwise standard errors?  |
| xlabs                         | vector of labels for the x axes  |
| ylabs                         | vector of labels for the y axes  |
| main                          | logical, or vector of main titles; if TRUE, the model's call is taken as main title, NULL or FALSE mean no titles.   |
| col.term, lwd.term            | color and line width for the 'term curve', see <a href="#">lines</a> .   |
| col.se, lty.se, lwd.se        | color, line type and line width for the 'twice-standard-error curve' when se = TRUE.   |
| col.res, cex, pch             | color, plotting character expansion and type for partial residuals, when partial.resid = TRUE, see <a href="#">points</a> .                                |
| ask                           | logical; if TRUE, the user is <i>asked</i> before each plot, see <a href="#">par(ask=.)</a> .  |
| use.factor.levels             | Should x-axis ticks use factor levels or numbers for factor terms?   |
| smooth                        | NULL or a function with the same arguments as <a href="#">panel.smooth</a> to draw a smooth through the partial residuals for non-factor terms             |
| lty.smth, col.smth, span.smth | Passed to smooth   |
| ylim                          | an optional range for the y axis, or "common" when a range sufficient for all the plot will be computed, or "free" when limits are computed for each plot. |
| plot                          | if set to FALSE plots are not produced: instead a list is returned containing the data that would have been plotted.                                       |

```
transform.x  logical vector; if an element (recycled as necessary) is TRUE, partial residuals
              for the corresponding term are plotted against transformed values. The model
              response is then a straight line, allowing a ready comparison against the data or
              against the curve obtained from smooth-panel.smooth.

...          other graphical parameters.
```

## Details

The model object must have a `predict` method that accepts `type = "terms"`, e.g., `glm` in the **stats** package, `coxph` and `survreg` in the **survival** package.

For the `partial.resid = TRUE` option model must have a `residuals` method that accepts `type = "partial"`, which `lm` and `glm` do.

The data argument should rarely be needed, but in some cases `termplot` may be unable to reconstruct the original data frame. Using `na.action=na.exclude` makes these problems less likely.

Nothing sensible happens for interaction terms, and they may cause errors.

The `plot = FALSE` option is useful when some special action is needed, e.g. to overlay the results of two different models or to plot confidence bands.

## Value

For `plot = FALSE`, a list with one element for each plot which would have been produced. Each element of the list is a data frame with variables `x`, `y`, and optionally the pointwise standard errors `se`. For continuous predictors `x` will contain the ordered unique values and for a factor it will be a factor containing one instance of each level. The list has attribute `"constant"` copied from the predicted terms object.

Otherwise, the number of terms, invisibly.

## See Also

For (generalized) linear models, `plot.lm` and `predict.glm`.

## Examples

```
require(graphics)

had.splines <- "package:splines" %in% search()
if(!had.splines) rs <- require(splines)
x <- 1:100
z <- factor(rep(LETTERS[1:4], 25))
y <- rnorm(100, sin(x/10)+as.numeric(z))
model <- glm(y ~ ns(x, 6) + z)

par(mfrow = c(2,2)) ## 2 x 2 plots for same model :
termplot(model, main = paste("termplot( ", deparse(model$call), " ...)") )
termplot(model, rug = TRUE)
termplot(model, partial.resid = TRUE, se = TRUE, main = TRUE)
termplot(model, partial.resid = TRUE, smooth = panel.smooth, span.smth = 1/4)
if(!had.splines && rs) detach("package:splines")

if(requireNamespace("MASS", quietly = TRUE)) {
  hills.lm <- lm(log(time) ~ log(climb)+log(dist), data = MASS::hills)
  termplot(hills.lm, partial.resid = TRUE, smooth = panel.smooth,
```

```

      terms = "log(dist)", main = "Original")
termplot(hills.lm, transform.x = TRUE,
         partial.resid = TRUE, smooth = panel.smooth,
         terms = "log(dist)", main = "Transformed")

}

```

terms

*Model Terms*

## Description

The function `terms` is a generic function which can be used to extract *terms* objects from various kinds of R data objects.

## Usage

```
terms(x, ...)
```

## Arguments

`x`                      object used to select a method to dispatch.  
`...`                    further arguments passed to or from other methods.

## Details

There are methods for classes "aovlist", and "terms" "formula" (see [terms.formula](#)): the default method just extracts the `terms` component of the object, or failing that a "terms" attribute (as used by [model.frame](#)).

There are [print](#) and [labels](#) methods for class "terms": the latter prints the term labels (see [terms.object](#)).

## Value

An object of class `c("terms", "formula")` which contains the *terms* representation of a symbolic model. See [terms.object](#) for its structure.

## References

Chambers, J. M. and Hastie, T. J. (1992) *Statistical models*. Chapter 2 of *Statistical Models in S* eds J. M. Chambers and T. J. Hastie, Wadsworth & Brooks/Cole.

## See Also

---

|               |  |
|---------------|--|
| terms.formula | <i>Construct a terms Object from a Formula</i> |
|---------------|--|

---

## Description

This function takes a formula and some optional arguments and constructs a terms object. The terms object can then be used to construct a [model.matrix](#).

## Usage

```
## S3 method for class 'formula'
terms(x, specials = NULL, abb = NULL, data = NULL, neg.out = TRUE,
      keep.order = FALSE, simplify = FALSE, ...,
      allowDotAsName = FALSE)
```

## Arguments

|                |   |
|----------------|---|
| x              | a <a href="#">formula</a> .   |
| specials       | which functions in the formula should be marked as special in the terms object? A character vector or NULL.   |
| abb            | Not implemented in R; deprecated.   |
| data           | a data frame from which the meaning of the special symbol . can be inferred. It is used only if there is a . in the formula.  |
| neg.out        | Not implemented in R; deprecated.   |
| keep.order     | a logical value indicating whether the terms should keep their positions. By default, when FALSE, the terms are reordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on. Effects of a given order are kept in the order specified. |
| simplify       | should the formula be expanded and simplified, the pre-1.7.0 behaviour?   |
| ...            | further arguments passed to or from other methods.  |
| allowDotAsName | normally . in a formula refers to the remaining variables contained in data. Exceptionally, . can be treated as a name for non-standard uses of formulae.   |

## Details

Not all of the options work in the same way that they do in S and not all are implemented.

## Value

A terms object is returned. It is the re-ordered formula (unless keep.order = TRUE) with several [attributes](#), see [terms.object](#) for details. In all cases variables within an interaction term in the formula are re-ordered by the ordering of the "variables" attribute, which is the order in which the variables occur in the formula.

## See Also

[terms](#), [terms.object](#), also for examples.

terms.object

*Description of Terms Objects***Description**

An object of class `terms` holds information about a model. Usually the model was specified in terms of a `formula` and that formula was used to determine the terms object.

**Details**

The object itself is simply the result of `terms.formula(<formula>)`. It has a number of attributes and they are used to construct the model frame:

`factors` An integer matrix of variables by terms showing which variables appear in which terms.

The entries are

- 0** if the variable does not occur in the term,
- 1** if it does occur and should be coded by contrasts, and
- 2** if it occurs and should be coded via dummy variables for all levels (as when a lower-order term is missing).

Note that variables in main effects always receive 1, even if the intercept is missing (in which case the first one should be coded with dummy variables). If there are no terms other than an intercept and offsets, this is `integer(0)`.

`term.labels` A character vector containing the labels for each of the terms in the model, except for offsets. Note that these are after possible re-ordering of terms.

Non-syntactic names will be quoted by backticks: this makes it easier to re-construct the formula from the term labels.

`variables` A call to `list` of the variables in the model.

`intercept` Either 0, indicating no intercept is to be fit, or 1 indicating that an intercept is to be fit.

`order` A vector of the same length as `term.labels` indicating the order of interaction for each term.

`response` The index of the variable (in `variables`) of the response (the left hand side of the formula). Zero, if there is no response.

`offset` If the model contains `offset` terms there is an `offset` attribute indicating which variable(s) are offsets

`specials` If a `specials` argument was given to `terms.formula` there is a `specials` attribute, a pairlist of vectors (one for each specified special function) giving numeric indices of the arguments of the list returned as the `variables` attribute which contain these special functions.

`dataClasses` optional. A named character vector giving the classes (as given by `.MFclass`) of the variables used in a fit.

`predvars` optional. An expression to help in computing predictions at new covariate values; see `makepredictcall`.

The object has class `c("terms", "formula")`.

**Note**

These objects are different from those found in *S*. In particular there is no `formula` attribute: instead the object is itself a formula. (Thus, the mode of a terms object is different.)

Examples of the `specials` argument can be seen in the `aov` and `coxph` functions, the latter from package **survival**.

**See Also**

`terms`, `formula`.

**Examples**

```
## use of specials (as used for gam() in packages mgcv and gam)
(tf <- terms(y ~ x + x:z + s(x), specials = "s"))
## Note that the "factors" attribute has variables as row names
## and term labels as column names, both as character vectors.
attr(tf, "specials")      # index 's' variable(s)
rownames(attr(tf, "factors"))[attr(tf, "specials")$s]

## we can keep the order by
terms(y ~ x + x:z + s(x), specials = "s", keep.order = TRUE)
```

---

time

*Sampling Times of Time Series*

---

**Description**

`time` creates the vector of times at which a time series was sampled.

`cycle` gives the positions in the cycle of each observation.

`frequency` returns the number of samples per unit time and `deltat` the time interval between observations (see `ts`).

**Usage**

```
time(x, ...)
## Default S3 method:
time(x, offset = 0, ts.eps = getOption("ts.eps"), ...)

cycle(x, ...)
frequency(x, ...)
deltat(x, ...)
```

**Arguments**

|                     |  |
|---------------------|--|
| <code>x</code>      | a univariate or multivariate time-series, or a vector or matrix.   |
| <code>offset</code> | can be used to indicate when sampling took place in the time unit. 0 (the default) indicates the start of the unit, 0.5 the middle and 1 the end of the interval.  |
| <code>ts.eps</code> | time series comparison tolerance, used in <code>time()</code> to determine if values close than <code>ts.eps</code> to an integer should be <code>round()</code> ed to it in order to preserve the “year”. |
| <code>...</code>    | extra arguments for future methods.  |

## Details

These are all generic functions, which will use the `tsp` attribute of `x` if it exists. `time` and `cycle` have methods for class `ts` that coerce the result to that class.

`time()` `round()`s values close to an integer, i.e., closer than `ts.eps`, since R 4.3.0. For previous behaviour, you can call it with `ts.eps = 0`.

## References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

## See Also

`ts`, `start`, `tsp`, `window`.

`date` for clock time, `system.time` for CPU usage.

## Examples

```
require(graphics)

cycle(presidents)
# a simple series plot
plot(as.vector(time(presidents)), as.vector(presidents), type = "l")
```

---

toeplitz

---

*Create Symmetric and Asymmetric Toeplitz Matrix*

---

## Description

In its simplest use, `toeplitz()` forms a symmetric Toeplitz matrix given its first column (or row). For the general case, asymmetric and non-square Toeplitz matrices are formed either by specifying the first column and row separately,

```
T1 <- toeplitz(col, row)
```

or by

```
T <- toeplitz2(x, nr, nc)
```

where only one of `(nr, nc)` needs to be specified. In the latter case, the simple equivalence  $T_{i,j} = x_{i-j+n_c}$  is fulfilled where  $n_c = \text{ncol}(T)$ .

## Usage

```
toeplitz(x, r = NULL, symmetric = is.null(r))
toeplitz2(x, nrow = length(x) + 1 - ncol, ncol = length(x) + 1 - nrow)
```

**Arguments**

`x` for `toeplitz(x, *)`: the first column of the Toeplitz matrix; for `toeplitz2(x, *)` it is the upper-and-left border of the Toeplitz matrix, i.e., from top-right to bottom-left, such that  $T[i, j] == x[i-j + ncol]$ .

`r` the first row of the target Toeplitz matrix; only needed in asymmetric cases.

`symmetric` optional **logical** indicating if the matrix should be symmetric.

`nrow, ncol` the number of rows and columns; only one needs to be specified.

**Value**

The  $n \times m$  Toeplitz matrix  $T$ ; for

`toeplitz()`: `dim(T)` is  $(n, m)$  and  $m == \text{length}(x)$  and  $n == m$  in the symmetric case or  $n == \text{length}(r)$  otherwise.

`toeplitz2()`: `dim(T) == c(nrow, ncol)`.

**Author(s)**

A. Trapletti and Martin Maechler (speedup and asymmetric extensions)

**Examples**

```
x <- 1:5
toeplitz(x)

T. <- toeplitz(1:5, 11:13) # with a *Warning* x[1] != r[1]
T2 <- toeplitz2(c(13:12, 1:5), 5, 3) # this is the same matrix:
stopifnot(identical(T., T2))

# Matrix of character (could also have logical, raw, complex ..) {also warning}:
noquote(toeplitz(letters[1:4], LETTERS[20:26]))

## A convolution/smoothing weight matrix :
m <- 17
k <- length(wts <- c(76, 99, 60, 20, 1))
n <- m-k+1
## Convolution
W <- toeplitz2(c(rep(0, m-k), wts, rep(0, m-k)), ncol=n)

## "display" nicely :
if(requireNamespace("Matrix"))
  print(Matrix::Matrix(W)) else {
  colnames(W) <- paste0(" ", if(n <= 9) 1:n else c(1:9, letters[seq_len(n-9)]))
  print(W)
}

## scale W to have column sums 1:
W. <- W / sum(wts)
all.equal(rep(1, ncol(W.)), colSums(W.), check.attributes = FALSE)
## Visualize "mass-preserving" convolution
x <- 1:n; f <- function(x) exp(-(x - .4*n)/3)^2
y <- f(x) + rep_len(3:-2, n)/10
## Smoothing convolution:
y.hat <- W. %*% y # y.hat := smoothed(y) ("mass preserving" -> longer than y)
```

```

stopifnot(length(y.hat) == m, m == n + (k-1))
plot(x,y, type="b", xlim=c(1,m)); curve(f(x), 1,n, col="gray", lty=2, add=TRUE)
lines(1:m, y.hat, col=2, lwd=3)
rbind(sum(y), sum(y.hat)) ## mass preserved

## And, yes, convolve(y, *) does the same when called appropriately:
all.equal(c(y.hat), convolve(y, rev(wts/sum(wts)), type="open"))

```

ts

*Time-Series Objects***Description**

The function `ts` is used to create time-series objects.

`as.ts` and `is.ts` coerce an object to a time-series and test whether an object is a time series.

**Usage**

```

ts(data = NA, start = 1, end = numeric(), frequency = 1,
   deltat = 1, ts.eps = getOption("ts.eps"),
   class = if(nseries > 1) c("mts", "ts", "matrix", "array") else "ts",
   names = )
as.ts(x, ...)
is.ts(x)

is.mts(x)

```

**Arguments**

|                        |  |
|------------------------|--|
| <code>data</code>      | a vector or matrix of the observed time-series values. A data frame will be coerced to a numeric matrix via <code>data.matrix</code> . (See also ‘Details’.)   |
| <code>start</code>     | the time of the first observation. Either a single number or a vector of two numbers (the second of which is an integer), which specify a natural time unit and a (1-based) number of samples into the time unit. See the examples for the use of the second form. |
| <code>end</code>       | the time of the last observation, specified in the same way as <code>start</code> .  |
| <code>frequency</code> | the number of observations per unit of time.   |
| <code>deltat</code>    | the fraction of the sampling period between successive observations; e.g., 1/12 for monthly data. Only one of <code>frequency</code> or <code>deltat</code> should be provided.  |
| <code>ts.eps</code>    | time series comparison tolerance. Frequencies are considered equal if their absolute difference is less than <code>ts.eps</code> .   |
| <code>class</code>     | class to be given to the result, or none if <code>NULL</code> or <code>"none"</code> . The default is <code>"ts"</code> for a single series, or <code>c("mts", "ts", "matrix", "array")</code> for multiple series.  |
| <code>names</code>     | a character vector of names for the series in a multiple series: defaults to the <code>colnames</code> of <code>data</code> , or <code>"Series 1", "Series 2", ...</code>  |
| <code>x</code>         | an arbitrary R object.   |
| <code>...</code>       | arguments passed to methods (unused for the default method).   |

## Details

The function `ts` is used to create time-series objects. These are vectors or matrices which inherit from class `"ts"` (and have additional attributes) which represent data which has been sampled at equispaced points in time. In the matrix case, each column of the matrix `data` is assumed to contain a single (univariate) time series. Time series must have at least one observation, and although they need not be numeric there is very limited support for non-numeric series.

Class `"ts"` has a number of methods. In particular arithmetic will attempt to align time axes, and subsetting to extract subsets of series can be used (e.g., `EuStockMarkets[, "DAX"]`). However, subsetting the first (or only) dimension will return a matrix or vector, as will matrix subsetting. Subassignment can be used to replace values but not to extend a series (see `window`). There is a method for `t` that transposes the series as a matrix (a one-column matrix if a vector) and hence returns a result that does not inherit from class `"ts"`.

Argument `frequency` indicates the sampling frequency of the time series, with the default value 1 indicating one sample in each unit time interval. For example, one could use a value of 7 for `frequency` when the data are sampled daily, and the natural time period is a week, or 12 when the data are sampled monthly and the natural time period is a year. Values of 4 and 12 are assumed in (e.g.) `print` methods to imply a quarterly and monthly series respectively. `frequency` need not be a whole number: for example, `frequency = 0.2` would imply sampling once every five time units.

`as.ts` is generic. Its default method will use the `tsp` attribute of the object if it has one to set the start and end times and frequency.

`is.ts()` tests if an object is a time series, i.e., inherits from `"ts"` and is of positive length.

`is.mts(x)` tests if an object `x` is a multivariate time series, i.e., fulfills `is.ts(x)`, `is.matrix(x)` and inherits from class `"mts"`.

## See Also

`tsp`, `frequency`, `start`, `end`, `time`, `window`; `print.ts`, the print method for time series objects; `plot.ts`, the plot method for time series objects.

For other definitions of ‘time series’ (e.g., time-ordered observations) see the CRAN task view at <https://CRAN.R-project.org/view=TimeSeries>.

## Examples

```
require(graphics)

ts(1:10, frequency = 4, start = c(1959, 2)) # 2nd Quarter of 1959
print( ts(1:10, frequency = 7, start = c(12, 2)), calendar = TRUE)
# print.ts(.)
## Using July 1954 as start date:
gnp <- ts(cumsum(1 + round(rnorm(100), 2)),
          start = c(1954, 7), frequency = 12)
plot(gnp) # using 'plot.ts' for time-series plot

## Multivariate
z <- ts(matrix(rnorm(300), 100, 3), start = c(1961, 1), frequency = 12)
class(z)
```

```
is.mts(z)
head(z) # as "matrix"
plot(z)
plot(z, plot.type = "single", lty = 1:3)

## A phase plot:
plot(nhtemp, lag(nhtemp, 1), cex = .8, col = "blue",
     main = "Lag plot of New Haven temperatures")
```

---

ts-methods*Methods for Time Series Objects*

---

## Description

Methods for objects of class "ts", typically the result of [ts](#).

## Usage

```
## S3 method for class 'ts'
diff(x, lag = 1, differences = 1, ...)

## S3 method for class 'ts'
na.omit(object, ...)
```

## Arguments

|             |  |
|-------------|--|
| x           | an object of class "ts" containing the values to be differenced. |
| lag         | an integer indicating which lag to use.                          |
| differences | an integer indicating the order of the difference.               |
| object      | a univariate or multivariate time series.                        |
| ...         | further arguments to be passed to or from methods.               |

## Details

The `na.omit` method omits initial and final segments with missing values in one or more of the series. 'Internal' missing values will lead to failure.

## Value

For the `na.omit` method, a time series without missing values. The class of object will be preserved.

## See Also

[diff](#); [na.omit](#), [na.fail](#), [na.contiguous](#).

---

ts.plot

*Plot Multiple Time Series*

---

### Description

Plot several time series on a common plot. Unlike `plot.ts` the series can have a different time bases, but they should have the same frequency.

### Usage

```
ts.plot(..., gpars = list())
```

### Arguments

`...` one or more univariate or multivariate time series.

`gpars` list of named graphics parameters to be passed to the plotting functions. Those commonly used can be supplied directly in `...`

### Value

None.

### Note

Although this can be used for a single time series, `plot` is easier to use and is preferred.

### See Also

[plot.ts](#)

### Examples

```
require(graphics)

ts.plot(ldeaths, mdeaths, fdeaths,
        gpars=list(xlab="year", ylab="deaths", lty=c(1:3)))
```

---

ts.union

*Bind Two or More Time Series*

---

### Description

Bind time series which have a common frequency. `ts.union` pads with NAs to the total time coverage, `ts.intersect` restricts to the time covered by all the series.

### Usage

```
ts.intersect(..., dframe = FALSE)
ts.union(..., dframe = FALSE)
```

**Arguments**

`...` two or more univariate or multivariate time series, or objects which can coerced to time series.

`dframe` logical; if TRUE return the result as a data frame.

**Details**

As a special case, `...` can contain vectors or matrices of the same length as the combined time series of the time series present, as well as those of a single row.

**Value**

A time series object if `dframe` is FALSE, otherwise a data frame.

**See Also**

[cbind](#).

**Examples**

```
ts.union(mdeaths, fdeaths)
cbind(mdeaths, fdeaths) # same as the previous line
ts.intersect(window(mdeaths, 1976), window(fdeaths, 1974, 1978))

sales1 <- ts.union(BJsales, lead = BJsales.lead)
ts.intersect(sales1, lead3 = lag(BJsales.lead, -3))
```

---

tsdiag

*Diagnostic Plots for Time-Series Fits*

---

**Description**

A generic function to plot time-series diagnostics.

**Usage**

```
tsdiag(object, gof.lag, ...)
```

**Arguments**

`object` a fitted time-series model

`gof.lag` the maximum number of lags for a Portmanteau goodness-of-fit test

`...` further arguments to be passed to particular methods

**Details**

This is a generic function. It will generally plot the residuals, often standardized, the autocorrelation function of the residuals, and the p-values of a Portmanteau test for all lags up to `gof.lag`.

The methods for [arima](#) and [StructTS](#) objects plots residuals scaled by the estimate of their (individual) variance, and use the Ljung–Box version of the portmanteau test.

**Value**

None. Diagnostics are plotted.

**See Also**

[arima](#), [StructTS](#), [Box.test](#)

**Examples**

```
require(graphics)

fit <- arima(lh, c(1,0,0))
tsdiag(fit)

## see also examples(arima)

(fit <- StructTS(log10(JohnsonJohnson), type = "BSM"))
tsdiag(fit)
```

---

tsp

*Tsp Attribute of Time-Series-like Objects*

---

**Description**

`tsp` returns the `tsp` attribute (or `NULL`). It is included for compatibility with S version 2. `tsp<-` sets the `tsp` attribute. `hasTsp` ensures `x` has a `tsp` attribute, by adding one if needed.

**Usage**

```
tsp(x)
tsp(x) <- value
hasTsp(x)
```

**Arguments**

`x` a vector or matrix or univariate or multivariate time-series.  
`value` a numeric vector of length 3 or `NULL`.

**Details**

The `tsp` attribute gives the start time *in time units*, the end time and the frequency (the number of observations per unit of time, e.g. 12 for a monthly series).

Assignments are checked for consistency.

Assigning `NULL` which removes the `tsp` attribute *and* any `"ts"` (or `"mts"`) class of `x`.

**Value**

An object which differs from `x` only in the `tsp` attribute (unless `NULL` is assigned).

`hasTsp` adds, if needed, an attribute with a start time and frequency of 1 and end time [NROW](#)(`x`).

[ts](#), [time](#), [start](#).

---

tsSmooth

*Use Fixed-Interval Smoothing on Time Series*

---

## Description

Performs fixed-interval smoothing on a univariate time series via a state-space model. Fixed-interval smoothing gives the best estimate of the state at each time point based on the whole observed series.

## Usage

```
tsSmooth(object, ...)
```

## Arguments

|        |   |
|--------|---|
| object | a time-series fit. Currently only class " <a href="#">StructTS</a> " is supported |
| ...    | possible arguments for future methods.  |

## Value

A time series, with as many dimensions as the state space and results at each time point of the original series. (For seasonal models, only the current seasonal component is returned.)

## Author(s)

B. D. Ripley

## References

Durbin, J. and Koopman, S. J. (2001) *Time Series Analysis by State Space Methods*. Oxford University Press.

---

 Tukey

---

*The Studentized Range Distribution*

---

## Description

Functions of the distribution of the studentized range,  $R/s$ , where  $R$  is the range of a standard normal sample and  $df \times s^2$  is independently distributed as chi-squared with  $df$  degrees of freedom, see [pchisq](#).

## Usage

```
ptukey(q, nmeans, df, nranges = 1, lower.tail = TRUE, log.p = FALSE)
qtukey(p, nmeans, df, nranges = 1, lower.tail = TRUE, log.p = FALSE)
```

## Arguments

|                         |   |
|-------------------------|---|
| <code>q</code>          | vector of quantiles.  |
| <code>p</code>          | vector of probabilities.  |
| <code>nmeans</code>     | sample size for range (same for each group).  |
| <code>df</code>         | degrees of freedom for $s$ (see below).   |
| <code>nranges</code>    | number of <i>groups</i> whose <b>maximum</b> range is considered.                     |
| <code>log.p</code>      | logical; if TRUE, probabilities <code>p</code> are given as $\log(p)$ .               |
| <code>lower.tail</code> | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ . |

## Details

If  $n_g = \text{nranges}$  is greater than one,  $R$  is the *maximum* of  $n_g$  groups of `nmeans` observations each.

## Value

`ptukey` gives the distribution function and `qtukey` its inverse, the quantile function.

The length of the result is the maximum of the lengths of the numerical arguments. The other numerical arguments are recycled to that length. Only the first elements of the logical arguments are used.

## Note

A Legendre 16-point formula is used for the integral of `ptukey`. The computations are relatively expensive, especially for `qtukey` which uses a simple secant method for finding the inverse of `ptukey`. `qtukey` will be accurate to the 4th decimal place.

## Source

`qtukey` is in part adapted from Odeh and Evans (1974).

Examples

```
if(interactive())
  curve(ptukey(x, nm = 6, df = 5), from = -1, to = 8, n = 101)
(ptt <- ptukey(0:10, 2, df = 5))
(qtt <- qtukey(.95, 2, df = 2:11))
## The precision may be not much more than about 8 digits:
summary(abs(.95 - ptukey(qtt, 2, df = 2:11)))
```

---

|          |  |
|----------|--|
| TukeyHSD | Compute Tukey Honest Significant Differences |
|----------|--|

---

Description

Create a set of confidence intervals on the differences between the means of the levels of a factor with the specified family-wise probability of coverage. The intervals are based on the Studentized range statistic, Tukey’s ‘Honest Significant Difference’ method.

Usage

```
TukeyHSD(x, which, ordered = FALSE, conf.level = 0.95, ...)
```

Arguments

|            |  |
|------------|--|
| x          | A fitted model object, usually an <a href="#">aov</a> fit.   |
| which      | A character vector listing terms in the fitted model for which the intervals should be calculated. Defaults to all the terms.  |
| ordered    | A logical value indicating if the levels of the factor should be ordered according to increasing average in the sample before taking differences. If <code>ordered</code> is true then the calculated differences in the means will all be positive. The significant differences will be those for which the <code>lwr</code> end point is positive. |
| conf.level | A numeric value between zero and one giving the family-wise confidence level to use.   |
| ...        | Optional additional arguments. None are used at present.   |

## Details

This is a generic function: the description here applies to the method for fits of class `"aov"`.

When comparing the means for the levels of a factor in an analysis of variance, a simple comparison using t-tests will inflate the probability of declaring a significant difference when it is not in fact present. This because the intervals are calculated with a given coverage probability for each interval but the interpretation of the coverage is usually with respect to the entire family of intervals.

John Tukey introduced intervals based on the range of the sample means rather than the individual differences. The intervals returned by this function are based on this Studentized range statistics.

The intervals constructed in this way would only apply exactly to balanced designs where there are the same number of observations made at each level of the factor. This function incorporates an adjustment for sample size that produces sensible intervals for mildly unbalanced designs.

If `which` specifies non-factor terms these will be dropped with a warning: if no terms are left this is an error.

## Value

A list of class `c("multicomp", "TukeyHSD")`, with one component for each term requested in `which`. Each component is a matrix with columns `diff` giving the difference in the observed means, `lwr` giving the lower end point of the interval, `upr` giving the upper end point and `p.adj` giving the p-value after adjustment for the multiple comparisons.

There are `print` and `plot` methods for class `"TukeyHSD"`. The `plot` method does not accept `xlab`, `ylab` or `main` arguments and creates its own values for each plot.

## See Also

[aov](#), [qtukey](#), [model.tables](#), [glht](#) in package **multcomp**.

## Examples

```
require(graphics)

summary(fml <- aov(breaks ~ wool + tension, data = warpbreaks))
TukeyHSD(fml, "tension", ordered = TRUE)
plot(TukeyHSD(fml, "tension"))
```

**Description**

These functions provide information about the uniform distribution on the interval from `min` to `max`. `dunif` gives the density, `punif` gives the distribution function `qunif` gives the quantile function and `runif` generates random deviates.

**Usage**

```
dunif(x, min = 0, max = 1, log = FALSE)
punif(q, min = 0, max = 1, lower.tail = TRUE, log.p = FALSE)
qunif(p, min = 0, max = 1, lower.tail = TRUE, log.p = FALSE)
runif(n, min = 0, max = 1)
```

**Arguments**

|                         |   |
|-------------------------|---|
| <code>x, q</code>       | vector of quantiles.  |
| <code>p</code>          | vector of probabilities.  |
| <code>n</code>          | number of observations. If <code>length(n) &gt; 1</code> , the length is taken to be the number required. |
| <code>min, max</code>   | lower and upper limits of the distribution. Must be finite.   |
| <code>log, log.p</code> | logical; if TRUE, probabilities <code>p</code> are given as <code>log(p)</code> .                         |
| <code>lower.tail</code> | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                     |

**Details**

If `min` or `max` are not specified they assume the default values of 0 and 1 respectively.

The uniform distribution has density

$$f(x) = \frac{1}{\max - \min}$$

for  $\min \leq x \leq \max$ .

For the case of  $u := \min == \max$ , the limit case of  $X \equiv u$  is assumed, although there is no density in that case and `dunif` will return NaN (the error condition).

`runif` will not generate either of the extreme values unless `max = min` or `max - min` is small compared to `min`, and in particular not for the default arguments.

**Value**

`dunif` gives the density, `punif` gives the distribution function, `qunif` gives the quantile function, and `runif` generates random deviates.

The length of the result is determined by `n` for `runif`, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than `n` are recycled to the length of the result. Only the first elements of the logical arguments are used.

**Note**

The characteristics of output from pseudo-random number generators (such as precision and periodicity) vary widely. See [.Random.seed](#) for more information on R's random number generation algorithms.

**References**

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

**See Also**

[RNG](#) about random number generation in R.  
[Distributions](#) for other standard distributions.

**Examples**

```
u <- runif(20)

## The following relations always hold :
punif(u) == u
dunif(u) == 1

var(runif(10000))  #- ~ = 1/12 = .08333
```

---

uniroot

---

*One Dimensional Root (Zero) Finding*

---

**Description**

The function `uniroot` searches the interval from `lower` to `upper` for a root (i.e., zero) of the function `f` with respect to its first argument.

Setting `extendInt` to a non-"no" string, means searching for the correct `interval = c(lower, upper)` if `sign(f(x))` does not satisfy the requirements at the interval end points; see the 'Details' section.

**Usage**

```
uniroot(f, interval, ...,
        lower = min(interval), upper = max(interval),
        f.lower = f(lower, ...), f.upper = f(upper, ...),
        extendInt = c("no", "yes", "downX", "upX"), check.conv = FALSE,
        tol = .Machine$double.eps^0.25, maxiter = 1000, trace = 0)
```

**Arguments**

|                           |   |
|---------------------------|---|
| <code>f</code>            | the function for which the root is sought.                                      |
| <code>interval</code>     | a vector containing the end-points of the interval to be searched for the root. |
| <code>...</code>          | additional named or unnamed arguments to be passed to <code>f</code>            |
| <code>lower, upper</code> | the lower and upper end points of the interval to be searched.                  |

|                               |  |
|-------------------------------|--|
| <code>f.lower, f.upper</code> | the same as <code>f(upper)</code> and <code>f(lower)</code> , respectively. Passing these values from the caller where they are often known is more economical as soon as <code>f()</code> contains non-trivial computations.  |
| <code>extendInt</code>        | character string specifying if the interval <code>c(lower, upper)</code> should be extended or directly produce an error when <code>f()</code> does not have differing signs at the endpoints. The default, "no", keeps the search interval and hence produces an error. Can be abbreviated. |
| <code>check.conv</code>       | logical indicating whether a convergence warning of the underlying <code>uniroot</code> should be caught as an error and if non-convergence in <code>maxiter</code> iterations should be an error instead of a warning.  |
| <code>tol</code>              | the desired accuracy (convergence tolerance).  |
| <code>maxiter</code>          | the maximum number of iterations.  |
| <code>trace</code>            | integer number; if positive, tracing information is produced. Higher values giving more details.   |

## Details

Note that arguments after `...` must be matched exactly.

Either `interval` or both `lower` and `upper` must be specified: the upper endpoint must be strictly larger than the lower endpoint. The function values at the endpoints must be of opposite signs (or zero), for `extendInt="no"`, the default. Otherwise, if `extendInt="yes"`, the interval is extended on both sides, in search of a sign change, i.e., until the search interval  $[l, u]$  satisfies  $f(l) \cdot f(u) \leq 0$ .

If it is *known how*  $f$  changes sign at the root  $x_0$ , that is, if the function is increasing or decreasing there, `extendInt` can (and typically should) be specified as "upX" (for "upward crossing") or "downX", respectively. Equivalently, define  $S := \pm 1$ , to require  $S = \text{sign}(f(x_0 + \epsilon))$  at the solution. In that case, the search interval  $[l, u]$  possibly is extended to be such that  $S \cdot f(l) \leq 0$  and  $S \cdot f(u) \geq 0$ .

`uniroot()` uses Fortran subroutine `zeroin` (from Netlib) based on algorithms given in the reference below. They assume a continuous function (which then is known to have at least one root in the interval).

Convergence is declared either if  $f(x) == 0$  or the change in  $x$  for one step of the algorithm is less than `tol` (plus an allowance for representation error in  $x$ ).

If the algorithm does not converge in `maxiter` steps, a warning is printed and the current approximation is returned.

`f` will be called as `f(x, ...)` for a numeric value of  $x$ .

The argument passed to `f` has special semantics and used to be shared between calls. The function should not copy it.

## Value

A list with at least five components: `root` and `f.root` give the location of the root and the value of the function evaluated at that point. `iter` and `estim.prec` give the number of iterations used and an approximate estimated precision for `root`. (If the root occurs at one of the endpoints, the estimated precision is NA.) `init.it` contains the number of *initial* `extendInt` iterations if there were any and is NA otherwise. In the case of such `extendInt` iterations, `iter` contains the sum of these and the `zeroin` iterations.

Further components may be added in the future.

## Source

Based on 'zeroin.c' in <https://netlib.org/c/brent.shar>.

## See Also

[polyroot](#) for all complex roots of a polynomial; [optimize](#), [nlm](#).

## Examples

```
require(utils) # for str

## some platforms hit zero exactly on the first step:
## if so the estimated precision is 2/3.
f <- function (x, a) x - a
str(xmin <- uniroot(f, c(0, 1), tol = 0.0001, a = 1/3))

## handheld calculator example: fixed point of cos(.):
uniroot(function(x) cos(x) - x, lower = -pi, upper = pi, tol = 1e-9)$root

str(uniroot(function(x) x*(x^2-1) + .5, lower = -2, upper = 2,
               tol = 0.0001))
str(uniroot(function(x) x*(x^2-1) + .5, lower = -2, upper = 2,
               tol = 1e-10))

## Find the smallest value x for which exp(x) > 0 (numerically):
r <- uniroot(function(x) 1e80*exp(x) - 1e-300, c(-1000, 0), tol = 1e-15)
str(r, digits.d = 15) # around -745, depending on the platform.

exp(r$root)      # = 0, but not for r$root * 0.999...
minexp <- r$root * (1 - 10*.Machine$double.eps)
exp(minexp)      # typically denormalized

##--- uniroot() with new interval extension + checking features: -----

f1 <- function(x) (121 - x^2)/(x^2+1)
f2 <- function(x) exp(-x)*(x - 12)

try(uniroot(f1, c(0,10)))
try(uniroot(f2, c(0, 2)))
##--> error: f() .. end points not of opposite sign

## where as 'extendInt="yes"' simply first enlarges the search interval:
u1 <- uniroot(f1, c(0,10),extendInt="yes", trace=1)
u2 <- uniroot(f2, c(0,2), extendInt="yes", trace=2)
stopifnot(all.equal(u1$root, 11, tolerance = 1e-5),
          all.equal(u2$root, 12, tolerance = 6e-6))

## The *danger* of interval extension:
## No way to find a zero of a positive function, but
## numerically, f(-|M|) becomes zero :
```

```

u3 <- uniroot(exp, c(0,2), extendInt="yes", trace=TRUE)

## Nonsense example (must give an error):
tools::assertCondition( uniroot(function(x) 1, 0:1, extendInt="yes"),
                        "error", verbose=TRUE)

## Convergence checking :
sinc <- function(x) ifelse(x == 0, 1, sin(x)/x)
curve(sinc, -6,18); abline(h=0,v=0, lty=3, col=adjustcolor("gray", 0.8))

uniroot(sinc, c(0,5), extendInt="yes", maxiter=4) #-> "just" a warning

## now with check.conv=TRUE, must signal a convergence error :

uniroot(sinc, c(0,5), extendInt="yes", maxiter=4, check.conv=TRUE)

### Weibull cumulative hazard (example origin, Ravi Varadhan):
cumhaz <- function(t, a, b) b * (t/b)^a
froot <- function(x, u, a, b) cumhaz(x, a, b) - u

n <- 1000
u <- -log(runif(n))
a <- 1/2
b <- 1
## Find failure times
ru <- sapply(u, function(x)
  uniroot(froot, u=x, a=a, b=b, interval= c(1.e-14, 1e04),
    extendInt="yes")$root)
ru2 <- sapply(u, function(x)
  uniroot(froot, u=x, a=a, b=b, interval= c(0.01, 10),
    extendInt="yes")$root)
stopifnot(all.equal(ru, ru2, tolerance = 6e-6))

r1 <- uniroot(froot, u= 0.99, a=a, b=b, interval= c(0.01, 10),
  extendInt="up")
stopifnot(all.equal(0.99, cumhaz(r1$root, a=a, b=b)))

## An error if 'extendInt' assumes "wrong zero-crossing direction":

uniroot(froot, u= 0.99, a=a, b=b, interval= c(0.1, 10), extendInt="down")

```

---

update

---

*Update and Re-fit a Model Call*

---

## Description

update will update and (by default) re-fit a model. It does this by extracting the call stored in the object, updating the call and (by default) evaluating that call. Sometimes it is useful to call update with only one argument, for example if the data frame has been corrected.

“Extracting the call” in update() and similar functions uses getCall() which itself is a (S3) generic function with a default method that simply gets x\$call.

Because of this, `update()` will often work (via its default method) on new model classes, either automatically, or by providing a simple `getCall()` method for that class.

### Usage

```
update(object, ...)
## Default S3 method:
update(object, formula., ..., evaluate = TRUE)

getCall(x, ...)
```

### Arguments

|                        |   |
|------------------------|---|
| <code>object, x</code> | An existing fit from a model function such as <code>lm</code> , <code>glm</code> and many others.                             |
| <code>formula.</code>  | Changes to the formula – see <code>update.formula</code> for details.   |
| <code>...</code>       | Additional arguments to the call, or arguments with changed values. Use <code>name = NULL</code> to remove the argument name. |
| <code>evaluate</code>  | If true evaluate the new call else return the call.   |

### Value

If `evaluate = TRUE` the fitted object, otherwise the updated call.

update(lm.D9)
getCall(lm.D90) # "through the origin"

options(oldcon)
```

---

|                |                       |
|----------------|-----------------------|
| update.formula | <i>Model Updating</i> |
|----------------|-----------------------|

---

## Description

`update.formula` is used to update model formulae. This typically involves adding or dropping terms, but updates can be more general.

## Usage

```
## S3 method for class 'formula'
update(old, new, ...)
```

## Arguments

|                  |  |
|------------------|--|
| <code>old</code> | a model formula to be updated.                             |
| <code>new</code> | a formula giving a template which specifies how to update. |
| <code>...</code> | further arguments passed to or from other methods.         |

## Details

Either or both of `old` and `new` can be objects such as length-one character vectors which can be coerced to a formula via [as.formula](#).

The function works by first identifying the *left-hand side* and *right-hand side* of the `old` formula. It then examines the `new` formula and substitutes the *lhs* of the `old` formula for any occurrence of `'.'` on the left of `new`, and substitutes the *rhs* of the `old` formula for any occurrence of `'.'` on the right of `new`. The result is then simplified via [terms.formula](#) (`simplify = TRUE`).

## Value

The updated formula is returned. The environment of the result is that of `old`.

## See Also

[terms](#), [model.matrix](#).

## Examples

```
update(y ~ x,      ~ . + x2) #> y ~ x + x2
update(y ~ x, log(.) ~ . ) #> log(y) ~ x
update(. ~ u+v, res ~ . ) #> res ~ u + v
```

var.test

*F Test to Compare Two Variances***Description**

Performs an F test to compare the variances of two samples from normal populations.

**Usage**

```
var.test(x, ...)

## Default S3 method:
var.test(x, y, ratio = 1,
         alternative = c("two.sided", "less", "greater"),
         conf.level = 0.95, ...)

## S3 method for class 'formula'
var.test(formula, data, subset, na.action, ...)
```

**Arguments**

|                          |  |
|--------------------------|--|
| <code>x, y</code>        | numeric vectors of data values, or fitted linear model objects (inheriting from class "lm").   |
| <code>ratio</code>       | the hypothesized ratio of the population variances of <code>x</code> and <code>y</code> .  |
| <code>alternative</code> | a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.  |
| <code>conf.level</code>  | confidence level for the returned confidence interval.   |
| <code>formula</code>     | a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> is a numeric variable giving the data values and <code>rhs</code> a factor with two levels giving the corresponding groups.                            |
| <code>data</code>        | an optional matrix or data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> . |
| <code>subset</code>      | an optional vector specifying a subset of observations to be used.   |
| <code>na.action</code>   | a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .   |
| <code>...</code>         | further arguments to be passed to or from methods.   |

**Details**

The null hypothesis is that the ratio of the variances of the populations from which `x` and `y` were drawn, or in the data to which the linear models `x` and `y` were fitted, is equal to `ratio`.

**Value**

A list with class "htest" containing the following components:

|                        |   |
|------------------------|---|
| <code>statistic</code> | the value of the F test statistic.                                      |
| <code>parameter</code> | the degrees of the freedom of the F distribution of the test statistic. |

|                          |  |
|--------------------------|--|
| <code>p.value</code>     | the p-value of the test.   |
| <code>conf.int</code>    | a confidence interval for the ratio of the population variances.         |
| <code>estimate</code>    | the ratio of the sample variances of <code>x</code> and <code>y</code> . |
| <code>null.value</code>  | the ratio of population variances under the null.                        |
| <code>alternative</code> | a character string describing the alternative hypothesis.                |
| <code>method</code>      | the character string "F test to compare two variances".                  |
| <code>data.name</code>   | a character string giving the names of the data.                         |

### See Also

[bartlett.test](#) for testing homogeneity of variances in more than two samples from normal distributions; [ansari.test](#) and [mood.test](#) for two rank based (nonparametric) two-sample tests for difference in scale.

### Examples

```
x <- rnorm(50, mean = 0, sd = 2)
y <- rnorm(30, mean = 1, sd = 1)
var.test(x, y) # Do x and y have the same variance?
var.test(lm(x ~ 1), lm(y ~ 1)) # The same.
```

---

|         |   |
|---------|---|
| varimax | <i>Rotation Methods for Factor Analysis</i> |
|---------|---|

---

### Description

These functions ‘rotate’ loading matrices in factor analysis.

### Usage

```
varimax(x, normalize = TRUE, eps = 1e-5)
promax(x, m = 4)
```

### Arguments

|                        |   |
|------------------------|---|
| <code>x</code>         | A loadings matrix, with $p$ rows and $k < p$ columns  |
| <code>m</code>         | The power used the target for <code>promax</code> . Values of 2 to 4 are recommended.   |
| <code>normalize</code> | logical. Should Kaiser normalization be performed? If so the rows of <code>x</code> are re-scaled to unit length before rotation, and scaled back afterwards. |
| <code>eps</code>       | The tolerance for stopping: the relative change in the sum of singular values.  |

### Details

These seek a ‘rotation’ of the factors  $x \%*\% T$  that aims to clarify the structure of the loadings matrix. The matrix  $T$  is a rotation (possibly with reflection) for `varimax`, but a general linear transformation for `promax`, with the variance of the factors being preserved.

**Value**

A list with components

loadings      The ‘rotated’ loadings matrix,  $x \%*\% \text{rotmat}$ , of class "loadings".  
 rotmat        The ‘rotation’ matrix.

varimax(loadings(fa), normalize = FALSE)
promax(loadings(fa))
```

---

 vcov

---

*Calculate Variance-Covariance Matrix for a Fitted Model Object*

---

**Description**

Returns the variance-covariance matrix of the main parameters of a fitted model object. The “main” parameters of model correspond to those returned by `coef`, and typically do not contain a nuisance scale parameter (`sigma`).

**Usage**

```
vcov(object, ...)
## S3 method for class 'lm'
vcov(object, complete = TRUE, ...)
## and also for '[summary.]glm' and 'mlm'
## S3 method for class 'aov'
vcov(object, complete = FALSE, ...)

.vcov.aliased.aliased, vc, complete = TRUE)
```

**Arguments**

|                       |   |
|-----------------------|---|
| <code>object</code>   | a fitted model object, typically. Sometimes also a <code>summary()</code> object of such a fitted model.  |
| <code>complete</code> | for the <code>aov</code> , <code>lm</code> , <code>glm</code> , <code>mlm</code> , and where applicable <code>summary.lm</code> etc methods: logical indicating if the full variance-covariance matrix should be returned also in case of an over-determined system where some coefficients are undefined and <code>coef(.)</code> contains NAs correspondingly. When <code>complete = TRUE</code> , <code>vcov()</code> is compatible with <code>coef()</code> also in this singular case. |
| <code>...</code>      | additional arguments for method functions. For the <code>glm</code> method this can be used to pass a <code>dispersion</code> parameter.  |
| <code>aliased</code>  | a <b>logical</b> vector typically identical to <code>is.na(coef(.))</code> indicating which coefficients are ‘aliased’.   |
| <code>vc</code>       | a variance-covariance matrix, typically “incomplete”, i.e., with no rows and columns for aliased coefficients.  |

**Details**

`vcov()` is a generic function and functions with names beginning in `vcov.` will be methods for this function. Classes with methods for this function include: `lm`, `mlm`, `glm`, `nls`, `summary.lm`, `summary.glm`, `negbin`, `polr`, `rlm` (in package **MASS**), `multinom` (in package **nnet**) `gls`, `lme` (in package **nlme**), `coxph` and `survreg` (in package **survival**).

(`vcov()` methods for summary objects allow more efficient and still encapsulated access when both `summary(mod)` and `vcov(mod)` are needed.)

`.vcov.aliased()` is an auxiliary function useful for `vcov` method implementations which have to deal with singular model fits encoded via NA coefficients: It augments a `vcov`-matrix `vc` by NA rows and columns where needed, i.e., when some entries of `aliased` are true and `vc` is of smaller dimension than `length(aliased)`.

**Value**

A matrix of the estimated covariances between the parameter estimates in the linear or non-linear predictor of the model. This should have row and column names corresponding to the parameter names given by the `coef` method.

When some coefficients of the (linear) model are undetermined and hence NA because of linearly dependent terms (or an “over specified” model), also called “aliased”, see `alias`, then since R version 3.5.0, `vcov()` (iff `complete = TRUE`, i.e., by default for `lm` etc, but not for `aov`) contains corresponding rows and columns of NAs, wherever `coef()` has always contained such NAs.

**Description**

Density, distribution function, quantile function and random generation for the Weibull distribution with parameters `shape` and `scale`.

**Usage**

```
dweibull(x, shape, scale = 1, log = FALSE)
pweibull(q, shape, scale = 1, lower.tail = TRUE, log.p = FALSE)
qweibull(p, shape, scale = 1, lower.tail = TRUE, log.p = FALSE)
rweibull(n, shape, scale = 1)
```

**Arguments**

`x, q` vector of quantiles.  
`p` vector of probabilities.  
`n` number of observations. If `length(n) > 1`, the length is taken to be the number required.  
`shape, scale` shape and scale parameters, the latter defaulting to 1.  
`log, log.p` logical; if TRUE, probabilities `p` are given as `log(p)`.  
`lower.tail` logical; if TRUE (default), probabilities are  $P[X \leq x]$ , otherwise,  $P[X > x]$ .

**Details**

The Weibull distribution with `shape` parameter  $a$  and `scale` parameter  $\sigma$  has density given by

$$f(x) = (a/\sigma)(x/\sigma)^{a-1} \exp(-(x/\sigma)^a)$$

for  $x > 0$ . The cumulative distribution function is  $F(x) = 1 - \exp(-(x/\sigma)^a)$  on  $x > 0$ , the mean is  $E(X) = \sigma\Gamma(1 + 1/a)$ , and the  $Var(X) = \sigma^2(\Gamma(1 + 2/a) - (\Gamma(1 + 1/a))^2)$ .

**Value**

`dweibull` gives the density, `pweibull` gives the distribution function, `qweibull` gives the quantile function, and `rweibull` generates random deviates.

Invalid arguments will result in return value NaN, with a warning.

The length of the result is determined by `n` for `rweibull`, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than `n` are recycled to the length of the result. Only the first elements of the logical arguments are used.

**Note**

The cumulative hazard  $H(t) = -\log(1 - F(t))$  is

```
-pweibull(t, a, b, lower = FALSE, log = TRUE)
```

which is just  $H(t) = (t/b)^a$ .

**Source**

`[dpq]weibull` are calculated directly from the definitions. `rweibull` uses inversion.

**See Also**

[Distributions](#) for other standard distributions, including the [Exponential](#) which is a special case of the Weibull distribution.

**Examples**

```
x <- c(0, rlnorm(50))
all.equal(dweibull(x, shape = 1), dexp(x))
all.equal(pweibull(x, shape = 1, scale = pi), pexp(x, rate = 1/pi))
## Cumulative hazard H():
all.equal(pweibull(x, 2.5, pi, lower.tail = FALSE, log.p = TRUE),
          -(x/pi)^2.5, tolerance = 1e-15)
all.equal(qweibull(x/11, shape = 1, scale = pi), qexp(x/11, rate = 1/pi))
```

---

|               |                                 |
|---------------|---------------------------------|
| weighted.mean | <i>Weighted Arithmetic Mean</i> |
|---------------|---------------------------------|

---

**Description**

Compute a weighted mean.

**Usage**

```
weighted.mean(x, w, ...)

## Default S3 method:
weighted.mean(x, w, ..., na.rm = FALSE)
```

**Arguments**

|                    |  |
|--------------------|--|
| <code>x</code>     | an object containing the values whose weighted mean is to be computed.   |
| <code>w</code>     | a numerical vector of weights the same length as <code>x</code> giving the weights to use for elements of <code>x</code> . |
| <code>...</code>   | arguments to be passed to or from methods.   |
| <code>na.rm</code> | a logical value indicating whether NA values in <code>x</code> should be stripped before the computation proceeds.         |

**Details**

This is a generic function and methods can be defined for the first argument `x`: apart from the default methods there are methods for the date-time classes "POSIXct", "POSIXlt", "difftime" and "Date". The default method will work for any numeric-like object for which `[]`, multiplication, division and [sum](#) have suitable methods, including complex vectors.

If `w` is missing then all elements of `x` are given the same weight, otherwise the weights are normalized to sum to one (if possible: if their sum is zero or infinite the value is likely to be NaN).

Missing values in `w` are not handled specially and so give a missing value as the result. However, zero weights *are* handled specially and the corresponding `x` values are omitted from the sum.

**Value**

For the default method, a length-one numeric vector.

**See Also**[mean](#)**Examples**

```
## GPA from Siegel 1994
wt <- c(5, 5, 4, 1)/15
x <- c(3.7, 3.3, 3.5, 2.8)
xm <- weighted.mean(x, wt)
```

---

weighted.residuals *Compute Weighted Residuals*

---

**Description**

Computed weighted residuals from a linear model fit.

**Usage**

```
weighted.residuals(obj, drop0 = TRUE)
```

**Arguments**

`obj`                    R object, typically of class [lm](#) or [glm](#).  
`drop0`                logical. If TRUE, drop all cases with `weights == 0`.

**Details**

Weighted residuals are based on the deviance residuals, which for a [lm](#) fit are the raw residuals  $R_i$  multiplied by  $\sqrt{w_i}$ , where  $w_i$  are the `weights` as specified in [lm](#)'s call.

Dropping cases with weights zero is compatible with [influence](#) and related functions.

**Value**

Numeric vector of length  $n'$ , where  $n'$  is the number of non-0 weights (`drop0 = TRUE`) or the number of observations, otherwise.

**See Also**

[residuals](#), [lm.influence](#), etc.

**Examples**

```
## following on from example(lm)

all.equal(weighted.residuals(lm.D9),
          residuals(lm.D9))

x <- 1:10
w <- 0:9
y <- rnorm(x)
weighted.residuals(lmxy <- lm(y ~ x, weights = w))
weighted.residuals(lmxy, drop0 = FALSE)
```

---

|         |                              |
|---------|------------------------------|
| weights | <i>Extract Model Weights</i> |
|---------|------------------------------|

---

### Description

`weights` is a generic function which extracts fitting weights from objects returned by modeling functions.

Methods can make use of `napredict` methods to compensate for the omission of missing values. The default methods does so.

### Usage

```
weights(object, ...)
```

### Arguments

|                     |  |
|---------------------|--|
| <code>object</code> | an object for which the extraction of model weights is meaningful. |
| <code>...</code>    | other arguments passed to methods.                                 |

### Value

Weights extracted from the object `object`: the default method looks for component "weights" and if not NULL calls `napredict` on it.

### References

Chambers, J. M. and Hastie, T. J. (1992) *Statistical Models in S*. Wadsworth & Brooks/Cole.

|                          |  |
|--------------------------|--|
| <code>wilcox.test</code> | <i>Wilcoxon Rank Sum and Signed Rank Tests</i> |
|--------------------------|--|

---

### Description

Performs one- and two-sample Wilcoxon tests on vectors of data; the latter is also known as ‘Mann-Whitney’ test.

### Usage

```
wilcox.test(x, ...)

## Default S3 method:
wilcox.test(x, y = NULL,
            alternative = c("two.sided", "less", "greater"),
            mu = 0, paired = FALSE, exact = NULL, correct = TRUE,
            conf.int = FALSE, conf.level = 0.95,
```

```

        tol.root = 1e-4, digits.rank = Inf, ...)

## S3 method for class 'formula'
wilcox.test(formula, data, subset, na.action = na.pass, ...)

```

### Arguments

|                          |  |
|--------------------------|--|
| <code>x</code>           | numeric vector of data values. Non-finite (e.g., infinite or missing) values will be omitted.  |
| <code>y</code>           | an optional numeric vector of data values: as with <code>x</code> non-finite values will be omitted.   |
| <code>alternative</code> | a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.  |
| <code>mu</code>          | a number specifying an optional parameter used to form the null hypothesis. See 'Details'.   |
| <code>paired</code>      | a logical indicating whether you want a paired test.   |
| <code>exact</code>       | a logical indicating whether an exact p-value should be computed.  |
| <code>correct</code>     | a logical indicating whether to apply continuity correction in the normal approximation for the p-value.   |
| <code>conf.int</code>    | a logical indicating whether a confidence interval should be computed.   |
| <code>conf.level</code>  | confidence level of the interval.  |
| <code>tol.root</code>    | (when <code>conf.int</code> is true:) a positive numeric tolerance, used in <code>uniroot</code> (*, tol=tol.root) calls.  |
| <code>digits.rank</code> | a number; if finite, <code>rank(signif(r, digits.rank))</code> will be used to compute ranks for the test statistic instead of (the default) <code>rank(r)</code> .  |
| <code>formula</code>     | a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> is a numeric variable giving the data values and <code>rhs</code> either 1 for a one-sample or paired test or a factor with two levels giving the corresponding groups. If <code>lhs</code> is of class "Pair" and <code>rhs</code> is 1, a paired test is done, see Examples. |
| <code>data</code>        | an optional matrix or data frame (or similar: see <code>model.frame</code> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .  |
| <code>subset</code>      | an optional vector specifying a subset of observations to be used.   |
| <code>na.action</code>   | a function which indicates what should happen when the data contain NAs.   |
| <code>...</code>         | further arguments to be passed to or from methods. For the <code>formula</code> method, this includes arguments of the default method, but not <code>paired</code> .   |

### Details

The formula interface is only applicable for the 2-sample tests.

If only `x` is given, or if both `x` and `y` are given and `paired` is TRUE, a Wilcoxon signed rank test of the null that the distribution of `x` (in the one sample case) or of `x - y` (in the paired two sample case) is symmetric about `mu` is performed.

Otherwise, if both `x` and `y` are given and `paired` is FALSE, a Wilcoxon rank sum test (equivalent to the Mann-Whitney test: see the Note) is carried out. In this case, the null hypothesis is that the distributions of `x` and `y` differ by a location shift of `mu` and the alternative is that they differ by some other location shift (and the one-sided alternative "greater" is that `x` is shifted to the right of `y`).

By default (if `exact` is not specified), an exact p-value is computed if the samples contain less than 50 finite values and there are no ties. Otherwise, a normal approximation is used.

For stability reasons, it may be advisable to use rounded data or to set `digits.rank = 7`, say, such that determination of ties does not depend on very small numeric differences (see the example).

Optionally (if argument `conf.int` is true), a nonparametric confidence interval and an estimator for the pseudomedian (one-sample case) or for the difference of the location parameters  $x - y$  is computed. (The pseudomedian of a distribution  $F$  is the median of the distribution of  $(u + v)/2$ , where  $u$  and  $v$  are independent, each with distribution  $F$ . If  $F$  is symmetric, then the pseudomedian and median coincide. See Hollander & Wolfe (1973), page 34.) Note that in the two-sample case the estimator for the difference in location parameters does **not** estimate the difference in medians (a common misconception) but rather the median of the difference between a sample from  $x$  and a sample from  $y$ .

If exact p-values are available, an exact confidence interval is obtained by the algorithm described in Bauer (1972), and the Hodges-Lehmann estimator is employed. Otherwise, the returned confidence interval and point estimate are based on normal approximations. These are continuity-corrected for the interval but *not* the estimate (as the correction depends on the `alternative`).

With small samples it may not be possible to achieve very high confidence interval coverages. If this happens a warning will be given and an interval with lower coverage will be substituted.

When  $x$  (and  $y$  if applicable) are valid, the function now always returns, also in the `conf.int = TRUE` case when a confidence interval cannot be computed, in which case the interval boundaries and sometimes the `estimate` now contain `NaN`.

### Value

A list with class `"htest"` containing the following components:

|                          |   |
|--------------------------|---|
| <code>statistic</code>   | the value of the test statistic with a name describing it.  |
| <code>parameter</code>   | the parameter(s) for the exact distribution of the test statistic.  |
| <code>p.value</code>     | the p-value for the test.   |
| <code>null.value</code>  | the location parameter $\mu$ .  |
| <code>alternative</code> | a character string describing the alternative hypothesis.   |
| <code>method</code>      | the type of test applied.   |
| <code>data.name</code>   | a character string giving the names of the data.  |
| <code>conf.int</code>    | a confidence interval for the location parameter. (Only present if argument <code>conf.int = TRUE</code> .) |
| <code>estimate</code>    | an estimate of the location parameter. (Only present if argument <code>conf.int = TRUE</code> .)            |

### Warning

This function can use large amounts of memory and stack (and even crash R if the stack limit is exceeded) if `exact = TRUE` and one sample is large (several thousands or more).

### Note

The literature is not unanimous about the definitions of the Wilcoxon rank sum and Mann-Whitney tests. The two most common definitions correspond to the sum of the ranks of the first sample with the minimum value  $(m(m + 1))/2$  for a first sample of size  $m$  subtracted or not: R subtracts. It seems Wilcoxon's original paper used the unadjusted sum of the ranks but subsequent tables subtracted the minimum.

```
wilcox.test(rnorm(10), rnorm(10, 2), conf.int = TRUE)

## Formula interface.
boxplot(Ozone ~ Month, data = airquality)
wilcox.test(Ozone ~ Month, data = airquality,
            subset = Month %in% c(5, 8))

## accuracy in ties determination via 'digits.rank':
wilcox.test( 4:2,      3:1,      paired=TRUE) # Warning: cannot compute exact p-value with ties
wilcox.test((4:2)/10, (3:1)/10, paired=TRUE) # no ties => *no* warning
wilcox.test((4:2)/10, (3:1)/10, paired=TRUE, digits.rank = 9) # same ties as (4:2, 3:1)
```

---

Wilcoxon

---

*Distribution of the Wilcoxon Rank Sum Statistic*

---

## Description

Density, distribution function, quantile function and random generation for the distribution of the Wilcoxon rank sum statistic obtained from samples with size  $m$  and  $n$ , respectively.

## Usage

```
dwilcox(x, m, n, log = FALSE)
pwilcox(q, m, n, lower.tail = TRUE, log.p = FALSE)
qwilcox(p, m, n, lower.tail = TRUE, log.p = FALSE)
rwilcox(nn, m, n)
```

## Arguments

|                         |  |
|-------------------------|--|
| <code>x, q</code>       | vector of quantiles.   |
| <code>p</code>          | vector of probabilities.   |
| <code>nn</code>         | number of observations. If <code>length(nn) &gt; 1</code> , the length is taken to be the number required. |
| <code>m, n</code>       | numbers of observations in the first and second sample, respectively. Can be vectors of positive integers. |
| <code>log, log.p</code> | logical; if TRUE, probabilities <code>p</code> are given as $\log(p)$ .                                    |
| <code>lower.tail</code> | logical; if TRUE (default), probabilities are $P[X \leq x]$ , otherwise, $P[X > x]$ .                      |

## Details

This distribution is obtained as follows. Let  $x$  and  $y$  be two random, independent samples of size  $m$  and  $n$ . Then the Wilcoxon rank sum statistic is the number of all pairs  $(x[i], y[j])$  for which  $y[j]$  is not greater than  $x[i]$ . This statistic takes values between 0 and  $m * n$ , and its mean and variance are  $m * n / 2$  and  $m * n * (m + n + 1) / 12$ , respectively.

If any of the first three arguments are vectors, the recycling rule is used to do the calculations for all combinations of the three up to the length of the longest vector.

**Value**

`dwilcox` gives the density, `pwilcox` gives the distribution function, `qwilcox` gives the quantile function, and `rwilcox` generates random deviates.

The length of the result is determined by `nn` for `rwilcox`, and is the maximum of the lengths of the numerical arguments for the other functions.

The numerical arguments other than `nn` are recycled to the length of the result. Only the first elements of the logical arguments are used.

**Warning**

These functions can use large amounts of memory and stack (and even crash R if the stack limit is exceeded and stack-checking is not in place) if one sample is large (several thousands or more).

**Note**

S-PLUS used a different (but equivalent) definition of the Wilcoxon statistic: see `wilcox.test` for details.

**Author(s)**

Kurt Hornik

**Source**

These ("d","p","q") are calculated via recursion, based on `cwilcox(k, m, n)`, the number of choices with statistic `k` from samples of size `m` and `n`, which is itself calculated recursively and the results cached. Then `dwilcox` and `pwilcox` sum appropriate values of `cwilcox`, and `qwilcox` is based on inversion.

`rwilcox` generates a random permutation of ranks and evaluates the statistic. Note that it is based on the same C code as `sample()`, and hence is determined by `.Random.seed`, notably from `RNGkind(sample.kind = .)` which changed with R version 3.6.0.

**See Also**

`wilcox.test` to calculate the statistic from data, find p values and so on.

**Distributions** for standard distributions, including `dsignrank` for the distribution of the *one-sample* Wilcoxon signed rank statistic.

**Examples**

```
require(graphics)

x <- -1:(4*6 + 1)
fx <- dwilcox(x, 4, 6)
Fx <- pwilcox(x, 4, 6)

layout(rbind(1,2), widths = 1, heights = c(3,2))
plot(x, fx, type = "h", col = "violet",
     main = "Probabilities (density) of Wilcoxon-Statist.(n=6, m=4)")
plot(x, Fx, type = "s", col = "blue",
     main = "Distribution of Wilcoxon-Statist.(n=6, m=4)")
abline(h = 0:1, col = "gray20", lty = 2)
layout(1) # set back
```

```

N <- 200
hist(U <- rwilcox(N, m = 4, n = 6), breaks = 0:25 - 1/2,
     border = "red", col = "pink", sub = paste("N =", N))
mtext("N * f(x), f() = true \"density\"", side = 3, col = "blue")
lines(x, N*fx, type = "h", col = "blue", lwd = 2)
points(x, N*fx, cex = 2)

## Better is a Quantile-Quantile Plot
qqplot(U, qw <- qwilcox((1:N - 1/2)/N, m = 4, n = 6),
       main = paste("Q-Q-Plot of empirical and theoretical quantiles",
                    "Wilcoxon Statistic, (m=4, n=6)", sep = "\n"))
n <- as.numeric(names(print(tU <- table(U))))
text(n+.2, n+.5, labels = tU, col = "red")

```

window

*Time (Series) Windows***Description**

`window` is a generic function which extracts the subset of the object `x` observed between the times `start` and `end`. If a frequency is specified, the series is then re-sampled at the new frequency.

**Usage**

```

window(x, ...)
## S3 method for class 'ts'
window(x, ...)
## Default S3 method:
window(x, start = NULL, end = NULL,
       frequency = NULL, deltat = NULL, extend = FALSE, ts.eps = getOption("ts.eps"))

window(x, ...) <- value
## S3 replacement method for class 'ts'
window(x, start, end, frequency, deltat, ...) <- value

```

**Arguments**

|                                |  |
|--------------------------------|--|
| <code>x</code>                 | a time-series (or other object if not replacing values).   |
| <code>start</code>             | the start time of the period of interest.  |
| <code>end</code>               | the end time of the period of interest.  |
| <code>frequency, deltat</code> | the new frequency can be specified by either (or both if they are consistent).   |
| <code>extend</code>            | logical. If true, the <code>start</code> and <code>end</code> values are allowed to extend the series. If false, attempts to extend the series give a warning and are ignored.   |
| <code>ts.eps</code>            | time series comparison tolerance. Frequencies are considered equal if their absolute difference is less than <code>ts.eps</code> and boundaries (length-1 versions of <code>start</code> and <code>end</code> ) are checked with <code>fuzz ts.eps/frequency(x)</code> . |
| <code>...</code>               | further arguments passed to or from other methods.   |
| <code>value</code>             | replacement values.  |

## Details

The start and end times can be specified as for `ts`. If there is no observation at the new `start` or `end`, the immediately following (`start`) or preceding (`end`) observation time is used.

The replacement function has a method for `ts` objects, and is allowed to extend the series (with a warning). There is no default method.

## Value

The value depends on the method. `window.default` will return a vector or matrix with an appropriate `tsp` attribute.

`window.ts` differs from `window.default` only in ensuring the result is a `ts` object.

If `extend = TRUE` the series will be padded with NAs if needed.

window(presidents, deltat = 1) # All Qtr1s
window(presidents, start = c(1945,3), deltat = 1) # All Qtr3s
window(presidents, 1944, c(1979,2), extend = TRUE)

pres <- window(presidents, 1945, c(1949,4)) # values in the 1940's
window(pres, 1945.25, 1945.50) <- c(60, 70)
window(pres, 1944, 1944.75) <- 0 # will generate a warning
window(pres, c(1945,4), c(1949,4), frequency = 1) <- 85:89
pres
```

---

xtabs

---

*Cross Tabulation*

---

## Description

Create a contingency table (optionally a sparse matrix) from cross-classifying factors, usually contained in a data frame, using a formula interface.

## Usage

```
xtabs(formula = ~., data = parent.frame(), subset, sparse = FALSE,
      na.action, na.rm = FALSE, addNA = FALSE,
      exclude = if(!addNA) c(NA, NaN), drop.unused.levels = FALSE)

## S3 method for class 'xtabs'
print(x, na.print = "", ...)
```

## Arguments

|                                 |  |
|---------------------------------|--|
| <code>formula</code>            | a <a href="#">formula</a> object with the cross-classifying variables (separated by <code>+</code> ) on the right-hand side (or an object which can be coerced to a formula). Interactions are not allowed. On the left-hand side, one may optionally give a vector or a matrix of counts; in the latter case, the columns are interpreted as corresponding to the levels of a variable. This is useful if the data have already been tabulated, see the examples below. |
| <code>data</code>               | an optional matrix or data frame (or similar: see <a href="#">model.frame</a> ) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .   |
| <code>subset</code>             | an optional vector specifying a subset of observations to be used.   |
| <code>sparse</code>             | logical specifying if the result should be a <i>sparse</i> matrix, i.e., inheriting from <a href="#">sparseMatrix</a> . Only works for two factors (since there are no higher-order sparse array classes yet).   |
| <code>na.action</code>          | a <a href="#">function</a> which indicates what should happen when the variables in <code>formula</code> (or <code>subset</code> ) contain <code>NA</code> s. Defaults to <a href="#">na.pass</a> , so <code>na.rm</code> and <code>addNA</code> , respectively, control the handling of missing values for the two sides of the formula. Using <a href="#">na.omit</a> removes any incomplete cases.  |
| <code>na.rm</code>              | logical: should missing values on the left-hand side of the formula be treated as zero when computing the <code>sum</code> ?   |
| <code>addNA</code>              | logical indicating if <code>NA</code> s in the factors should get a separate level and be counted, using <a href="#">addNA(*, ifany=TRUE)</a> . This has no effect if <code>na.action = na.omit</code> .   |
| <code>exclude</code>            | a vector of values to be excluded when forming the set of levels of the classifying factors.   |
| <code>drop.unused.levels</code> | a logical indicating whether to drop unused levels in the classifying factors. If this is <code>FALSE</code> and there are unused levels, the table will contain zero marginals, and a subsequent chi-squared test for independence of the factors will not work.  |
| <code>x</code>                  | an object of class <code>"xtabs"</code> .  |
| <code>na.print</code>           | character string (or <code>NULL</code> ) indicating how <code>NA</code> are printed. The default ( <code>"</code> ) does not show <code>NA</code> s clearly, and <code>na.print = "NA"</code> maybe advisable instead.   |
| <code>...</code>                | further arguments passed to or from other methods.   |

## Details

There is a `summary` method for contingency table objects created by `table` or `xtabs(*, sparse = FALSE)`, which gives basic information and performs a chi-squared test for independence of factors (note that the function [chisq.test](#) currently only handles 2-d tables).

If a left-hand side is given in `formula`, its entries are simply summed over the cells corresponding to the right-hand side; this also works if the LHS does not give counts.

For variables in `formula` which are factors, `exclude` must be specified explicitly; the default exclusions will not be used.

In R versions before 3.4.0, e.g., when `na.action = na.pass`, sometimes zeroes (0) were returned instead of `NA`s.

In R versions before 4.4.0, when `!addNA` as by default, the default `na.action` was [na.omit](#), effectively treating missing counts as zero.

## Value

By default, when `sparse = FALSE`, a contingency table in array representation of S3 class `c("xtabs", "table")`, with a `"call"` attribute storing the matched call.

When `sparse = TRUE`, a sparse numeric matrix, specifically an object of S4 class `dgTMatrix` from package **Matrix**.

## See Also

`table` for traditional cross-tabulation, and `as.data.frame.table` which is the inverse operation of `xtabs` (see the DF example below).

`sparseMatrix` on sparse matrices in package **Matrix**.

## Examples

```
## 'esoph' has the frequencies of cases and controls for all levels of
## the variables 'agegp', 'alcgp', and 'tobgp'.
xtabs(cbind(ncases, ncontrols) ~ ., data = esoph)
## Output is not really helpful ... flat tables are better:
ftable(xtabs(cbind(ncases, ncontrols) ~ ., data = esoph))
## In particular if we have fewer factors ...
ftable(xtabs(cbind(ncases, ncontrols) ~ agegp, data = esoph))

## This is already a contingency table in array form.
DF <- as.data.frame(UCBAdmissions)
## Now 'DF' is a data frame with a grid of the factors and the counts
## in variable 'Freq'.
DF
## Nice for taking margins ...
xtabs(Freq ~ Gender + Admit, DF)
## And for testing independence ...
summary(xtabs(Freq ~ ., DF))

## with NA's
DN <- DF; DN[cbind(6:9, c(1:2,4,1))] <- NA
DN # 'Freq' is missing only for (Rejected, Female, B)
(xtNA <- xtabs(Freq ~ Gender + Admit, DN)) # NA prints 'invisibly'
print(xtNA, na.print = "NA") # show NA's better
xtabs(Freq ~ Gender + Admit, DN, na.rm = TRUE) # ignore missing Freq
## Use addNA = TRUE to tabulate missing factor levels:
xtabs(Freq ~ Gender + Admit, DN, addNA = TRUE)
xtabs(Freq ~ Gender + Admit, DN, addNA = TRUE, na.rm = TRUE)
## na.action = na.omit removes all rows with NAs right from the start:
xtabs(Freq ~ Gender + Admit, DN, na.action = na.omit)

## Create a nice display for the warp break data.
warpbreaks$replicate <- rep_len(1:9, 54)
ftable(xtabs(breaks ~ wool + tension + replicate, data = warpbreaks))

### ---- Sparse Examples ----

if(require("Matrix")) withAutoprint({
  ## similar to "nlme"s 'ergoStool' :
  d.ergo <- data.frame(Type = paste0("T", rep(1:4, 9*4)),
    Subj = gl(9, 4, 36*4))
  xtabs(~ Type + Subj, data = d.ergo) # 4 replicates each
```

```
set.seed(15) # a subset of cases:
xtabs(~ Type + Subj, data = d.ergo[sample(36, 10), ], sparse = TRUE)

## Hypothetical two-level setup:
inner <- factor(sample(letters[1:25], 100, replace = TRUE))
inout <- factor(sample(LETTERS[1:5], 25, replace = TRUE))
fr <- data.frame(inner = inner, outer = inout[as.integer(inner)])
xtabs(~ inner + outer, fr, sparse = TRUE)
})
```

# Chapter 11

## The stats4 package

---

stats4-package

*Statistical Functions using S4 Classes*

---

### Description

Statistical Functions using S4 classes.

### Details

This package contains functions and classes for statistics using the [S version 4](#) class system.

The methods currently support maximum likelihood (function `mle()` returning class "`mle`"), including methods for `logLik` for use with `AIC`.

### Author(s)

R Core Team and contributors worldwide

Maintainer: R Core Team <[R-core@r-project.org](mailto:R-core@r-project.org)>

---

coef-methods

*Methods for Function `coef` in Package **stats4***

---

### Description

Extract the coefficient vector from "`mle`" objects.

### Methods

`signature(object = "ANY")` Generic function: see `coef`.

`signature(object = "mle")` Extract the full coefficient vector (including any fixed coefficients) from the fit.

`signature(object = "summary.mle")` Extract the coefficient vector and standard errors from the summary of the fit.

---

|                 |   |
|-----------------|---|
| confint-methods | <i>Methods for Function confint in Package stats4</i> |
|-----------------|---|

---

**Description**

Generate confidence intervals

**Methods**

signature(object = "ANY") Generic function: see [confint](#).  
signature(object = "mle") First generate profile and then confidence intervals from the profile.  
signature(object = "profile.mle") Generate confidence intervals based on likelihood profile.

---

|                |  |
|----------------|--|
| logLik-methods | <i>Methods for Function logLik in Package stats4</i> |
|----------------|--|

---

**Description**

Extract the maximized log-likelihood from "mle" objects.

**Methods**

signature(object = "ANY") Generic function: see [logLik](#).  
signature(object = "mle") Extract log-likelihood from the fit.

**Note**

The `mle` method does not know about the number of observations unless `nobs` was specified on the call and so may not be suitable for use with [BIC](#).

---

|     |                                      |
|-----|--------------------------------------|
| mle | <i>Maximum Likelihood Estimation</i> |
|-----|--------------------------------------|

---

**Description**

Estimate parameters by the method of maximum likelihood.

**Usage**

```
mle(minuslogl, start,
    optim = stats::optim,
    method = if(!useLim) "BFGS" else "L-BFGS-B",
    fixed = list(), nobs, lower, upper, ...)
```

## Arguments

|                           |   |
|---------------------------|---|
| <code>minuslogl</code>    | Function to calculate negative log-likelihood.  |
| <code>start</code>        | Named list of vectors or single vector. Initial values for optimizer. By default taken from the default arguments of <code>minuslogl</code> . |
| <code>optim</code>        | Optimizer function. (Experimental)  |
| <code>method</code>       | Optimization method to use. See <a href="#">optim</a> .   |
| <code>fixed</code>        | Named list of vectors or single vector. Parameter values to keep fixed during optimization.   |
| <code>nobs</code>         | optional integer: the number of observations, to be used for e.g. computing <a href="#">BIC</a> .   |
| <code>lower, upper</code> | Named lists of vectors or single vectors. Bounds for <a href="#">optim</a> , if relevant.   |
| <code>...</code>          | Further arguments to pass to <a href="#">optim</a> .  |

## Details

The `optim` optimizer is used to find the minimum of the negative log-likelihood. An approximate covariance matrix for the parameters is obtained by inverting the Hessian matrix at the optimum. By default, [optim](#) from the `stats` package is used; other optimizers need to be plug-compatible, both with respect to arguments and return values.

The function `minuslogl` should take one or several arguments, each of which can be a vector. The optimizer optimizes a function which takes a single vector argument, containing the concatenation of the arguments to `minuslogl`, removing any values that should be held fixed. This function internally unpacks the argument vector, inserts the fixed values and calls `minuslogl`.

The vector arguments `start`, `fixed`, `upper`, and `lower`, can be given in both packed and unpacked form, either as a single vector or as a list of vectors. In the latter case, you only need to specify those list elements that are actually affected. For vector arguments, including those inside lists, use a default marker for those values that you don't want to set: `NA` for `fixed` and `start`, and `+Inf`, `-Inf` for `upper`, and `lower`.

## Value

An object of class `mle-class`.

## Note

Notice that the `mll` argument should calculate  $-\log L$  (not  $-2 \log L$ ). It is for the user to ensure that the likelihood is correct, and that asymptotic likelihood inference is valid.

## See Also

[mle-class](#)

## Examples

```
## Avoid printing to unwarranted accuracy
od <- options(digits = 5)

## Simulated EC50 experiment with count data
x <- 0:10
y <- c(26, 17, 13, 12, 20, 5, 9, 8, 5, 4, 8)

## Easy one-dimensional MLE:
```

```

nLL <- function(lambda) -sum(stats::dpois(y, lambda, log = TRUE))
fit0 <- mle(nLL, start = list(lambda = 5), nobs = NROW(y))

## sanity check --- notice that "nobs" must be input
## (not guaranteed to be meaningful for any likelihood)
stopifnot(nobs(fit0) == length(y))

# For 1D, this is preferable:
fit1 <- mle(nLL, start = list(lambda = 5), nobs = NROW(y),
           method = "Brent", lower = 1, upper = 20)

## This needs a constrained parameter space: most methods will accept NA
ll <- function(ymax = 15, xhalf = 6) {
  if(ymax > 0 && xhalf > 0)
    -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
  else NA
}
(fit <- mle(ll, nobs = length(y)))
mle(ll, fixed = list(xhalf = 6))

## Alternative using bounds on optimization
ll2 <- function(ymax = 15, xhalf = 6)
  -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
mle(ll2, lower = rep(0, 2))

AIC(fit)
BIC(fit)

summary(fit)
logLik(fit)
vcov(fit)
plot(profile(fit), absVal = FALSE)
confint(fit)

## Use bounded optimization
## The lower bounds are really > 0,
## but we use >=0 to stress-test profiling
(fit2 <- mle(ll2, lower = c(0, 0)))
plot(profile(fit2), absVal = FALSE)

## A better parametrization:
ll3 <- function(lymax = log(15), lxhalf = log(6))
  -sum(stats::dpois(y, lambda = exp(lymax)/(1+exp(lxhalf)), log = TRUE))
(fit3 <- mle(ll3))
plot(profile(fit3), absVal = FALSE)
exp(confint(fit3))

# Regression tests for bounded cases (this was broken in R 3.x)
fit4 <- mle(ll, lower = c(0, 4)) # has max on boundary
confint(fit4)

## direct check that fixed= and constraints work together
mle(ll, lower = c(0, 4), fixed=list(ymax=23)) # has max on boundary

## Linear regression using MLE
x <- 1:10

```

```

y <- c(0.48, 2.24, 2.22, 5.15, 4.64, 5.53, 7, 8.8, 7.67, 9.23)

LM_mll <- function(formula, data = environment(formula))
{
  y <- model.response(model.frame(formula, data))
  X <- model.matrix(formula, data)
  b0 <- numeric(NCOL(X))
  names(b0) <- colnames(X)
  function(b=b0, sigma=1)
    -sum(dnorm(y, X %*% b, sigma, log=TRUE))
}

mll <- LM_mll(y ~ x)

summary(lm(y~x)) # for comparison -- notice variance bias in MLE
summary(mle(mll, lower=c(-Inf,-Inf, 0.01)))
summary(mle(mll, lower=list(sigma = 0.01))) # alternative specification

confint(mle(mll, lower=list(sigma = 0.01)))
plot(profile(mle(mll, lower=list(sigma = 0.01))))

Binom_mll <- function(x, n)
{
  force(x); force(n) ## beware lazy evaluation
  function(p=.5) -dbinom(x, n, p, log=TRUE)
}

## Likelihood functions for different x.
## This code goes wrong, if force(x) is not used in Binom_mll:

curve(Binom_mll(0, 10)(p), xname="p", ylim=c(0, 10))
mll_list <- list(10)
for (x in 1:10)
  mll_list[[x]] <- Binom_mll(x, 10)
for (mll in mll_list)
  curve(mll(p), xname="p", add=TRUE)

mll <- Binom_mll(4,10)
mle(mll, lower = 1e-16, upper = 1-1e-16) # limits must be inside (0,1)

## Boundary case: This works, but fails if limits are set closer to 0 and 1
mll <- Binom_mll(0, 10)
mle(mll, lower=.005, upper=.995)

## Not run:
## We can use limits closer to the boundaries if we use the
## drop-in replacement optimr() from the optimx package.

mle(mll, lower = 1e-16, upper = 1-1e-16, optim=optimx::optimr)

## End(Not run)

options(od)

```

mle-class

*Class "mle" for Results of Maximum Likelihood Estimation*

## Description

This class encapsulates results of a generic maximum likelihood procedure.

## Objects from the Class

Objects can be created by calls of the form `new("mle", ...)`, but most often as the result of a call to `mle`.

## Slots

`call`: Object of class "language". The call to `mle`.

`coef`: Object of class "numeric". Estimated parameters.

`fullcoef`: Object of class "numeric". Full parameter set of fixed and estimated parameters.

`fixed`: Object of class "numeric". Fixed parameter values (NA for non-fixed parameters).

`vcov`: Object of class "matrix". Approximate variance-covariance matrix.

`min`: Object of class "numeric". Minimum value of objective function.

`details`: a "list", as returned from `optim`.

`minuslogl`: Object of class "function". The negative loglikelihood function.

`nobs`: "integer" of length one. The number of observations (often NA, when not set in call explicitly).

`method`: Object of class "character". The optimization method used.

## Methods

**confint** signature(object = "mle"): Confidence intervals from likelihood profiles.

**logLik** signature(object = "mle"): Extract maximized log-likelihood.

**profile** signature(fitted = "mle"): Likelihood profile generation.

**nobs** signature(object = "mle"): Number of observations, here simply accessing the `nobs` slot mentioned above.

**show** signature(object = "mle"): Display object briefly.

**summary** signature(object = "mle"): Generate object summary.

**update** signature(object = "mle"): Update fit.

**vcov** signature(object = "mle"): Extract variance-covariance matrix.

plot-methods

*Methods for Function plot in Package stats4***Description**

Plot profile likelihoods for "mle" objects.

**Usage**

```
## S4 method for signature 'profile.mle,missing'
plot(x, levels, conf = c(99, 95, 90, 80, 50)/100, nseg = 50,
     absVal = TRUE, ...)
```

**Arguments**

|        |   |
|--------|---|
| x      | an object of class "profile.mle"  |
| levels | levels, on the scale of the absolute value of a t statistic, at which to interpolate intervals. Usually conf is used instead of giving levels explicitly. |
| conf   | a numeric vector of confidence levels for profile-based confidence intervals on the parameters.   |
| nseg   | an integer value giving the number of segments to use in the spline interpolation of the profile t curves.  |
| absVal | a logical value indicating whether or not the plots should be on the scale of the absolute value of the profile t. Defaults to TRUE.                      |
| ...    | other arguments to the plot function can be passed here.  |

**Methods**

signature(x = "ANY", y = "ANY") Generic function: see [plot](#).

signature(x = "profile.mle", y = "missing") Plot likelihood profiles for x.

profile-methods

*Methods for Function profile in Package stats4***Description**

Profile likelihood for "mle" objects.

**Usage**

```
## S4 method for signature 'mle'
profile(fitted, which = 1:p, maxsteps = 100, alpha = 0.01,
       zmax = sqrt(qchisq(1 - alpha, 1L)), del = zmax/5,
       trace = FALSE, ...)
```

**Arguments**

|          |   |
|----------|---|
| fitted   | Object to be profiled   |
| which    | Optionally select subset of parameters to profile.  |
| maxsteps | Maximum number of steps to bracket zmax.  |
| alpha    | Significance level corresponding to zmax, based on a Scheffe-style multiple testing interval. Ignored if zmax is specified. |
| zmax     | Cutoff for the profiled value of the signed root-likelihood.  |
| del      | Initial stepsize on root-likelihood scale.  |
| trace    | Logical. Print intermediate results.  |
| ...      | Currently unused.   |

**Details**

The profiling algorithm tries to find an approximately evenly spaced set of at least five parameter values (in each direction from the optimum) to cover the root-likelihood function. Some care is taken to try and get sensible results in cases of high parameter curvature. Notice that it may not always be possible to obtain the cutoff value, since the likelihood might level off.

**Value**

An object of class "profile.mle", see "profile.mle-class".

**Methods**

signature(fitted = "ANY") Generic function: see [profile](#).  
signature(fitted = "mle") Profile the likelihood in the vicinity of the optimum of an "mle" object.

---

profile.mle-class    *Class "profile.mle"; Profiling information for "mle" object*

---

**Description**

Likelihood profiles along each parameter of likelihood function

**Objects from the Class**

Objects can be created by calls of the form `new("profile.mle", ...)`, but most often by invoking `profile` on an "mle" object.

**Slots**

**profile:** Object of class "list". List of profiles, one for each requested parameter. Each profile is a data frame with the first column called `z` being the signed square root of the -2 log likelihood ratio, and the others being the parameters with names prefixed by `par.vals`.  
**summary:** Object of class "summary.mle". Summary of object being profiled.

Methods

**confint** signature(object = "profile.mle"): Use profile to generate approximate confidence intervals for parameters.

**plot** signature(x = "profile.mle", y = "missing"): Plot profiles for each parameter.

---

Description

Summarize objects

Methods

signature(object = "ANY") Generic function

signature(object = "mle") Generate a summary as an object of class `"summary.mle"`, containing estimates, asymptotic SE, and value of  $-2 \log L$ .

---

```
summary.mle-class  Class "summary.mle", Summary of "mle" Objects
```

---

### Description

Extract of "mle" object

### Objects from the Class

Objects can be created by calls of the form `new("summary.mle", ...)`, but most often by invoking `summary` on an "mle" object. They contain values meant for printing by `show`.

### Slots

**call:** Object of class "language" The call that generated the "mle" object.

**coef:** Object of class "matrix". Estimated coefficients and standard errors

**m2logL:** Object of class "numeric". Minus twice the log likelihood.

### Methods

**show** signature(object = "summary.mle"): Pretty-prints object

**coef** signature(object = "summary.mle"): Extracts the contents of the `coef` slot

### See Also

```
update-methods  Methods for Function update in Package stats4
```

---

### Description

Update "mle" objects.

### Usage

```
## S4 method for signature 'mle'
update(object, ..., evaluate = TRUE)
```

### Arguments

|                       |   |
|-----------------------|---|
| <code>object</code>   | An existing fit.  |
| <code>...</code>      | Additional arguments to the call, or arguments with changed values. Use <code>name = NULL</code> to remove the argument <code>name</code> . |
| <code>evaluate</code> | If true evaluate the new call else return the call.   |

**Methods**

`signature(object = "ANY")` Generic function: see [update](#).

`signature(object = "mle")` Update a fit.

**Examples**

```
x <- 0:10
y <- c(26, 17, 13, 12, 20, 5, 9, 8, 5, 4, 8)
ll <- function(ymax = 15, xhalf = 6)
  -sum(stats::dpois(y, lambda = ymax/(1+x/xhalf), log = TRUE))
fit <- mle(ll)
## note the recorded call contains ..1, a problem with S4 dispatch
update(fit, fixed = list(xhalf = 3))
```

---

vcov-methods

*Methods for Function `vcov` in Package **stats4***

---

**Description**

Extract the approximate variance-covariance matrix from "mle" objects.

**Methods**

`signature(object = "ANY")` Generic function: see [vcov](#).

`signature(object = "mle")` Extract the estimated variance-covariance matrix for the estimated parameters (if any).

## Chapter 12

# The `tcltk` package

---

`tcltk-package`

*Tcl/Tk Interface*

---

### Description

Interface and language bindings to Tcl/Tk GUI elements.

### Details

This package provides access to the platform-independent Tcl scripting language and Tk GUI elements. See [TkWidgets](#) for a list of supported widgets, [TkWidgetcmds](#) for commands to work with them, and references in those files for more.

The Tcl/Tk documentation is in the system man pages.

For a complete list of functions, use `ls ("package:tcltk")`.

Note that Tk will not be initialized if there is no `DISPLAY` variable set, but Tcl can still be used. This is most useful to allow the loading of a package which depends on `tcltk` in a session that does not actually use it (e.g., during installation).

### Author(s)

R Core Team

Maintainer: R Core Team <R-core@r-project.org>

---

`TclInterface`

*Low-level Tcl/Tk Interface*

---

### Description

These functions and variables provide the basic glue between R and the Tcl interpreter and Tk GUI toolkit. Tk windows may be represented via R objects. Tcl variables can be accessed via objects of class `tclVar` and the C level interface to Tcl objects is accessed via objects of class `tclObj`.

**Usage**

```

.Tcl(...)
.Tcl.objv(objv)
.Tcl.args(...)
.Tcl.args.objv(...)
.Tcl.callback(...)
.Tk.ID(win)
.Tk.newwin(ID)
.Tk.subwin(parent)
.TkRoot
.TkUp

tkdestroy(win)
is.tkwin(x)

tclvalue(x)
tclvalue(x) <- value

tclVar(init = "")
## S3 method for class 'tclVar'
as.character(x, ...)
## S3 method for class 'tclVar'
tclvalue(x)
## S3 replacement method for class 'tclVar'
tclvalue(x) <- value

tclArray()
## S3 method for class 'tclArray'
x[[...]]
## S3 replacement method for class 'tclArray'
x[[...]] <- value
## S3 method for class 'tclArray'
x$i
## S3 replacement method for class 'tclArray'
x$i <- value

## S3 method for class 'tclArray'
names(x)
## S3 method for class 'tclArray'
length(x)

tclObj(x)
tclObj(x) <- value
## S3 method for class 'tclVar'
tclObj(x)
## S3 replacement method for class 'tclVar'
tclObj(x) <- value

as.tclObj(x, drop = FALSE)
is.tclObj(x)

## S3 method for class 'tclObj'

```

```

as.character(x, ...)
## S3 method for class 'tclObj'
as.integer(x, ...)
## S3 method for class 'tclObj'
as.double(x, ...)
## S3 method for class 'tclObj'
as.logical(x, ...)
## S3 method for class 'tclObj'
as.raw(x, ...)
## S3 method for class 'tclObj'
tclvalue(x)

## Default S3 method:
tclvalue(x)
## Default S3 replacement method:
tclvalue(x) <- value

addTclPath(path = ".")
tclRequire(package, warn = TRUE)
tclVersion()

```

### Arguments

|                      |  |
|----------------------|--|
| <code>objv</code>    | a named vector of Tcl objects  |
| <code>win</code>     | a window structure   |
| <code>x</code>       | an object  |
| <code>i</code>       | character or (unquoted) name   |
| <code>drop</code>    | logical. Indicates whether a single-element vector should be made into a simple Tcl object or a list of length one                     |
| <code>value</code>   | For <code>tclvalue</code> assignments, a character string. For <code>tclObj</code> assignments, an object of class <code>tclObj</code> |
| <code>ID</code>      | a window ID  |
| <code>parent</code>  | a window which becomes the parent of the resulting window  |
| <code>path</code>    | path to a directory containing Tcl packages  |
| <code>package</code> | a Tcl package name   |
| <code>warn</code>    | logical. Warn if not found?  |
| <code>...</code>     | Additional arguments. See below.   |
| <code>init</code>    | initialization value   |

### Details

Many of these functions are not intended for general use but are used internally by the commands that create and manipulate Tk widgets and Tcl objects. At the lowest level `.Tcl` sends a command as a text string to the Tcl interpreter and returns the result as an object of class `tclObj` (see below). A newer variant `.Tcl.objv` accepts arguments in the form of a named list of `tclObj` objects.

`.Tcl.args` converts an R argument list of `tag = value` pairs to the Tcl `-option value` style, thus enabling a simple translation between the two languages. To send a value with no preceding option flag to Tcl, just use an untagged argument. In the rare case one needs an option with

no subsequent value `tag = NULL` can be used. Most values are just converted to character mode and inserted in the command string, but window objects are passed using their ID string, and callbacks are passed via the result of `.Tcl.callback`. Tags are converted to option flags simply by prepending a `-`

`.Tcl.args.objv` serves a similar purpose as `.Tcl.args` but produces a list of `tclObj` objects suitable for passing to `.Tcl.objv`. The names of the list are converted to Tcl option style internally by `.Tcl.objv`.

Callbacks can be either *atomic callbacks* handled by `.Tcl.callback` or expressions. An expression is treated as a list of atomic callbacks, with the following exceptions: if an element is a name, it is first evaluated in the callers frame, and likewise if it is an explicit function definition; the `break` expression is translated directly to the Tcl counterpart. `.Tcl.callback` converts R functions and unevaluated calls to Tcl command strings. The argument must be either a function closure or an object of mode `"call"` followed by an environment. The return value in the first case is of the form `R_call 0x408b94d4` in which the hexadecimal number is the memory address of the function. In the second case it will be of the form `R_call_lang 0x8a95904 0x819bfd0`. For expressions, a sequence of similar items is generated, separated by semicolons. `.Tcl.args` takes special precautions to ensure that functions or calls will continue to exist at the specified address by assigning the callback into the relevant window environment (see below).

Tk windows are represented as objects of class `tkwin` which are lists containing a `ID` field and an `env` field which is an R environments, enclosed in the global environment. The value of the `ID` field is identical to the Tk window name. The `env` environment contains a `parent` variable and a `num.subwin` variable. If the window obtains sub-windows and callbacks, they are added as variables to the environment. `.TkRoot` is the top window with ID `"."`; this window is not displayed in order to avoid ill effects of closing it via window manager controls. The `parent` variable is undefined for `.TkRoot`.

`.Tk.ID` extracts the ID of a window, `.Tk.newwin` creates a new window environment with a given ID and `.Tk.subwin` creates a new window which is a sub-window of a given parent window.

`.TkUp` is a logical flag to indicate whether the Tk widget system is active; if `FALSE`, only the Tcl interpreter is available.

`tkdestroy` destroys a window and also removes the reference to a window from its parent.

`is.tkwin` can be used to test whether a given object is a window environment.

`tclVar` creates a new Tcl variable and initializes it to `init`. An R object of class `tclVar` is created to represent it. Using `as.character` on the object returns the Tcl variable name. Accessing the Tcl variable from R is done using the `tclvalue` function, which can also occur on the left-hand side of assignments. If `tclvalue` is passed an argument which is not a `tclVar` object, then it will assume that it is a character string explicitly naming global Tcl variable. Tcl variables created by `tclVar` are uniquely named and automatically unset by the garbage collector when the representing object is no longer in use.

`tclArray` creates a new Tcl array and initializes it to the empty array. An R object of class `tclArray` and inheriting from class `tclVar` is created to represent it. You can access elements of the Tcl array using indexing with `[]` or `$`, which also allow replacement forms. Notice that Tcl arrays are associative by nature and hence unordered; indexing with a numeric index `i` refers to the element with the *name* `as.character(i)`. Multiple indices are pasted together separated by commas to form a single name. You can query the length and the set of names in an array using methods for `length` and `names`, respectively; these cannot meaningfully be set so assignment forms exist only to print an error message.

It is possible to access Tcl's 'dual-ported' objects directly, thus avoiding parsing and deparsing of their string representation. This works by using objects of class `tclObj`. The string representation

of such objects can be extracted (but not set) using `tclvalue` and conversion to vectors of mode "character", "double", "integer", "logical", and "raw" is performed using the standard coercion functions `as.character`, etc. Conversely, such vectors can be converted using `as.tclObj`. There is an ambiguity as to what should happen for length one vectors, controlled by the `drop` argument; there are cases where the distinction matters to Tcl, although mostly it treats them equivalently. Notice that `tclvalue` and `as.character` differ on an object whose string representation has embedded spaces, the former is sometimes to be preferred, in particular when applied to the result of `tclread`, `tkgetOpenFile`, and similar functions. The `as.raw` method returns a raw vector or a list of raw vectors and can be used to return binary data from Tcl.

The object behind a `tclVar` object is extracted using `tclObj(x)` which also allows an assignment form, in which the right hand side of the assignment is automatically converted using `as.tclObj`. There is a print method for `tclObj` objects; it prints '<Tcl>' followed by the string representation of the object. Notice that `as.character` on a `tclVar` object is the *name* of the corresponding Tcl variable and not the value.

Tcl packages can be loaded with `tclRequire`; it may be necessary to add the directory where they are found to the Tcl search path with `addTclPath`. The return value is a class "tclObj" object if it succeeds, or FALSE if it fails (when a warning is issued). To see the current search path as an R character vector, use:

```
strsplit(tclvalue('auto_path'), " ")[[1]]
```

The Tcl version (including patch level) is returned as a character string (such as "8.6.3").

### Note

Strings containing unbalanced braces are currently not handled well in many circumstances.

### See Also

[TkWidgets](#), [TkCommands](#), [TkWidgetcmds](#).

[capabilities](#)("tcltk") to see if Tcl/Tk support was compiled into this build of R.

### Examples

```
tclVersion()

.Tcl("format \"%s\n\" \"Hello, World!\")

f <- function() cat("HI!\n")
.Tcl.callback(f)
.Tcl.args(text = "Push!", command = f) # NB: Different address

xyzzzy <- tclVar(7913)
tclvalue(xyzzzy)
tclvalue(xyzzzy) <- "foo"
as.character(xyzzzy)
tcl("set", as.character(xyzzzy))

## Not run:
## These cannot be run by example() but should be OK when pasted
## into an interactive R session with the tcltk package loaded
top <- tktoplevel() # a Tk widget, see Tk-widgets
ls(envir = top$env, all.names = TRUE)
```

```
## End(Not run)

ls(envir = .TkRoot$env, all.names = TRUE) # .Tcl.args put a callback ref in here
```

---

|                |   |
|----------------|---|
| tclServiceMode | <i>Allow Tcl events to be serviced or not</i> |
|----------------|---|

---

## Description

This function controls or reports on the Tcl service mode, i.e., whether Tcl will respond to events.

## Usage

```
tclServiceMode(on = NULL)
```

## Arguments

|    |   |
|----|---|
| on | (logical) Whether event servicing is turned on. |
|----|---|

## Details

If called with `on == NULL` (the default), no change is made.

Note that this blocks all Tcl/Tk activity, including for widgets from other packages. It may be better to manage mapping of windows individually.

## Value

The value of the Tcl service mode before the call.

## Examples

```
## see demo(tkcanvas) for an example
oldmode <- tclServiceMode(FALSE)
# Do some work to create a nice picture.
# Nothing will be displayed until...
tclServiceMode(oldmode)
## another idea is to use tkwm.withdraw() ... tkwm.deiconify()
```

---

TkCommands*Tk non-widget commands*

---

**Description**

These functions interface to Tk non-widget commands, such as the window manager interface commands and the geometry managers.

**Usage**

```
tcl(...)
tktitle(x)

tktitle(x) <- value

### Arguments

|       |   |
|-------|---|
| x     | A window object   |
| value | For <code>tktitle</code> assignments, a character string. |
| ...   | Handled via <code>.Tcl.args</code>                        |

## Details

`tcl` provides a generic interface to calling any Tk or Tcl command by simply running `.Tcl.args.objv` on the argument list and passing the result to `.Tcl.objv`. Most of the other commands simply call `tcl` with a particular first argument and sometimes also a second argument giving the subcommand.

`tktitle` and its assignment form provides an alternate interface to Tk's `wm title`

There are far too many of these commands to describe them and their arguments in full. Please refer to the Tcl/Tk documentation for details. With a few exceptions, the pattern is that Tk subcommands like `pack` `configure` are converted to function names like `tkpack.configure`, and Tcl subcommands are like `tclfile.dir`.

## See Also

[TclInterface](#), [TkWidgets](#), [TkWidgetcmds](#)

## Examples

```
## Not run:
## These cannot be run by examples() but should be OK when pasted
## into an interactive R session with the tcltk package loaded

tt <- tktoplevel()
tkpack(l1 <- tklabel(tt, text = "Heave"), l2 <- tklabel(tt, text = "Ho"))
tkpack.configure(l1, side = "left")

## Try stretching the window and then

tkdestroy(tt)

## End(Not run)
```

---

tkpager

---

*Page file using Tk text widget*

---

## Description

This plugs into `file.show`, showing files in separate windows.

## Usage

```
tkpager(file, header, title, delete.file)
```

## Arguments

|                          |   |
|--------------------------|---|
| <code>file</code>        | character vector containing the names of the files to be displayed                                  |
| <code>header</code>      | headers to use for each file  |
| <code>title</code>       | common title to use for the window(s). Pasted together with the header to form actual window title. |
| <code>delete.file</code> | logical. Should file(s) be deleted after display?   |

**Note**

The "\b\_" string used for underlining is currently quietly removed. The font and background colour are currently hardcoded to Courier and gray90.

**See Also**

`file.show`

---

|               |                             |
|---------------|-----------------------------|
| tkProgressBar | <i>Progress Bars via Tk</i> |
|---------------|-----------------------------|

---

**Description**

Put up a Tk progress bar widget.

**Usage**

```
tkProgressBar(title = "R progress bar", label = "",
              min = 0, max = 1, initial = 0, width = 300)

getTkProgressBar(pb)
setTkProgressBar(pb, value, title = NULL, label = NULL)
## S3 method for class 'tkProgressBar'
close(con, ...)
```

**Arguments**

|                             |   |
|-----------------------------|---|
| <code>title, label</code>   | character strings, giving the window title and the label on the dialog box respectively.      |
| <code>min, max</code>       | (finite) numeric values for the extremes of the progress bar.                                 |
| <code>initial, value</code> | initial or new value for the progress bar.  |
| <code>width</code>          | the width of the progress bar in pixels: the dialog box will be 40 pixels wider (plus frame). |
| <code>pb, con</code>        | an object of class "tkProgressBar".   |
| <code>...</code>            | for consistency with the generic.   |

**Details**

`tkProgressBar` will display a widget containing a label and progress bar.

`setTkProgressbar` will update the value and for non-NULL values, the title and label (provided there was one when the widget was created). Missing (NA) and out-of-range values of `value` will be (silently) ignored.

The progress bar should be `closed` when finished with.

This will use the `ttk::progressbar` widget for Tk version 8.5 or later, otherwise R's copy of `BWidget's progressbar`.

**Value**

For `tkProgressBar` an object of class `"tkProgressBar"`.

For `getTkProgressBar` and `setTkProgressBar`, a length-one numeric vector giving the previous value (invisibly for `setTkProgressBar`).

**See Also**

[txtProgressBar](#)

**Examples**

```
pb <- tkProgressBar("test progress bar", "Some information in %",
                    0, 100, 50)
Sys.sleep(0.5)
u <- c(0, sort(runif(20, 0, 100)), 100)
for(i in u) {
  Sys.sleep(0.1)
  info <- sprintf("%d%% done", round(i))
  setTkProgressBar(pb, i, sprintf("test (%s)", info), info)
}
Sys.sleep(5)
close(pb)
```

---

tkStartGUI

*Tcl/Tk GUI startup*

---

**Description**

Starts up the Tcl/Tk GUI

**Usage**

```
tkStartGUI()
```

**Details**

Starts a GUI console implemented via a Tk text widget. This should probably be called at most once per session. Also redefines the file pager (as used by `help()`) to be the Tk pager.

**Note**

`tkStartGUI()` saves its evaluation environment as `.GUIenv`. This means that the user interface elements can be accessed in order to extend the interface. The three main objects are named `Term`, `Menu`, and `Toolbar`, and the various submenus and callback functions can be seen with `ls(envir = .GUIenv)`.

tkpack(txt.w <- tktext(tt))
tkinsert(txt.w, "0.0", "plot(1:10)")

# callback function
eval.txt <- function() eval(str2lang(tclvalue(tkget(txt.w, "0.0", "end"))))
tkpack(but.w <- tkbutton(tt, text = "Submit", command = eval.txt))

## Try pressing the button, edit the text and when finished:

tkdestroy(tt)

## End(Not run)
```

---

TkWidgets

*Tk widgets*

---

**Description**

Create Tk widgets and associated R objects.

**Usage**

```
tkwidget(parent, type, ...)

tkbutton(parent, ...)
tkcanvas(parent, ...)
tkcheckboxbutton(parent, ...)
tkentry(parent, ...)
ttkentry(parent, ...)
```

```

tkframe(parent, ...)
tklabel(parent, ...)
tklistbox(parent, ...)
tkmenu(parent, ...)
tkmenubutton(parent, ...)
tkmessage(parent, ...)
tkradiobutton(parent, ...)
tkscale(parent, ...)
tkscrollbar(parent, ...)
tktext(parent, ...)
tktoplevel(parent = .TkRoot, ...)

ttkbutton(parent, ...)
ttkcheckboxbutton(parent, ...)
ttkcombobox(parent, ...)
ttkframe(parent, ...)
ttklabel(parent, ...)
ttklabelframe(parent, ...)
ttkmenubutton(parent, ...)
ttknotebook(parent, ...)
ttkpanedwindow(parent, ...)
ttkprogressbar(parent, ...)
ttkradiobutton(parent, ...)
ttkscale(parent, ...)
ttkscrollbar(parent, ...)
ttkseparator(parent, ...)
ttksizegrip(parent, ...)
ttkspinbox(parent, ...)
ttktreeview(parent, ...)

```

### Arguments

|        |   |
|--------|---|
| parent | Parent of widget window.                      |
| type   | string describing the type of widget desired. |
| ...    | handled via <code>.Tcl.args</code> .          |

### Details

These functions create Tk widgets. `tkwidget` creates a widget of a given type, the others simply call `tkwidget` with the respective `type` argument.

The functions starting `ttk` are for the themed widget set for Tk 8.5 or later. A tutorial can be found at <https://tkdocs.com/>.

It is not possible to describe the widgets and their arguments in full. Please refer to the Tcl/Tk documentation.

### See Also

[TclInterface](#), [TkCommands](#), [TkWidgetcmds](#)

### Examples

```
## Not run:
```

```
## These cannot be run by examples() but should be OK when pasted
## into an interactive R session with the tcltk package loaded

tt <- tktoplevel()
label.widget <- tklabel(tt, text = "Hello, World!")
button.widget <- tkbutton(tt, text = "Push",
                          command = function() cat("OW!\n"))
tkpack(label.widget, button.widget) # geometry manager
                                   # see Tk-commands

## Push the button and then...

tkdestroy(tt)

## test for themed widgets
if(as.character(tcl("info", "tclversion")) >= "8.5") {
  # make use of themed widgets
  # list themes
  themes <- as.character(tcl("ttk::style", "theme", "names"))
  themes
  # select a theme -- for pre-XP windows
  # tcl("ttk::style", "theme", "use", "winnative")
  tcl("ttk::style", "theme", "use", themes[1])
} else {
  # use Tk 8.0 widgets
}

## End(Not run)
```

tk\_choose.dir

*Choose a Folder Interactively***Description**

Use a Tk widget to choose a directory interactively.

**Usage**

```
tk_choose.dir(default = "", caption = "Select directory")
```

**Arguments**

|         |                                      |
|---------|--------------------------------------|
| default | which directory to show initially.   |
| caption | the caption on the selection dialog. |

**Value**

A length-one character vector, character NA if ‘Cancel’ was selected.

**See Also**

[tk\\_choose.files](#)

## Examples

```
if (interactive()) tk_choose.dir(getwd(), "Choose a suitable folder")
```

---

|                 |   |
|-----------------|---|
| tk_choose.files | <i>Choose a List of Files Interactively</i> |
|-----------------|---|

---

## Description

Use a Tk file dialog to choose a list of zero or more files interactively.

## Usage

```
tk_choose.files(default = "", caption = "Select files",  
                multi = TRUE, filters = NULL, index = 1)
```

## Arguments

|         |  |
|---------|--|
| default | which filename to show initially.                |
| caption | the caption on the file selection dialog.        |
| multi   | whether to allow multiple files to be selected.  |
| filters | two-column character matrix of filename filters. |
| index   | unused.  |

## Details

Unlike [file.choose](#), `tk_choose.files` will always attempt to return a character vector giving a list of files. If the user cancels the dialog, then zero files are returned, whereas [file.choose](#) would signal an error.

The format of `filters` can be seen from the example. File patterns are specified via extensions, with "\*" meaning any file, and "" any file without an extension (a filename not containing a period). (Other forms may work on specific platforms.) Note that the way to have multiple extensions for one file type is to have multiple rows with the same name in the first column, and that whether the extensions are named in file chooser widget is platform-specific. **The format may change before release.**

## Value

A character vector giving zero or more file paths.

## Note

A bug in Tk 8.5.0–8.5.4 prevented multiple selections being used.

## See Also

[file.choose](#), [tk\\_choose.dir](#)

**Examples**

```
Filters <- matrix(c("R code", ".R", "R code", ".s",
                   "Text", ".txt", "All files", "*"),
                 4, 2, byrow = TRUE)

Filters
if(interactive()) tk_choose.files(filter = Filters)
```

tk\_messageBox

*Tk Message Box***Description**

An implementation of a generic message box using Tk.

**Usage**

```
tk_messageBox(type = c("ok", "okcancel", "yesno", "yesnocancel",
                      "retrycancel", "abortretryignore"),
             message, caption = "", default = "", ...)
```

**Arguments**

|         |  |
|---------|--|
| type    | character. The type of dialog box. It will have the buttons implied by its name. Can be abbreviated.                   |
| message | character. The information field of the dialog box.  |
| caption | the caption on the widget displayed.   |
| default | character. The name of the button to be used as the default.   |
| ...     | additional named arguments to be passed to the Tk function of this name. An example is <code>icon = "warning"</code> . |

**Value**

A character string giving the name of the button pressed.

**See Also**

[tkmessageBox](#) for a 'raw' interface.

---

|                |                          |
|----------------|--------------------------|
| tk_select.list | Select Items from a List |
|----------------|--------------------------|

---

### Description

Select item(s) from a character vector using a Tk listbox.

### Usage

```
tk_select.list(choices, preselect = NULL, multiple = FALSE,  
              title = NULL)
```

### Arguments

|           |   |
|-----------|---|
| choices   | a character vector of items.  |
| preselect | a character vector, or NULL. If non-null and if the string(s) appear in the list, the item(s) are selected initially. |
| multiple  | logical: can more than one item be selected?  |
| title     | optional character string for window title, or NULL for no title.   |

### Details

This is a version of `select.list` implemented as a Tk list box plus OK and Cancel buttons. There will be a scrollbar if the list is too long to fit comfortably on the screen.

The dialog box is *modal*, so a selection must be made or cancelled before the R session can proceed. Double-clicking on an item is equivalent to selecting it and then clicking OK.

If Tk is version 8.5 or later, themed widgets will be used.

### Value

A character vector of selected items. If `multiple` is false and no item was selected (or Cancel was used), "" is returned. If `multiple` is true and no item was selected (or Cancel was used) then a character vector of length 0 is returned.

### See Also

`select.list` (a text version except on Windows and the macOS GUI), `menu` (whose `graphics = TRUE` mode uses this on most Unix-alikes).

---

### Description

`.print.via.format` is a “prototype” `print()` method, useful, at least as a start, by a simple

```
print.<myS3class> <- .print.via.format
```

### Usage

```
.print.via.format(x, ...)
```

### Arguments

`x` object to be printed.

`...` optional further arguments, passed to `format`.

**Value**

`x`, invisibly (by `invisible()`), as `print` methods should.

**See Also**

The `print` generic; its default method `print.default` (used for many basic implicit classes such as "numeric", "character" and arrays of them, `lists` etc).

**Examples**

```
## The function is simply defined as
function (x, ...) {
  writeLines(format(x, ...))
  invisible(x)
}

## is used for simple print methods in R, and as prototype for new methods.
```

---

add\_datalist

---

*Add a 'datalist' File to a Source Package*

---

**Description**

The `data()` command with no arguments lists all the datasets available via data in attached packages, and to do so a per-package list is installed. Creating that list at install time can be slow for packages with huge datasets, and can be expedited by supplying a 'data/datalist' file.

**Usage**

```
add_datalist(pkgpath, force = FALSE, small.size = 1024^2)
```

**Arguments**

|                         |  |
|-------------------------|--|
| <code>pkgpath</code>    | The path to a (source) package.  |
| <code>force</code>      | logical: can an existing 'data/datalist' file be over-written?   |
| <code>small.size</code> | number: a 'data/datalist' file is created only if the total size of the data files is larger than <code>small.size</code> bytes. |

**Details**

R CMD build will call this function to add a data list to packages with 1MB or more of file in the 'data' directory.

It can also be also helpful to give a 'data/datalist' file in packages whose datasets have many dependencies, including loading the packages itself (and maybe others).

**See Also**

`data`.

The 'Writing R Extensions' manual.

## Description

When testing code, it is not sufficient to check that results are correct, but also that errors or warnings are signalled in appropriate situations. The functions described here provide a convenient facility for doing so. The three functions check that evaluating the supplied expression produces an error, a warning or one of a specified list of conditions, respectively. If the assertion fails, an error is signalled.

## Usage

```
assertError(expr, classes = "error", verbose = FALSE)
assertWarning(expr, classes = "warning", verbose = FALSE)
assertCondition(expr, ..., .exprString = , verbose = FALSE)
```

## Arguments

|                           |  |
|---------------------------|--|
| <code>expr</code>         | an unevaluated R expression which will be evaluated via <code>tryCatch(expr, ...)</code> .   |
| <code>classes, ...</code> | <code>character</code> strings corresponding to the classes of the conditions that would satisfy the assertion; e.g., "error" or "warning". If none are specified, any condition will satisfy the assertion. See the details section.  |
| <code>.exprString</code>  | The string to be printed corresponding to <code>expr</code> . By default, the actual <code>expr</code> will be deparsed. Will be omitted if the function is supplied with the actual expression to be tested. If <code>assertCondition()</code> is called from another function, with the actual expression passed as an argument to that function, supply the deparsed version. |
| <code>verbose</code>      | If <code>TRUE</code> , a message is printed when the condition is satisfied.   |

## Details

`assertCondition()` uses the general condition mechanism to check all the conditions generated in evaluating `expr`. The occurrence of any of the supplied condition classes among these satisfies the assertion regardless of what other conditions may be signalled.

`assertError()` is a convenience function for asserting errors; it calls `assertCondition()`.

`assertWarning()` asserts that a warning will be signalled, but *not* an error, whereas `assertCondition(expr, "warning")` will be satisfied even if an error follows the warning. See the examples.

## Value

If the assertion is satisfied, a list of all the condition objects signalled is returned, invisibly. See `conditionMessage` for the interpretation of these objects. Note that *all* conditions signalled during the evaluation are returned, whether or not they were among the requirements.

## Author(s)

John Chambers and Martin Maechler

**See Also**

`stop`, `warning`, `signalCondition`, `tryCatch`.

**Examples**

```

assertError(sqrt("abc"))
assertWarning(matrix(1:8, 4,3))

assertCondition( "-1 " ) # ok, any condition would satisfy this

try( assertCondition(sqrt(2), "warning") )
## .. Failed to get warning in evaluating sqrt(2)
  assertCondition(sqrt("abc"), "error") # ok
try( assertCondition(sqrt("abc"), "warning") )# -> error: had no warning
  assertCondition(sqrt("abc"), "error")
## identical to assertError() call above

assertCondition(matrix(1:5, 2,3), "warning")
try( assertCondition(matrix(1:8, 4,3), "error") )
## .. Failed to get expected error ....

## either warning or worse:
assertCondition(matrix(1:8, 4,3), "error","warning") # OK
assertCondition(matrix(1:8, 4, 3), "warning") # OK

## when both are signalled:
ff <- function() { warning("my warning"); stop("my error") }
  assertCondition(ff(), "warning")
## but assertWarning does not allow an error to follow
try(assertWarning(ff()))
  assertCondition(ff(), "error") # ok
assertCondition(ff(), "error", "warning") # ok (quietly, catching warning)

## assert that assertC..() does not assert [and use *one* argument only]
assertCondition( assertCondition(sqrt( 2 ), "warning") )
assertCondition( assertCondition(sqrt("abc"), "warning"), "error")
assertCondition( assertCondition(matrix(1:8, 4,3), "error"),
  "error")

```

---

bibstyle

---

*Select or Define a Bibliography Style*

---

**Description**

This function defines and registers styles for rendering `bibentry` objects into ‘Rd’ format, for later conversion to text, HTML, etc.

**Usage**

```

bibstyle(style, envir, ..., .init = FALSE, .default = TRUE)
getBibstyle(all = FALSE)

```

## Arguments

|                       |   |
|-----------------------|---|
| <code>style</code>    | A character string naming the style.                                    |
| <code>envir</code>    | (optional) An environment holding the functions to implement the style. |
| <code>...</code>      | Named arguments to add to the environment.                              |
| <code>.init</code>    | Whether to initialize the environment from the default style "JSS".     |
| <code>.default</code> | Whether to set the specified style as the default style.                |
| <code>all</code>      | Whether to return the names of all registered styles.                   |

## Details

Rendering of `bibentry` objects may be done using routines modelled after those used by BibTeX. This function allows environments to be created and manipulated to contain those routines.

There are two ways to create a new style environment. The easiest is to set `.init = TRUE`, in which case the environment will be initialized with a copy of the default "JSS" environment. (This style is modelled after the 'jss.bst' style used by the *Journal of Statistical Software*.) Alternatively, the `envir` argument can be used to specify a completely new style environment.

To find the name of the default style, use `getBibstyle()`. To retrieve an existing style without setting it as the default, use `bibstyle(style, .default = FALSE)`. To modify an existing style, specify `style` and some named entries via `...` (Modifying the default "JSS" style is discouraged.) Setting `style` to `NULL` or leaving it missing will retrieve the default style, but modifications will not be allowed.

At a minimum, the environment should contain routines to render each of the 12 types of bibliographic entry supported by `bibentry` as well as several other routines described below. The former must be named `formatArticle`, `formatBook`, `formatInbook`, `formatIncollection`, `formatInProceedings`, `formatManual`, `formatMastersthesis`, `formatMisc`, `formatPhdthesis`, `formatProceedings`, `formatTechreport` and `formatUnpublished`. Each of these takes one argument, a single `unclass`'ed entry from the `bibentry` vector passed to the renderer, and should produce a single element character vector (possibly containing newlines).

The other routines are as follows. `sortKeys`, a function to produce a sort key to sort the entries, is passed the original `bibentry` vector and should produce a sortable vector of the same length to define the sort order. Finally, the optional function `cite` should have the same argument list as `utils::cite`, and should produce a citation to be used in text.

The `format` method for "bibentry" objects adds a field named `".index"` to each entry after sorting and before formatting. This is a 1-based index within the complete object that can be used in styles that require numbering. Although the "JSS" style doesn't use numbers, it includes a `fntPrefix()` stub function that may be used to display them. See the example below.

## Value

`bibstyle` returns the environment which has been selected or created.

`getBibstyle` returns the name of the default style, or all style names.

  address = "Vienna, Austria",
  year = 2013,
  url = "https://www.R-project.org"),
bibentry(bibtype = "article",
  author = c(person(c("George", "E.", "P."), "Box"),
    person(c("David", "R."), "Cox")),
  year = 1964,
  title = "An Analysis of Transformations",
  journal = "Journal of the Royal Statistical Society, Series B",
  volume = 26, number = 2, pages = "211--243",
  doi = "10.1111/j.2517-6161.1964.tb00553.x"))

bibstyle("unsorted", sortKeys = function(refs) seq_along(refs),
  fmtPrefix = function(paper) paste0("[", paper$.index, "]"),
  .init = TRUE)
print(refs, .bibstyle = "unsorted")

```

buildVignette

*Build One Vignette***Description**

Run [Sweave](#) (or other custom weave function), [texi2pdf](#), and/or [Stangle](#) (or other custom tangle function) on one vignette.

This is the workhorse of R CMD Sweave.

**Usage**

```

buildVignette(file, dir = ".", weave = TRUE, latex = TRUE, tangle = TRUE,
  quiet = TRUE, clean = TRUE, keep = character(),
  engine = NULL, buildPkg = NULL, encoding, ...)

```

**Arguments**

|        |   |
|--------|---|
| file   | character; the vignette source file.  |
| dir    | character; the working directory in which the intermediate and output files will be produced. |
| weave  | logical; should weave be run?   |
| latex  | logical; should <a href="#">texi2pdf</a> be run if weaving produces a ‘.tex’ file?            |
| tangle | logical; should tangle be run?  |
| quiet  | logical; run in quiet mode?   |
| clean  | logical; whether to remove some newly created, often intermediate, files. See details below.  |

|          |  |
|----------|--|
| keep     | a list of file names to keep in any case when cleaning. Note that “target” files are kept anyway.  |
| engine   | NULL or character; name of vignette engine to use. Overrides any ‘\VignetteEngine{ }’ markup in the vignette.  |
| buildPkg | NULL or a character vector; optional packages in which to find the vignette engine.  |
| encoding | the encoding to assume for the file. If not specified, it will be read if possible from the file’s contents. Note that if the vignette is part of a package, <a href="#">buildVignettes</a> reads the package’s encoding from the ‘DESCRIPTION’ file but this function does not. |
| ...      | Additional arguments passed to weave and tangle.   |

### Details

This function determines the vignette engine for the vignette (default `utils::Sweave`), then weaves and/or tangles the vignette using that engine. Finally, if `clean` is `TRUE`, newly created intermediate files (non “targets”, where these depend on the engine, etc, and not any in `keep`) will be deleted. If `clean` is `NA`, and `weave` is true, newly created intermediate output files (e.g., ‘.tex’) will not be deleted even if a ‘.pdf’ file has been produced from them.

If `buildPkg` is specified, those packages will be loaded before the vignette is processed and will be used as the default packages in the search for a vignette engine, but an explicitly specified package in the vignette source (e.g., using ‘\VignetteEngine{utils::Sweave}’ to specify the Sweave engine in the `utils` package) will override it. In contrast, if the `engine` argument is given, it will override the vignette source.

### Value

A character vector naming the files that have been produced.

### Author(s)

Henrik Bengtsson and Duncan Murdoch

### See Also

[buildVignettes](#) for building all vignettes in a package.

---

buildVignettes

*List and Build Package Vignettes*

---

### Description

Run [Sweave](#) (or other custom weave function) and [texi2pdf](#) on all vignettes of a package, or list the vignettes.

**Usage**

```
buildVignettes(package, dir, lib.loc = NULL, quiet = TRUE,
               clean = TRUE, tangle = FALSE, skip = NULL,
               ser_elibs = NULL)

pkgVignettes(package, dir, subdirs = NULL, lib.loc = NULL,
             output = FALSE, source = FALSE, check = FALSE)
```

**Arguments**

|           |  |
|-----------|--|
| package   | a character string naming an installed package. If given, vignette source files are by default looked for in subdirectory 'doc'.   |
| dir       | a character string specifying the path to a package's root source directory. If given, vignette source files are by default looked for in subdirectory 'vignettes'.  |
| lib.loc   | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.   |
| quiet     | logical. Weave and run <a href="#">texi2pdf</a> in quiet mode.   |
| clean     | Remove all files generated by the build, even if there were copies there before.   |
| tangle    | logical. Do tangling as well as weaving.   |
| skip      | a character vector of names of vignettes (without file extension, matching the names returned from <code>pkgVignettes</code> ) which should be skipped, or TRUE to skip those with unavailable '\VignetteDepends' (from <a href="#">vignetteInfo</a> ).  |
| ser_elibs | For use from R CMD check.  |
| subdirs   | a character vector of subdirectories of <code>dir</code> in which to look for vignettes. The first which exists is used. Defaults to "doc" if <code>package</code> is supplied, otherwise "vignettes".   |
| output    | logical indicating if the output filenames for each vignette should be returned (in component outputs).  |
| source    | logical indicating if the <i>tangled</i> output filenames for each vignette should be returned (in component sources).   |
| check     | logical. If TRUE, check whether all files that have vignette-like filenames have an identifiable vignette engine. This may be a false positive if a file is not a vignette but has a filename matching a pattern defined by one of the vignette engines. |

**Details**

`buildVignettes` is used by R CMD `build` and R CMD `check` to (re-)build vignette outputs from their sources.

As from R 3.4.1, both of these functions ignore files that are listed in the '.Rbuildignore' file in `dir`.

**Value**

`buildVignettes` is called for its side effect of creating the outputs of all vignettes, and if `tangle = TRUE`, extracting the R code.

`pkgVignettes` returns an object of class "pkgVignettes" if a vignette directory is found, otherwise NULL.

## Examples

```
gVigns <- pkgVignettes("grid")
str(gVigns)
```

---

charsets

---

*Conversion Tables between Character Sets*

---

## Description

`charset_to_Unicode` is a matrix of Unicode code points with columns for the common 8-bit encodings.

`Adobe_glyphs` is a data frame which gives Adobe glyph names for Unicode code points. It has two character columns, "adobe" and "unicode" (a 4-digit hex representation).

## Usage

```
charset_to_Unicode
```

```
Adobe_glyphs
```

## Details

`charset_to_Unicode` is an integer matrix of class `c("noquote", "hexmode")` so prints in hexadecimal. The mappings are those used by `libiconv`: there are differences in the way quotes and minus/hyphen are mapped between sources (and the postscript encoding files use a different mapping).

`Adobe_glyphs` includes all the Adobe glyph names which correspond to single Unicode characters. It is sorted by Unicode code point and within a point alphabetically on the glyph (there can be more than one name for a Unicode code point). The data are in the file '[R\\_HOME/share/encodings/Adobe\\_glyphlist](#)'.

## Examples

```
## find Adobe names for ISOLatin2 chars.
latin2 <- charset_to_Unicode[, "ISOLatin2"]
aUnicode <- as.hexmode(paste0("0x", Adobe_glyphs$unicode))
keep <- aUnicode %in% latin2
aUnicode <- aUnicode[keep]
aAdobe <- Adobe_glyphs[keep, 1]
## first match
aLatin2 <- aAdobe[match(latin2, aUnicode)]
## all matches
bLatin2 <- lapply(1:256, function(x) aAdobe[aUnicode == latin2[x]])
format(bLatin2, justify = "none")
```

checkFF

*Check Foreign Function Calls***Description**

Performs checks on calls to compiled code from R code. Currently only checks whether the interface functions such as `.C` and `.Fortran` are called with a "`NativeSymbolInfo`" first argument or with argument `PACKAGE` specified, which is highly recommended to avoid name clashes in foreign function calls.

**Usage**

```
checkFF(package, dir, file, lib.loc = NULL,
        registration = FALSE, check_DUP = FALSE,
        verbose = getOption("verbose"))
```

**Arguments**

|                           |   |
|---------------------------|---|
| <code>package</code>      | a character string naming an installed package. If given, the installed R code of the package is checked.   |
| <code>dir</code>          | a character string specifying the path to a package's root source directory. This should contain the subdirectory 'R' (for R code). Only used if <code>package</code> is not given.   |
| <code>file</code>         | the name of a file containing R code to be checked. Used if neither <code>package</code> nor <code>dir</code> are given.  |
| <code>lib.loc</code>      | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. The specified library trees are used to search for <code>package</code> . |
| <code>registration</code> | a logical. If <code>TRUE</code> , checks the registration information on the call (if available).   |
| <code>check_DUP</code>    | a logical. If <code>TRUE</code> , <code>.C</code> and <code>.Fortran</code> calls with <code>DUP = FALSE</code> are reported.   |
| <code>verbose</code>      | a logical. If <code>TRUE</code> , additional diagnostics are printed (and the result is returned invisibly).  |

**Details**

Note that we can only check if the `name` argument is a symbol or a character string, not what class of object the symbol resolves to at run-time.

If the package has a namespace which contains a `useDynLib` directive, calls in top-level functions in the package are not reported as their symbols will be preferentially looked up in the DLL named in the first `useDynLib` directive.

This checks that calls with `PACKAGE` specified are to the same package, and reports separately those which are in base packages and those which are in other packages (and if those packages are specified in the 'DESCRIPTION' file).

**Value**

An object of class "`checkFF`".

There are `format` and `print` methods to display the information contained in such objects.

**See Also**

[.C](#), [.Fortran](#); [Foreign](#).

**Examples**

```
# order is pretty much random
checkFF(package = "stats", verbose = TRUE)
```

---

checkMD5sums

*Check and Create MD5 Checksum Files*

---

**Description**

checkMD5sums checks the files against a file ‘MD5’.

**Usage**

```
checkMD5sums(package, dir)
```

**Arguments**

|         |  |
|---------|--|
| package | the name of an installed package                             |
| dir     | the path to the top-level directory of an installed package. |

**Details**

The file ‘MD5’ which is created is in a format which can be checked by `md5sum -c MD5` if a suitable command-line version of `md5sum` is available. (For Windows, one is supplied in the bundle at <https://cran.r-project.org/bin/windows/Rtools/>.)

If `dir` is missing, an installed package of name `package` is searched for.

The private function `tools:::installMD5sums` is used to create MD5 files in the Windows build.

**Value**

checkMD5sums returns a logical, NA if there is no ‘MD5’ file to be checked.

**See Also**

[md5sum](#)

checkPoFiles

*Check Translation Files for Inconsistent Format Strings***Description**

These functions compare formats embedded in English messages with translated strings to check for consistency. `checkPoFile` checks one file, while `checkPoFiles` checks all files for specified or all languages.

**Usage**

```
checkPoFile(f, strictPlural = FALSE)
checkPoFiles(language, dir = ".")
```

**Arguments**

|                           |  |
|---------------------------|--|
| <code>f</code>            | a character string giving a single filepath.   |
| <code>strictPlural</code> | whether to compare formats of singular and plural forms in a strict way.   |
| <code>language</code>     | a character string giving a language code, or a ‘ <a href="#">regexp</a> ’ (regular expression), to match languages in <code>dir</code> . Use "" to denote all languages in the <code>dir</code> path. |
| <code>dir</code>          | a path to a directory in which to check files.   |

**Details**

Part of R’s internationalization depends on translations of messages in ‘.po’ files. In these files an ‘English’ message taken from the R sources is followed by a translation into another language. Many of these messages are format strings for C or R [sprintf](#) and related functions. In these cases, the translation must give a compatible format or an error will be generated when the message is displayed.

The rules for compatibility differ between C and R in several ways. C supports several conversions not supported by R, namely `c`, `u`, `p`, `n`. It is allowed in C’s `sprintf()` function to have more arguments than are needed by the format string, but in R the counts must match exactly. R requires types of arguments to match, whereas C will do the display whether it makes sense or not.

These functions compromise on the testing as follows. The additional formats allowed in C are accepted, and all differences in argument type or count are reported. As a consequence some reported differences are not errors.

If the `strictPlural` argument is `TRUE`, then argument lists must agree exactly between singular and plural forms of messages; if `FALSE`, then translations only need to match one or the other of the two forms. When `checkPoFiles` calls `checkPoFile`, the `strictPlural` argument is set to `TRUE` for files with names starting ‘R-’, and to `FALSE` otherwise.

Items marked as ‘fuzzy’ in the ‘.po’ file are not processed (as they are ignored by the message compiler).

If a difference is found, the translated string is checked for variant percent signs (e.g., the wide percent sign `"\uFF05"`). Such signs will not be recognized as format specifiers, and are likely to be errors.

**Value**

Both functions return an object of S3 class `"check_po_files"`. A `print` method is defined for this class to display a report on the differences.

**Author(s)**

Duncan Murdoch

**References**

```
## Not run:
checkPoFiles("de", "/path/to/R/src/directory")

## End(Not run)
```

---

checkRd

---

*Check an Rd Object*

---

**Description**

Check an help file or the output of the `parse_Rd` function.

**Usage**

```
checkRd(Rd, defines = .Platform$OS.type, stages = "render",
        unknownOK = TRUE, listOK = TRUE, ..., def_enc = FALSE)
```

**Arguments**

|           |  |
|-----------|--|
| Rd        | a filename or Rd object to use as input.   |
| defines   | string(s) to use in <code>#ifdef</code> tests.   |
| stages    | at which stage ("build", "install", or "render") should <code>\Sexpr</code> macros be executed? See the notes below.                                   |
| unknownOK | unrecognized macros are treated as errors if <code>FALSE</code> , otherwise warnings.  |
| listOK    | unnecessary non-empty braces (e.g., around text, not as an argument) are treated as errors if <code>FALSE</code> , otherwise warnings (“Lost braces”). |
| ...       | additional parameters to pass to <code>parse_Rd</code> when Rd is a filename. One that is often useful is encoding.                                    |
| def_enc   | logical: has the package declared an encoding, so tests for non-ASCII text are suppressed?   |

## Details

checkRd performs consistency checks on an Rd file, confirming that required sections are present, etc.

It accepts a filename for an Rd file, and will use `parse_Rd` to parse it before applying the checks. If so, warnings from `parse_Rd` are collected, together with those from the internal function `prepare_Rd`, which does the `#ifdef` and `\Sexpr` processing, drops sections that would not be rendered or are duplicated (and should not be) and removes empty sections.

An Rd object is passed through `prepare_Rd`, but it may already have been (and installed Rd objects have).

Warnings are given a ‘level’: those from `prepare_Rd` have level 0. These include

```
\Sexpr expects R code; found ...
Unprocessed ‘stage’ macro from stage-stage \Sexpr
All text must be in a section
Only one tag name section is allowed: the first will be used
docType type is unrecognized
Section name is unrecognized and will be dropped
Dropping empty section name
```

checkRd itself can show

```
7 Tag tag name not recognized
7 Unrecognized format: ...
7 \tabular format must be simple text
7 Unrecognized \tabular format: ...
7 Only n columns allowed in this table
7 Tag tag name is invalid in a block name block
7 \method not valid outside a code block
7 Tag \method is only valid in \usage
7 Tag \dontrun is only valid in \examples
7 Invalid email address: ...
7 Invalid URL: ...
5 \name should not contain !, | or @
5 \item in block name must have non-empty label
3 Empty section tag name
-1 \name should only contain printable ASCII characters
-1 Non-ASCII contents without declared encoding
-1 Non-ASCII contents in second part of \enc
-1 Escaped LaTeX specials: ...
-1-3 Lost braces ...
-3 Tag \ldots is invalid in a code block
-5 \title should not end in a period
```

and variations with `\method` replaced by `\S3method` or `\S4method`, `\dontrun` replaced by `\donttest`, `\dontdiff` or `\dontshow`, and `\title` replaced by `\section` or `\subsection` name. “Lost braces” are uprated to warning level -1 when they match common markup mistakes, e.g., `code{text}` rendered as `codetext` due to the missing backslash escape for the macro name.

Note that both `prepare_Rd` and `checkRd` have tests for an empty section: that in `checkRd` is stricter (essentially that nothing is output).

### Value

This may fail through an R error, but otherwise warnings are collected as returned as an object of class `"checkRd"`, a character vector of messages. This class has a `print` method which only prints unique messages, and has argument `minlevel` that can be used to select only more serious messages. (This is set to `-1` in R CMD `check`.)

Possible fatal errors are those from `!unknownOK` or `!listOK`, from invalid `\if` or `\ifelse` conditions, from running the parser (e.g., a non-existent file, unclosed quoted string, non-ASCII input without a specified encoding, an invalid value for an `\Sexpr` option), or from `prepare_Rd` (multiple `\Rdversion` declarations, invalid `\encoding` or `\docType` or `\name` sections, and missing or duplicate `\name` or `\title` sections), including errors from parsing/running code from `\Sexpr` macros (if covered by stages).

### Author(s)

Duncan Murdoch, Brian Ripley

### See Also

[parse\\_Rd](#), [Rd2HTML](#).

### Examples

```
## parsed Rd from the installed version of _this_ help file
rd <- Rd_db("tools")["checkRd.Rd"]
rd
stopifnot(length(checkRd(rd)) == 0) # there should be no issues

## make up \tabular issues
bad <- r"(\name{bad}\title{bad}\description{\tabular{p}{1 \tab 2}})"
(res <- checkRd(parse_Rd(textConnection(bad))))
stopifnot(length(res) > 0)
```

---

checkRdaFiles

*Report on Details of Saved Images or Re-saves them*

---

### Description

This reports for each of the files produced by `save` the size, if it was saved in ASCII or XDR binary format, and if it was compressed (and if so in what format).

Usually such files have extension `‘.rda’` or `‘.RData’`, hence the name of the function.

### Usage

```
checkRdaFiles(paths)
resaveRdaFiles(paths, compress = c("auto", "gzip", "bzip2", "xz"),
               compression_level, version = NULL)
```

## Arguments

|  |   |
|--|---|
| <code>paths</code>                       | A character vector of paths to save files. If this specifies a single directory, it is taken to refer to all <code>‘.rda’</code> and <code>‘.RData’</code> files in that directory. |
| <code>compress, compression_level</code> | Type and level of compression: see <a href="#">save</a> . Values of <code>compress</code> can be abbreviated.   |
| <code>version</code>                     | The format to be used when re-saving: see <a href="#">save</a> .  |

## Details

`compress = "auto"` asks **R** to choose the compression and ignores `compression_level`. It will try "gzip", "bzip2" and if the "gzip" compressed size is over 10Kb, "xz" and choose the smallest compressed file (but with a 10% bias towards "gzip"). This can be slow.

For back-compatibility, `version = NULL` is interpreted to mean version 2: however version-3 files will only be saved as version 3.

## Value

For `checkRdaFiles`, a data frame with rows names `paths` and columns

|                       |  |
|-----------------------|--|
| <code>size</code>     | numeric: file size in bytes, NA if the file does not exist.  |
| <code>ASCII</code>    | logical: true for <code>save(ASCII = TRUE)</code> , NA if the format is not that of an <b>R</b> save file.   |
| <code>compress</code> | character: type of compression. One of "gzip", "bzip2", "xz", "none" or "unknown" (which means that if this is an <b>R</b> save file it is from a later version of <b>R</b> ). |
| <code>version</code>  | integer: positive with the version(s) of the <a href="#">save()</a> , see there on which versions have been default in which versions of <b>R</b> , and NA for non-Rda files.  |

## Examples

```
## Not run:
## from a package top-level source directory
paths <- sort(Sys.glob(c("data/*.rda", "data/*.RData")))
(res <- checkRdaFiles(paths))
## pick out some that may need attention
bad <- is.na(res$ASCII) | res$ASCII | (res$size > 1e4 & res$compress == "none")
res[bad, ]

## End(Not run)
```

---

checkTnF

*Check R Packages or Code for T/F*

---

## Description

Checks the specified **R** package or code file for occurrences of T or F, and gathers the expression containing these. This is useful as in **R** T and F are just variables which are set to the logicals TRUE and FALSE by default, but are not reserved words and hence can be overwritten by the user. Hence, one should always use TRUE and FALSE for the logicals.

**Usage**

```
checkTnF(package, dir, file, lib.loc = NULL)
```

**Arguments**

|                      |   |
|----------------------|---|
| <code>package</code> | a character string naming an installed package. If given, the installed R code and the examples in the documentation files of the package are checked. R code installed as an image file cannot be checked.   |
| <code>dir</code>     | a character string specifying the path to a package's root source directory. This must contain the subdirectory 'R' (for R code), and should also contain 'man' (for documentation). Only used if <code>package</code> is not given. If used, the R code files and the examples in the documentation files are checked. |
| <code>file</code>    | the name of a file containing R code to be checked. Used if neither <code>package</code> nor <code>dir</code> are given.  |
| <code>lib.loc</code> | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. The specified library trees are used to search for <code>package</code> .   |

**Value**

An object of class "checkTnF" which is a list containing, for each file where occurrences of T or F were found, a list with the expressions containing these occurrences. The names of the list are the corresponding file names.

There is a `print` method for nicely displaying the information contained in such objects.

---

|                             |                                |
|-----------------------------|--------------------------------|
| <code>checkVignettes</code> | <i>Check Package Vignettes</i> |
|-----------------------------|--------------------------------|

---

**Description**

Check all vignettes of a package by running [Sweave](#) (or other custom weave function) and/or [Stangle](#) (or other custom tangle function) on them. All R source code files found after the tangling step are [source](#)d to check whether all code can be executed without errors.

**Usage**

```
checkVignettes(package, dir, lib.loc = NULL,
               tangle = TRUE, weave = TRUE, latex = FALSE,
               workdir = c("tmp", "src", "cur"),
               keepfiles = FALSE)
```

**Arguments**

|                      |   |
|----------------------|---|
| <code>package</code> | a character string naming an installed package. If given, vignette source files are looked for in subdirectory 'doc'.   |
| <code>dir</code>     | a character string specifying the path to a package's root source directory. If given, vignette source files are looked for in subdirectory 'vignettes'.  |
| <code>lib.loc</code> | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. The specified library trees are used to search for <code>package</code> . |

|           |   |
|-----------|---|
| tangle    | Perform a tangle and <a href="#">source</a> the extracted code?   |
| weave     | Perform a weave?  |
| latex     | logical: if weave and latex are TRUE and there is no 'Makefile' in the vignettes directory, run the intermediate '.tex' outputs from weaving through <a href="#">texi2pdf</a> .   |
| workdir   | Directory used as working directory while checking the vignettes. If "tmp" then a temporary directory is created, this is the default. If "src" then the directory containing the vignettes itself is used, if "cur" then the current working directory of R is used. |
| keepfiles | Delete files in the temporary directory? This option is ignored when workdir != "tmp".  |

### Details

This function first uses [pkgVignettes](#) to find the package vignettes, and in particular their vignette engines (see [vignetteEngine](#)).

If `tangle` is true, it then runs [Stangle](#) (or other custom tangle function provided by the engine) to produce (one or more) R code files from each vignette, then [sources](#) each code file in turn.

If `weave` is true, the vignettes are run through [Sweave](#) (or other custom weave function provided by the engine). If `latex` is also true and there is no 'Makefile' in the vignettes directory, [texi2pdf](#) is run on the intermediate '.tex' files from weaving for those vignettes which did not give errors in the previous steps.

### Value

An object of class "checkVignettes", which is a list with the error messages found during the tangle, source, weave and latex steps. There is a `print` method for displaying the information contained in such objects.

---

check\_packages\_in\_dir

*Check Source Packages and Their Reverse Dependencies*

---

### Description

Check source packages in a given directory, optionally with their reverse dependencies.

### Usage

```
check_packages_in_dir(dir,
  pfiles = Sys.glob("*.tar.gz"),
  check_args = character(),
  check_args_db = list(),
  reverse = NULL,
  check_env = character(),
  xvfb = FALSE,
  Ncpus = getOption("Ncpus", 1L),
  clean = TRUE,
  install_args = list(),
```

```

parallel_args = list(),
...)

summarize_check_packages_in_dir_results(dir, all = TRUE,
                                       full = FALSE, ...)
summarize_check_packages_in_dir_timings(dir, all = FALSE,
                                       full = FALSE)
summarize_check_packages_in_dir_depends(dir, all = FALSE,
                                       which = c("Depends",
                                                "Imports",
                                                "LinkingTo"))

check_packages_in_dir_changes(dir, old,
                             outputs = FALSE, sources = FALSE, ...)
check_packages_in_dir_details(dir, logs = NULL, drop_ok = TRUE, ...)

```

### Arguments

|                            |  |
|----------------------------|--|
| <code>dir</code>           | a character string giving the path to the directory with the source <code>‘.tar.gz’</code> files to be checked.  |
| <code>pfiles</code>        | (optional) character vector of tarball files to be checked. Useful for choosing a subset of the <code>‘*.tar.gz’</code> files in <code>dir</code> .  |
| <code>check_args</code>    | a character vector with arguments to be passed to R CMD check, or a list of length two of such character vectors to be used for checking packages and reverse dependencies, respectively.  |
| <code>check_args_db</code> | a named list of character vectors with arguments to be passed to R CMD check, with names the respective package names.   |
| <code>reverse</code>       | a list with names partially matching "repos", "which", or "recursive", giving the repositories to use for locating reverse dependencies (a subset of <code>getOption("repos")</code> , the default), the types of reverse dependencies (default: <code>c("Depends", "Imports", "LinkingTo")</code> , with shorthands "most" and "all" as for <a href="#">package_dependencies</a> ), and indicating whether to also check reverse dependencies of reverse dependencies and so on (default: FALSE), or NULL (default), in which case no reverse dependencies are checked. |
| <code>check_env</code>     | a character vector of name=value strings to set environment variables for checking, or a list of length two of such character vectors to be used for checking packages and reverse dependencies, respectively.   |
| <code>xvfb</code>          | a logical indicating whether to perform checking inside a virtual framebuffer X server (Unix only), or a character vector of Xvfb options for doing so.  |
| <code>Ncpus</code>         | the number of parallel processes to use for parallel installation and checking.  |
| <code>clean</code>         | a logical indicating whether to remove the downloaded reverse dependency sources.  |
| <code>install_args</code>  | list of arguments to be passed to underlying <a href="#">install.packages</a> call.  |
| <code>parallel_args</code> | list of arguments to be passed to underlying calls of <a href="#">parLapply</a> (on Windows) or <a href="#">mclapply</a> (on other OS).  |
| <code>...</code>           | passed to <a href="#">readLines</a> , e.g. for reading log files produced in a different encoding; currently not used by <code>check_packages_in_dir</code> .  |

|                      |  |
|----------------------|--|
| <code>all</code>     | a logical indicating whether to also summarize the reverse dependencies checked.   |
| <code>full</code>    | a logical indicating whether to also give details for checks with non-ok results, or summarize check example timings (if available).   |
| <code>which</code>   | see <a href="#">package_dependencies</a> .   |
| <code>old</code>     | a character string giving the path to the directory of a previous <code>check_packages_in_dir</code> run.  |
| <code>outputs</code> | a logical indicating whether to analyze changes in the outputs of the checks performed, or only (default) the status of the checks.  |
| <code>sources</code> | a logical indicating whether to also investigate the changes in the source files checked (default: FALSE).   |
| <code>logs</code>    | a character vector with the paths of <code>'00check.log'</code> to analyze. Only used if <code>dir</code> was not given.   |
| <code>drop_ok</code> | a logical indicating whether to drop checks with 'ok' status, or a character vector with the 'ok' status tags to drop. The default corresponds to tags 'OK', 'NONE' and 'SKIPPED'. |

## Details

`check_packages_in_dir` allows to conveniently check source package `'.tar.gz'` files in the given directory `dir`, along with their reverse dependencies as controlled by `reverse`.

The "which" component of `reverse` can also be a list, in which case reverse dependencies are obtained for each element of the list and the corresponding element of the "recursive" component of `reverse` (which is recycled as needed).

If needed, the source `'.tar.gz'` files of the reverse dependencies to be checked as well are downloaded into `dir` (and removed at the end if `clean` is true). Next, all packages (additionally) needed for checking are installed to the 'Library' subdirectory of `dir`. Then, all `'.tar.gz'` files are checked using the given arguments and environment variables, with outputs and messages to files in the 'Outputs' subdirectory of `dir`. The `'*.Rcheck'` directories with the check results of the reverse dependencies are renamed by prefixing their base names with `'rdepends_'`.

Results and timings can conveniently be summarized using `summarize_check_packages_in_dir_results` and `summarize_check_packages_in_dir_timings`, respectively.

Installation and checking is performed in parallel if `Ncpus` is greater than one: this will use [mclapply](#) on Unix and [parLapply](#) on Windows.

`check_packages_in_dir` returns an object inheriting from class `"check_packages_in_dir"` which has [print](#) and [summary](#) methods.

`check_packages_in_dir_changes` allows to analyze the effect of changing (some of) the sources. With `dir` and `old` the paths to the directories with the new and old sources, respectively, and the corresponding check results, possible changes in the check results can conveniently be analyzed as controlled via options `outputs` and `sources`. The changes object returned can be subscripted according to change in severity from the old to the new results by using one of `"=="`, `"!="`, `"<"`, `"<="`, `">"` or `">="` as row index.

`check_packages_in_dir_details` analyzes check log files to obtain check details as a data frame which can be used for further processing, providing check name, status and output for every check performed and not dropped according to status tag (via variables `Check`, `Status` and `Output`, respectively).

Environment variable `_R_CHECK_ELAPSED_TIMEOUT_` can be used to set a limit on the elapsed time of each `check` run. See the ‘R Internals’ manual for how the value is interpreted and for other environment variables which can be used for finer-grained control on timeouts within a `check` run.

### Note

This functionality is still experimental: interfaces may change in future versions.

### Examples

```
## Not run:
## Check packages in dir without reverse dependencies:
check_packages_in_dir(dir)
## Check packages in dir and their reverse dependencies using the
## defaults (all repositories in getOption("repos"), all "strong"
## reverse dependencies, no recursive reverse dependencies):
check_packages_in_dir(dir, reverse = list())
## Check packages in dir with their reverse dependencies from CRAN,
## using all strong reverse dependencies and reverse suggests:
check_packages_in_dir(dir,
                      reverse = list(repos = getOption("repos")["CRAN"],
                                     which = "most"))
## Check packages in dir with their reverse dependencies from CRAN,
## using '--as-cran' for the former but not the latter:
check_packages_in_dir(dir,
                      check_args = c("--as-cran", ""),
                      reverse = list(repos = getOption("repos")["CRAN"]))

## End(Not run)
```

---

codoc

*Check Code/Documentation Consistency*

---

### Description

Find inconsistencies between actual and documented ‘structure’ of R objects in a package. `codoc` compares names and optionally also corresponding positions and default values of the arguments of functions. `codocClasses` and `codocData` compare slot names of S4 classes and variable names of data sets, respectively.

### Usage

```
codoc(package, dir, lib.loc = NULL,
      use.values = NULL, verbose = getOption("verbose"))
codocClasses(package, lib.loc = NULL)
codocData(package, lib.loc = NULL)
```

### Arguments

|                      |  |
|----------------------|--|
| <code>package</code> | a character string naming an installed package.  |
| <code>dir</code>     | a character string specifying the path to a package’s root source directory. This must contain the subdirectories ‘man’ with R documentation sources (in Rd format) and ‘R’ with R code. Only used if <code>package</code> is not given. |

|                         |   |
|-------------------------|---|
| <code>lib.loc</code>    | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. The specified library trees are used to search for package. |
| <code>use.values</code> | if <code>FALSE</code> , do not use function default values when comparing code and docs. Otherwise, compare <i>all</i> default values if <code>TRUE</code> , and only the ones documented in the usage otherwise (default).   |
| <code>verbose</code>    | a logical. If <code>TRUE</code> , additional diagnostics are printed.   |

## Details

The purpose of `codoc` is to check whether the documented usage of function objects agrees with their formal arguments as defined in the R code. This is not always straightforward, in particular as the usage information for methods to generic functions often employs the name of the generic rather than the method.

The following algorithm is used. If an installed package is used, it is loaded (unless it is the **base** package), after possibly detaching an already loaded version of the package. Otherwise, if the sources are used, the R code files of the package are collected and sourced in a new environment. Then, the usage sections of the Rd files are extracted and parsed ‘as much as possible’ to give the formals documented. For interpreted functions in the code environment, the formals are compared between code and documentation according to the values of the argument `use.values`.

If a package has a namespace both exported and unexported objects are checked, as well as registered S3 methods. (In the unlikely event of differences the order is exported objects in the package, registered S3 methods and finally objects in the namespace and only the first found is checked.)

Currently, the R documentation format has no high-level markup for the basic ‘structure’ of classes and data sets (similar to the usage sections for function synopses). Variable names for data frames in documentation objects obtained by suitably editing ‘templates’ created by `prompt` are recognized by `codocData` and used provided that the documentation object is for a single data frame (i.e., only has one alias). `codocClasses` analogously handles slot names for classes in documentation objects obtained by editing shells created by `promptClass`.

Help files named ‘*pkgname*-defunct.Rd’ for the appropriate *pkgname* are checked more loosely, as they may have undocumented arguments.

## Value

`codoc` returns an object of class “`codoc`”. Currently, this is a list which, for each Rd object in the package where an inconsistency was found, contains an element with a list of the mismatches (which in turn are lists with elements `code` and `docs`, giving the corresponding arguments obtained from the function’s code and documented usage).

`codocClasses` and `codocData` return objects of class “`codocClasses`” and “`codocData`”, respectively, with a structure similar to class “`codoc`”.

There are `print` methods for nicely displaying the information contained in such objects.

## Note

The default for `use.values` has been changed from `FALSE` to `NULL`, for R versions 1.9.0 and later.

## See Also

[undoc](#), [QC](#)

## Description

Re-save PDF files (especially vignettes) more compactly. Support function for R CMD build --compact-vignettes.

## Usage

```
compactPDF(paths,
  qpdf = Sys.which(Sys.getenv("R_QPDF", "qpdf")),
  gs_cmd = Sys.getenv("R_GSCMD", ""),
  gs_quality = Sys.getenv("GS_QUALITY", "none"),
  gs_extras = character(),
  verbose = FALSE)

## S3 method for class 'compactPDF'
format(x, ratio = 0.9, diff = 1e4, ...)
```

## Arguments

|             |  |
|-------------|--|
| paths       | A character vector of paths to PDF files, or a length-one character vector naming a directory, when all ‘.pdf’ files in that directory will be used.   |
| qpdf        | Character string giving the path to the qpdf command. If empty, qpdf will not be used.   |
| gs_cmd      | Character string giving the path to the GhostScript executable, if that is to be used. On Windows this is the path to ‘gswin32c.exe’ or ‘gswin64c.exe’. If "" (the default), the function will try to find a platform-specific path to GhostScript where required. |
| gs_quality  | A character string indicating the quality required: the options are "none" (so GhostScript is not used), "printer" (300dpi), "ebook" (150dpi) and "screen" (72dpi). Can be abbreviated.  |
| gs_extras   | An optional character vector of further options to be passed to GhostScript.   |
| verbose     | <code>logical</code> or non-negative integer indicating if and how much of the compression utilities’ output should be shown.  |
| x           | An object of class "compactPDF".   |
| ratio, diff | Limits for reporting: files are only reported whose sizes are reduced both by a factor of <code>ratio</code> and by <code>diff</code> bytes.   |
| ...         | Further arguments to be passed to or from other methods.   |

## Details

This by default makes use of qpdf, available from <https://qpdf.sourceforge.io/> (including as a Windows binary) and included with the CRAN macOS distribution of R. If `gs_cmd` is non-empty and `gs_quality != "none"`, GhostScript will be used first, then qpdf if it is available. If `gs_quality != "none"` and `gs_cmd` is "", an attempt will be made to find a GhostScript executable.

`qpdf` and/or `gs_cmd` are run on all PDF files found, and those which are reduced in size by at least 10% and 10Kb are replaced.

The strategy of our use of `qpdf` is to (losslessly) compress both PDF streams and objects. GhostScript compresses streams and more (including downsampling and compressing embedded images) and consequently is much slower and may lose quality (but can also produce much smaller PDF files). However, quality "ebook" is perfectly adequate for screen viewing and printing on laser printers.

Where PDF files are changed they will become PDF version 1.5 files: these have been supported by Acrobat Reader since version 6 in 2003, so this is very unlikely to cause difficulties.

Stream compression is what most often has large gains. Most PDF documents are generated with object compression, but this does not seem to be the default for MiKTeX's `pdflatex`. For some PDF files (and especially package vignettes), using GhostScript can dramatically reduce the space taken by embedded images (often screenshots).

Where both GhostScript and `qpdf` are selected (when `gs_quality != "none"` and both executables are found), they are run in that order and the size reductions apply to the total compression achieved.

### Value

An object of class `c("compactPDF", "data.frame")`. This has two columns, the old and new sizes in bytes for the files that were changed.

There are `format` and `print` methods: the latter passes `...` to the `format` method, so will accept `ratio` and `diff` arguments.

### Note

The external tools used may change in future releases.

Frequently, updates to GhostScript have produced better compression (up to several times better), so if possible use the latest version available.

### See Also

[resaveRdaFiles](#).

For other tools to compact PDF files, see the 'Writing R Extensions' manual.

### Description

Tools for obtaining information about current packages in the CRAN package repository, and their check status.

## Usage

```
CRAN_package_db()

CRAN_check_results(flavors = NULL)
CRAN_check_details(flavors = NULL)
CRAN_check_issues()
summarize_CRAN_check_status(packages,
                             results = NULL,
                             details = NULL,
                             issues = NULL)
```

## Arguments

|                       |  |
|-----------------------|--|
| <code>packages</code> | a character vector of package names.   |
| <code>flavors</code>  | a character vector of CRAN check flavor names, or <code>NULL</code> (default), corresponding to all available flavors. |
| <code>results</code>  | the return value of <code>CRAN_check_results()</code> (default), or a subset of this.                                  |
| <code>details</code>  | the return value of <code>CRAN_check_details()</code> (default), or a subset of this.                                  |
| <code>issues</code>   | the return value of <code>CRAN_check_issues()</code> (default), or a subset of this.                                   |

## Details

`CRAN_package_db()` returns a data frame with character columns containing most ‘DESCRIPTION’ metadata for the current packages in the CRAN package repository, including in particular the Description and Maintainer information not provided by `utils::available.packages()`.

`CRAN_check_results()` returns a data frame with the basic CRAN package check results including timings, with columns `Package`, `Flavor` and `Status` giving the package name, check flavor, and overall check status, respectively.

`CRAN_check_details()` returns a data frame inheriting from class `"check_details"` (which has useful `print` and `format` methods) with details on the check results, providing check name, status and output for every non-OK check (via columns `Check`, `Status` and `Output`, respectively). Packages with all-OK checks are indicated via a `* Check` wildcard name and OK Status.

`CRAN_check_issues()` returns a character frame with additional check issues (including the memory-access check results made available from <https://www.stats.ox.ac.uk/pub/bdr/memtests/>) as a character frame with variables `Package`, `Version`, `kind` (an identifier for the issue) and `href` (a URL with information on the issue).

## Value

See ‘Details’. Note that the results are collated on CRAN: currently this is done in a locale which sorts `aAbB....`.

## Which CRAN?

The main functions access a CRAN mirror specified by the environment variable `R_CRAN_WEB`, defaulting to one specified in the `"repos"` option. Otherwise the entry in the ‘repositories’ file (see [setRepositories](#)) is used: if that specifies ‘@CRAN@’ (the default) or does not contain an entry for CRAN then <https://CRAN.R-project.org> is used.

The mirror to be used is reported by `utils::findCRANmirror("web")`.

Note that these functions access parts of CRAN under ‘web/contrib’ and ‘web/packages’ so if you have specified a mirror of just ‘src/contrib’ for installing packages you will need to set `R_CRAN_WEB` to point to a full mirror.

Internal functions `CRAN_aliases_db`, `CRAN_archive_db`, `CRAN_current_db` and `CRAN_rdxrefs_db` (used by R CMD check) use `R_CRAN_SRC` rather than `R_CRAN_WEB`.

## Examples

```
## This can be rather slow with a non-local CRAN mirror
## and might fail (slowly) without Internet access in that case.

set.seed(11) # but the packages chosen will change as soon as CRAN does.
pdb <- CRAN_package_db()
dim(pdb)
## DESCRIPTION fields included:
colnames(pdb)
## Summarize publication dates:
summary(as.Date(pdb$Published))
## Summarize numbers of packages according to maintainer:
summary(lengths(split(pdb$Package, pdb$Maintainer)))
## Packages with 'LASSO' in their Description:
pdb$Package[grepl("LASSO", pdb$Description)]

results <- CRAN_check_results()
## Available variables:

## Tabulate checks according to their status:
tab <- with(details, table(Check, Status))
## Inspect some installation problems:
bad <- subset(details,
              ((Check == "whether package can be installed") &
               (Status != "OK")))
## Show a random sample of up to 6
head(bad[sample(seq_len(NROW(bad)), NROW(bad)), ])

issues <- CRAN_check_issues()
head(issues)
## Show counts of issues according to kind:
table(issues[, "kind"])

## Summarize CRAN check status for 10 randomly-selected packages
## (reusing the information already read in):
pos <- sample(seq_len(NROW(pdb)), 10L)
summarize_CRAN_check_status(pdb[pos, "Package"],
                           results, details, issues)
```

delimMatch

*Delimited Pattern Matching***Description**

Match delimited substrings in a character vector, with proper nesting.

**Usage**

```
delimMatch(x, delim = c("{", "}"), syntax = "Rd")
```

**Arguments**

|                     |   |
|---------------------|---|
| <code>x</code>      | a character vector.   |
| <code>delim</code>  | a character vector of length 2 giving the start and end delimiters. Future versions might allow for arbitrary regular expressions.  |
| <code>syntax</code> | currently, always the string "Rd" indicating Rd syntax (i.e., ‘%’ starts a comment extending till the end of the line, and ‘\’ escapes). Future versions might know about other syntax, perhaps via ‘syntax tables’ allowing to flexibly specify comment, escape, and quote characters. |

**Value**

An integer vector of the same length as `x` giving the starting position (in characters) of the first match, or `-1` if there is none, with attribute `"match.length"` giving the length (in characters) of the matched text (or `-1` for no match).

**See Also**

[regexpr](#) for ‘simple’ pattern matching.

**Examples**

```
x <- c("\\value{foo}", "function(bar)")
delimMatch(x)
delimMatch(x, c("(", ")"))
```

dependsOnPkgs

*Find Reverse Dependencies***Description**

Find ‘reverse’ dependencies of packages, that is those packages which depend on this one, and (optionally) so on recursively.

**Usage**

```
dependsOnPkgs(pkgs,
  dependencies = "strong",
  recursive = TRUE, lib.loc = NULL,
  installed =
    utils::installed.packages(lib.loc, fields = "Enhances"))
```

**Arguments**

|                           |   |
|---------------------------|---|
| <code>pkgs</code>         | a character vector of package names.  |
| <code>dependencies</code> | a character vector listing the types of dependencies, a subset of <code>c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances")</code> . Character string "all" is shorthand for that vector, character string "most" for the same vector without "Enhances", character string "strong" (default) for the first three elements of that vector. |
| <code>recursive</code>    | logical: should reverse dependencies of reverse dependencies (and so on) be included?   |
| <code>lib.loc</code>      | a character vector of R library trees, or NULL for all known trees (see <code>.libPaths</code> ).   |
| <code>installed</code>    | a result of calling <code>installed.packages</code> .   |

**Value**

A character vector of package names, which does not include any from `pkgs`.

**See Also**

`package_dependencies()` to get the regular ("forward") dependencies of a package.

**Examples**

```
## there are few dependencies in a vanilla R installation:
## lattice may not be installed
dependsOnPkgs("lattice")
```

---

encoded\_text\_to\_latex

*Translate non-ASCII Text to LaTeX Escapes*

---

**Description**

Translate non-ASCII characters in text to LaTeX escape sequences.

**Usage**

```
encoded_text_to_latex(x,
                      encoding = c("latin1", "latin2", "latin9",
                                   "UTF-8", "utf8"))
```

**Arguments**

|                       |   |
|-----------------------|---|
| <code>x</code>        | a character vector.   |
| <code>encoding</code> | the encoding to be assumed. "latin9" is officially ISO-8859-15 or Latin-9, but known as latin9 to LaTeX's inputenc package. |

## Details

Non-ASCII characters in `x` are replaced by an appropriate LaTeX escape sequence, or ‘?’ if there is no appropriate sequence.

Even if there is an appropriate sequence, it may not be supported by the font in use. Hyphen is mapped to ‘\‑’.

## Value

A character vector of the same length as `x`.

## See Also

[iconv](#)

## Examples

```
x <- "fran\xE7ais"
encoded_text_to_latex(x, "latin1")
## Not run:
## create a tex file to show the upper half of 8-bit charsets
x <- rawToChar(as.raw(160:255), multiple = TRUE)
(x <- matrix(x, ncol = 16, byrow = TRUE))
xx <- x
xx[] <- encoded_text_to_latex(x, "latin1") # or latin2 or latin9
xx <- apply(xx, 1, paste, collapse = "&")
con <- file("test-encoding.tex", "w")
header <- c(
  "\\documentclass{article}",
  "\\usepackage[T1]{fontenc}",
  "\\usepackage{Rd}",
  "\\begin{document}",
  "\\HeaderA{test}{}{test}",
  "\\begin{Details}\\relax",
  "\\Tabular{cccccccccccccc}{")
trailer <- c(")", "\\end{Details}", "\\end{document}")
writeLines(header, con)
writeLines(paste0(xx, "\\\\"), con)
writeLines(trailer, con)
close(con)
## and some UTF_8 chars
x <- intToUtf8(as.integer(
  c(160:383, 0x0192, 0x02C6, 0x02C7, 0x02CA, 0x02D8,
    0x02D9, 0x02DD, 0x200C, 0x2018, 0x2019, 0x201C,
    0x201D, 0x2020, 0x2022, 0x2026, 0x20AC)),
  multiple = TRUE)
x <- matrix(x, ncol = 16, byrow = TRUE)
xx <- x
xx[] <- encoded_text_to_latex(x, "UTF-8")
xx <- apply(xx, 1, paste, collapse = "&")
con <- file("test-utf8.tex", "w")
writeLines(header, con)
writeLines(paste(xx, "\\\\"), sep = ""), con)
writeLines(trailer, con)
close(con)

## End(Not run)
```

fileutils

*File Utilities***Description**

Utilities for listing files, and manipulating file paths.

**Usage**

```
file_ext(x)
file_path_as_absolute(x)
file_path_sans_ext(x, compression = FALSE)

list_files_with_exts(dir, exts, all.files = FALSE,
                     full.names = TRUE)
list_files_with_type(dir, type, all.files = FALSE,
                     full.names = TRUE, OS_subdirs = .OSType())
```

**Arguments**

|                          |  |
|--------------------------|--|
| <code>x</code>           | character vector giving file paths.  |
| <code>compression</code> | logical: should compression extension <code>‘.gz’</code> , <code>‘.bz2’</code> or <code>‘.xz’</code> be removed first?   |
| <code>dir</code>         | a character string with the path name to a directory.  |
| <code>exts</code>        | a character vector of possible file extensions (excluding the leading dot).  |
| <code>all.files</code>   | a logical. If <code>FALSE</code> (default), only visible files are considered; if <code>TRUE</code> , all files are used.  |
| <code>full.names</code>  | a logical indicating whether the full paths of the files found are returned (default), or just the file names.   |
| <code>type</code>        | a character string giving the ‘type’ of the files to be listed, as characterized by their extensions. Currently, possible values are <code>"code"</code> (R code), <code>"data"</code> (data sets), <code>"demo"</code> (demos), <code>"docs"</code> (R documentation), and <code>"vignette"</code> (vignettes). |
| <code>OS_subdirs</code>  | a character vector with the names of OS-specific subdirectories to possibly include in the listing of R code and documentation files. By default, the value of the environment variable <code>R_OSTYPE</code> , or if this is empty, the value of <code>.Platform\$OS.type</code> , is used.                     |

**Details**

`file_ext` returns the file (name) extensions (excluding the leading dot). (Only purely alphanumeric extensions are recognized.)

`file_path_as_absolute` turns a possibly relative file path absolute, performing tilde expansion if necessary. This is a wrapper for `normalizePath`. Currently, `x` must be a single existing path.

`file_path_sans_ext` returns the file paths without extensions (and the leading dot). (Only purely alphanumeric extensions are recognized.)

`list_files_with_exts` returns the paths or names of the files in directory `dir` with extension matching one of the elements of `exts`. Note that by default, full paths are returned, and that only visible files are used.

`list_files_with_type` returns the paths of the files in `dir` of the given ‘type’, as determined by the extensions recognized by R. When listing R code and documentation files, files in OS-specific subdirectories are included if present according to the value of `OS_subdirs`. Note that by default, full paths are returned, and that only visible files are used.

### See Also

`file.path`, `file.info`, `list.files`

### Examples

```
dir <- file.path(R.home(), "library", "stats")
list_files_with_exts(file.path(dir, "demo"), "R")
list_files_with_type(file.path(dir, "demo"), "demo") # the same
file_path_sans_ext(list.files(file.path(R.home("modules"))))
```

---

find\_gs\_cmd

*Find a GhostScript Executable*

---

### Description

Find a GhostScript executable in a cross-platform way.

### Usage

```
find_gs_cmd(gs_cmd = "")
```

### Arguments

`gs_cmd`                      The name, full or partial path of a GhostScript executable.

### Details

The details differ by platform.

On a Unix-alike, the GhostScript executable is usually called `gs`. The name (and possibly path) of the command is taken first from argument `gs_cmd` then from the environment variable `R_GSCMD` and default `gs`. This is then looked for on the system path and the value returned if a match is found.

On Windows, the name of the command is taken from argument `gs_cmd` then from the environment variables `R_GSCMD` and `GSC`. If neither of those produces a suitable command name, `gswin64c` and `gswin32c` are tried in turn. In all cases the command is looked for on the system `PATH`.

Note that on Windows (and some other OSes) there are separate GhostScript executables to display Postscript/PDF files and to manipulate them: this function looks for the latter.

### Value

A character string giving the full path to a GhostScript executable if one was found, otherwise an empty string.

**Examples**

```
## Not run:
## Suppose a Solaris system has GhostScript 9.00 on the path and
## 9.07 in /opt/csw/bin. Then one might set
Sys.setenv(R_GSCMD = "/opt/csw/bin/gs")

## End(Not run)
```

---

|                 |   |
|-----------------|---|
| getVignetteInfo | <i>Get Information on Installed Vignettes</i> |
|-----------------|---|

---

**Description**

This function gets information on installed vignettes.

**Usage**

```
getVignetteInfo(package = NULL, lib.loc = NULL, all = TRUE)
```

**Arguments**

|         |  |
|---------|--|
| package | Which package to look in, or NULL for all packages.                  |
| lib.loc | Which library to look in.  |
| all     | Whether to search all installed packages, or just attached packages. |

**Value**

A matrix with columns

|         |   |
|---------|---|
| Package | the name of the package                         |
| Dir     | the directory where the package is installed    |
| Topic   | the name of the vignette                        |
| File    | the base filename of the source of the vignette |
| Title   | the title of the vignette                       |
| R       | the tangled R source from the vignette          |
| PDF     | the PDF or HTML file for display                |

**Note**

The last column of the result is named `PDF` for historical reasons, but it may contain a filename of a PDF or HTML document.

**See Also**

[pkgVignettes](#) is a similar function that can work on an uninstalled package.

**Examples**

```
getVignetteInfo("grid")
```

## Description

This function generates the standard HTML header used on R help pages.

## Usage

```
HTMLheader(title = "R", logo = TRUE, up = NULL,
            top = file.path(Rhome, "doc/html/index.html"),
            Rhome = "",
            css = file.path(Rhome, "doc/html/R.css"),
            headerTitle = paste("R:", title),
            outputEncoding = "UTF-8")
```

## Arguments

|                             |   |
|-----------------------------|---|
| <code>title</code>          | The title to display and use in the HTML headers. Should have had any HTML escaping already done. |
| <code>logo</code>           | Whether to display the R logo after the title.  |
| <code>up</code>             | Which page (if any) to link to on the “up” button.  |
| <code>top</code>            | Which page (if any) to link to on the “top” button.   |
| <code>Rhome</code>          | A <b>relative</b> path to the R home directory. See the ‘Details’.                                |
| <code>css</code>            | The relative URL for the Cascading Style Sheet.   |
| <code>headerTitle</code>    | The title used in the headers.  |
| <code>outputEncoding</code> | The declared encoding for the whole page.   |

## Details

The `up` and `top` links should be relative to the current page. The `Rhome` path default works with dynamic help; for static help, a relative path (e.g., `../..`) to it should be used.

## Value

A character vector containing the lines of an HTML header which can be used to start a page in the R help system.

## Examples

```
cat(HTMLheader("This is a sample header"), sep="\n")
```

HTMLlinks

*Collect HTML Links from Package Documentation***Description**

Compute relative file paths for URLs to other package's installed HTML documentation.

**Usage**

```
findHTMLlinks(pkgDir = "", lib.loc = NULL, level = 0:2)
```

**Arguments**

|                      |   |
|----------------------|---|
| <code>pkgDir</code>  | the top-level directory of an installed package. The default indicates no package.                                    |
| <code>lib.loc</code> | character vector describing the location of R library trees to scan: the default indicates <code>.libPaths()</code> . |
| <code>level</code>   | Which level(s) to include.  |

**Details**

`findHTMLlinks` tries to resolve links from one help page to another. It uses in decreasing priority

- The package in `pkgDir`: this is used when converting HTML help for that package (level 0).
- The base and recommended packages (level 1).
- Other packages found in the library trees specified by `lib.loc` in the order of the trees and alphabetically within a library tree (level 2).

**Value**

A named character vector of file paths, relative to the 'html' directory of an installed package. So these are of the form `"../.. /somepkg/html/sometopic.html"`.

**Author(s)**

Duncan Murdoch, Brian Ripley

loadRdMacros

*Load User-defined Rd Help System Macros***Description**

Loads macros from an '.Rd' file, or from several '.Rd' files contained in a package.

**Usage**

```
loadRdMacros(file, macros = TRUE)
loadPkgRdMacros(pkgdir, macros = NULL)
```

**Arguments**

|                     |   |
|---------------------|---|
| <code>file</code>   | A file in Rd format containing macro definitions.   |
| <code>macros</code> | optionally, a previous set of macro definitions, in the format expected by the <a href="#">parse_Rd</a> <code>macros</code> argument. <code>loadPkgRdMacros</code> loads the system Rd macros by default. |
| <code>pkgdir</code> | The base directory of a source package or an installed package.   |

**Details**

The Rd files parsed by these functions should contain only macro definitions; a warning will be issued if anything else other than comments or white space is found.

The `macros` argument may be a filename of a base set of macros, or the result of a previous call to `loadRdMacros` or `loadPkgRdMacros` in the same session. These results should be assumed to be valid only within the current session.

The `loadPkgRdMacros` function first looks for an "RdMacros" entry in the package 'DESCRIPTION' file. If present, it should contain a comma-separated list of other package names; their macros will be loaded before those of the current package. It will then look in the current package for '.Rd' files in the 'man/macros' or 'help/macros' subdirectories, and load those.

**Value**

These functions each return an environment containing objects with the names of the newly defined macros from the last file processed. The parent environment will be macros from the previous file, and so on. The first file processed will have `emptyenv()` as its parent.

**Author(s)**

Duncan Murdoch

**References**

See the 'Writing R Extensions' manual for the syntax of Rd files, or <https://developer.r-project.org/parseRd.pdf> for a technical discussion.

[parse\\_Rd](#)

**Examples**

```
f <- tempfile()
writeLines(r"(
\\newcommand{\\Rlogo}{
  \\if{html}{\\figure{Rlogo.svg}{options: width=100 alt="R logo"}}
  \\if{latex}{\\figure{Rlogo.pdf}{options: width=0.5in}}
}
)", f)
m <- loadRdMacros(f)
ls(m)
ls(parent.env(m))
ls(parent.env(parent.env(m)))
parse_Rd(textConnection(r"(\\Rlogo)"), fragment = TRUE, macros = m)
```

---

makevars

*User and Site Compilation Variables*

---

**Description**

Determine the location of the user and site specific ‘Makevars’ files for customizing package compilation.

**Usage**

```
makevars_user()
makevars_site()
```

**Details**

Package maintainers can use these functions to employ user and site specific compilation settings also for compilations not using R’s mechanisms (in particular, custom compilations in subdirectories of ‘src’), e.g., by adding configure code calling R with `cat(tools::makevars_user())` or `cat(tools::makevars_site())`, and if non-empty passing this with ‘-f’ to custom Make invocations.

**Value**

A character string with the path to the user or site specific ‘Makevars’ file, or an empty character vector if there is no such file.

**See Also**

Section ‘Customizing package compilation’ in the ‘R Installation and Administration’ manual.

**Examples**

```
makevars_user()
makevars_site()
```

---

make\_translations\_pkg

*Package the Current Translations in the R Sources*

---

**Description**

A utility for R Core members to prepare a package of updated translations.

**Usage**

```
make_translations_pkg(srcdir, outDir = ".", append = "-1")
```

**Arguments**

|        |   |
|--------|---|
| srcdir | The R source directory.   |
| outDir | The directory into which to place the prepared package.                                   |
| append | The suffix for the package version number, e.g. ‘3.0.0-1’ will be the default in R 3.0.0. |

**Details**

This extracts the translations in a current R source distribution and packages them as a source package called **translations** which can be distributed on CRAN and installed by `update.packages`. This allows e.g. the translations shipped in R 3.x.y to be updated to those currently in ‘R-patched’, even by a user without administrative privileges.

The package has a ‘Depends’ field which restricts it to versions ‘3.x.\*’ for a single x.

---

|                  |  |
|------------------|--|
| matchConcordance | <i>Concordance between source and target lines</i> |
|------------------|--|

---

**Description**

The Rd parser records locations in ‘.Rd’ files from which components of the file are read. Output generators `Rd2HTML` and `Rd2latex` can output information about these locations as “concordances” between source and output lines.

`matchConcordance` converts from output locations to source locations. The “Rconcordance” method of `as.character` produces strings to embed in output files, and the default method of `as.Rconcordance` converts these back to objects that can be interpreted by `matchConcordance`.

**Usage**

```
matchConcordance(linenum, concordance)
## S3 method for class 'Rconcordance'
as.character(x, targetfile = "", ...)
as.Rconcordance(x, ...)
followConcordance(concordance, prevConcordance)
```

**Arguments**

|                 |   |
|-----------------|---|
| linenum         | One or more line numbers being queried.   |
| concordance     | The concordance data for the file containing the lines: an object of class “Rconcordance”.  |
| prevConcordance | A concordance object retrieved from the current file.   |
| targetfile      | The output filename.  |
| x               | The object to convert: for <code>as.character</code> , an “Rconcordance” object; for <code>as.concordance</code> , a character vector which contains <code>as.character</code> output, typically in comments. |
| ...             | Further arguments passed to other methods.  |

## Details

The correspondence between target lines and source lines in Rd file conversion is not one to one. Often a single source line can lead to the generation of multiple output lines, and sometimes more than one source line triggers output on the same output line.

`matchConcordance` converts from target lines to source lines. This can be used to help in understanding how particular output lines depend on the source, e.g. when an error is found in the output file. When more than one line contributes to the output, the last one will be returned.

The `"Rconcordance"` method of `as.character` converts a concordance object to strings suitable for embedding (e.g. in comments) in an output file.

The default method of `as.Rconcordance` searches for strings matching the pattern of `as.character.Rconcordance` output, then converts those lines back to a single concordance.

`followConcordance` is used when a file is transformed more than once. The first transformation records a concordance in the file which is read as `prevConcordance`. `followConcordance` chains this with the current concordance, relating the final result to the original source.

There are 3 kinds of objects used to hold concordances.

Objects of class `"activeConcordance"` are internal to **tools**; they are used by `Rd2HTML` and `Rd2latex` while building the output file and saving links to the source file.

Objects of class `"Rconcordance"` are visible to users. They are list objects with the following three fields:

`offset` The number of lines of output before the first one corresponding to this concordance.

`srcLine` For each line of output after the offset, the corresponding input file line number. There may be more lines of output than the length of `srcLine`, in which case nothing can be inferred about the source of those lines.

`srcFile` A vector of filenames of length 1 or the same length as `srcLine` giving the source file(s) for each output line.

Concordance strings are produced by the `"Rconcordance"` method of `as.character`; they are simply character vectors encoding the concordance data. The default method of the `as.concordance` generic function converts them to `"Rconcordance"` objects.

## Value

`matchConcordance` returns a character array with one row per input `linenum` entry and two columns, `"srcFile"` and `"srcLine"`.

For the `"Rconcordance"` method of `as.character`, a character vector used (e.g. in [Sweave](#)) to embed the concordance in a file.

For `as.concordance`, an `"Rconcordance"` object, or `NULL` if no concordance strings are found.

Duncan Murdoch

## See Also

[Rd2HTML](#), [Rd2latex](#)

---

md5sum*Compute MD5 Checksums*

---

## Description

Compute the 32-byte MD5 hashes of one or more files.

## Usage

```
md5sum(files)
```

## Arguments

`files` character. The paths of file(s) whose contents are to be hashed.

## Details

A MD5 ‘hash’ or ‘checksum’ or ‘message digest’ is a 128-bit summary of the file contents represented by 32 hexadecimal digits. Files with different MD5 sums are different: only very exceptionally (and usually with the intent to deceive) are those with the same sums different.

On Windows all files are read in binary mode (as the `md5sum` utilities there do): on other OSes the files are read in the default mode (almost always text mode where there is more than one).

MD5 sums are used as a check that R packages have been unpacked correctly and not subsequently accidentally modified.

## Value

A character vector of the same length as `files`, with names equal to `files` (possibly expanded). The elements will be NA for non-existent or unreadable files, otherwise a 32-character string of hexadecimal digits.

## Source

The underlying C code was written by Ulrich Drepper and extracted from a 2001 release of `glibc`.

```
as.vector(md5sum(dir(R.home(), pattern = "^COPY", full.names = TRUE)))
```

---

`package_dependencies`*Computations on the Dependency Hierarchy of Packages*

---

## Description

Find (recursively) dependencies or reverse dependencies of packages.

## Usage

```
package_dependencies(packages = NULL, db = NULL, which = "strong",
  recursive = FALSE, reverse = FALSE,
  verbose = getOption("verbose"))
```

## Arguments

|                        |  |
|------------------------|--|
| <code>packages</code>  | a character vector of package names.   |
| <code>db</code>        | character matrix as from <code>available.packages()</code> (with the default <code>NULL</code> the results of this call) or data frame variants thereof. Alternatively, a package database like the one available from <a href="https://cran.r-project.org/web/packages/packages.rds">https://cran.r-project.org/web/packages/packages.rds</a> .   |
| <code>which</code>     | a character vector listing the types of dependencies, a subset of <code>c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances")</code> . Character string <code>"all"</code> is shorthand for that vector, character string <code>"most"</code> for the same vector without <code>"Enhances"</code> , character string <code>"strong"</code> (default) for the first three elements of that vector. |
| <code>recursive</code> | a logical indicating whether (reverse) dependencies of (reverse) dependencies (and so on) should be included, or a character vector like <code>which</code> indicating the type of (reverse) dependencies to be added recursively.   |
| <code>reverse</code>   | logical: if <code>FALSE</code> (default), regular dependencies are calculated, otherwise reverse dependencies.   |
| <code>verbose</code>   | logical indicating if output should monitor the package search cycles.   |

## Value

Named list with one element for each package in argument `packages`, each consists of a character vector naming the (recursive) (reverse) dependencies of that package.

For given packages which are not found in the `db`, `NULL` entries are returned, as opposed to `character(0)` entries which indicate no dependencies.

## See Also

[dependsOnPkgs](#).

## Examples

```
myPkgs <- c("MASS", "Matrix", "KernSmooth", "class", "cluster", "codetools")
pdb <- available.packages(repos = findCRANmirror("web"))
system.time(
  depl <- package_dependencies(myPkgs, db = pdb) # all arguments at default
) # very fast
utils::str(depl, vec.len=10)

system.time( ## reverse dependencies, recursively --- takes much longer:
  deps <- package_dependencies(myPkgs, db = pdb, which = "most",
                             recursive = TRUE, reverse = TRUE)
) # seen ~ 10 seconds

lengths(deps) # 2020-05-03: all are 16053, but codetools with 16057

## install.packages(dependencies = TRUE) installs 'most' dependencies
## and the strong recursive dependencies of these: these dependencies
## can be obtained using 'which = "most"' and 'recursive = "strong"'.
## To illustrate on the first packages with non-missing Suggests:
packages <- pdb[head(which(!is.na(pdb[, "Suggests"]))), "Package"]
package_dependencies(packages, db = pdb,
                    which = "most", recursive = "strong")
```

---

```
package_native_routine_registration_skeleton
```

*Write Skeleton for Adding Native Routine Registration to a Package*

---

## Description

Write a skeleton for adding native routine registration to a package.

## Usage

```
package_native_routine_registration_skeleton(dir, con = stdout(),
  align = TRUE, character_only = TRUE, include_declarations = TRUE)
```

## Arguments

|                                   |  |
|-----------------------------------|--|
| <code>dir</code>                  | Top-level directory of a package.  |
| <code>con</code>                  | Connection on which to write the skeleton: can be specified as a file path.  |
| <code>align</code>                | Logical: should the registration tables be lined up in three columns each?   |
| <code>character_only</code>       | Logical: should only <code>.NAME</code> arguments specified by character strings (and not as names of R objects nor expressions) be extracted? |
| <code>include_declarations</code> | Logical: should the output include declarations (also known as ‘prototypes’) for the registered routines?                                      |

## Details

Registration is described in section ‘Registering native routines’ of ‘Writing R Extensions’. This function produces a skeleton of the C code which needs to be added to enable registration, conventionally as file ‘src/init.c’ or appended to the sole C file of the package.

This function examines the code in the ‘R’ directory of the package for calls to `.C`, `.Fortran`, `.Call` and `.External` and creates registration information for those it can make sense of. If the number of arguments used cannot be determined it will be recorded as `-1`: such values should be corrected.

Optionally the skeleton will include declarations for the registered routines: they should be checked against the C/Fortran source code, not least as the number of arguments is taken from the R code. For `.Call` and `.External` calls they will often suffice, but for `.C` and `.Fortran` calls the ‘`void*`’ arguments would ideally be replaced by the actual types. Otherwise declarations need to be included (they may exist earlier in that file if appending to a file, or in a header file which can be included in ‘init.c’).

The default value of `character_only` is appropriate when working on a package without any existing registration: `character_only = FALSE` can be used to suggest updates for a package which has been extended since registration. For the default value, if `.NAME` values are found which are not character strings (e.g. names or expressions) this is noted via a comment in the output.

Packages which used the earlier form of creating R objects for native symbols *via* additional arguments in a `useDynLib` directive will probably most easily be updated to use registration with `character_only = FALSE`.

If an entry point is used with different numbers of arguments in the package’s R code, an entry in the table (and optionally, a declaration) is made for each number, and a comment placed in the output. This needs to be resolved: only `.External` calls can have a variable number of arguments, which should be declared as `-1`.

A surprising number of CRAN packages had calls in R code to native routines not included in the package, which will lead to a ‘loading failed’ error during package installation when the registration C code is added.

Calls which do not name a routine such as `.Call(...)` will be silently ignored.

## Value

None: the output is written to the connection `con`.

## Extracting C/C++ prototypes

There are several tools available to extract function declarations from C or C++ code.

For C code one can use `cproto` (<https://invisible-island.net/cproto/cproto.html>; Windows executables are available), for example

```
cproto -I/path/to/R/include -e *.c
```

`ctags` (commonly distributed with the OS) covers C and C++, using something like

```
ctags -x *.c
```

to list all function usages. (The ‘Exuberant’ version allows a lot more control.)

## Extracting Fortran prototypes

gfortran 9.2 and later can extract C prototypes for Fortran subroutines with a special flag:

```
gfortran -c -fc-prototypes-external file.f
```

although ironically not for functions declared `bind(C)`.

## Note

This only examines the 'R' directory: it will not find e.g. `.Call` calls used directly in examples, tests *etc.*

Static code analysis is used to find the `.C` etc calls: it *will* find those in parts of the R code 'commented out' by inclusion in `if (FALSE) { ... }`. On the other hand, it will fail to find the entry points in constructs like

```
.Call(if(int) "rle_i" else "rle_d", i, force)
```

and does not know the value of variables in calls like

```
.Call (cfunction, ...)
.Call(..., PACKAGE="sparseLTSEigen")
```

(but if `character_only` is false, will extract the first as `"cfunction"`). Calls which have not been fully resolved will be noted *via* comments in the output file.

Call to entry points in other packages will be ignored if they have an explicit (character string) `PACKAGE` argument.

```

---

parseLatex

---

*Experimental Functions to Work with LaTeX Code*

---

## Description

The `parseLatex` function parses LaTeX source, producing a structured object; `deparseLatex` reverses the process. The `latexToUtf8` function takes a LaTeX object, and processes a number of different macros to convert them into the corresponding UTF-8 characters.

## Usage

```

parseLatex(text, filename = deparse1(substitute(text)),
           verbose = FALSE,
           verbatim = c("verbatim", "verbatim*",
                        "Sinput", "Soutput"),
           verb = "\\Sexpr")
deparseLatex(x, dropBraces = FALSE)
latexToUtf8(x)

```

## Arguments

|                         |  |
|-------------------------|--|
| <code>text</code>       | A character vector containing LaTeX source code.   |
| <code>filename</code>   | A filename to use in syntax error messages.  |
| <code>verbose</code>    | If TRUE, print debug error messages.   |
| <code>verbatim</code>   | A character vector containing the names of LaTeX environments holding verbatim text.     |
| <code>verb</code>       | A character vector containing LaTeX macros that should be assumed to hold verbatim text. |
| <code>x</code>          | A "LaTeX" object.  |
| <code>dropBraces</code> | Drop unnecessary braces when displaying a "LaTeX" object.                                |

## Details

The parser does not recognize all legal LaTeX code, only relatively simple examples. It does not associate arguments with macros, that needs to be done after parsing, with knowledge of the definitions of each macro. The main intention for this function is to process simple LaTeX code used in bibliographic references, not fully general LaTeX documents.

Verbose text is allowed in three forms: the `\verb` macro (with single character delimiters), environments whose names are listed in the `verbatim` argument, and other macros (with brace delimiters) whose names are listed in the `verb` argument.

### Value

The `parseLatex()` function returns a recursive object of class "LaTeX". Each of the entries in this object will have a "latex\_tag" attribute identifying its syntactic role.

The `deparseLatex()` function returns a single element character vector, possibly containing embedded newlines.

The `latexToUtf8()` function returns a modified version of the "LaTeX" object that was passed to it.

### Author(s)

Duncan Murdoch

### Examples

```
latex <- parseLatex("fran\\c{c}ais")
deparseLatex(latexToUtf8(latex))
```

---

parse\_Rd

*Parse an Rd File*

---

### Description

This function reads an R documentation (Rd) file and parses it, for processing by other functions.

### Usage

```
parse_Rd(file, srcfile = NULL, encoding = "unknown",
         verbose = FALSE, fragment = FALSE, warningCalls = TRUE,
         macros = file.path(R.home("share"), "Rd", "macros", "system.Rd"),
         permissive = FALSE)
## S3 method for class 'Rd'
print(x, deparse = FALSE, ...)
## S3 method for class 'Rd'
as.character(x, deparse = FALSE, ...)
```

### Arguments

|                           |  |
|---------------------------|--|
| <code>file</code>         | A filename or text-mode connection. At present filenames work best.                                      |
| <code>srcfile</code>      | NULL, or a "srcfile" object. See the 'Details' section.  |
| <code>encoding</code>     | Encoding to be assumed for input strings.  |
| <code>verbose</code>      | Logical indicating whether detailed parsing information should be printed.                               |
| <code>fragment</code>     | Logical indicating whether file represents a complete Rd file, or a fragment.                            |
| <code>warningCalls</code> | Logical: should parser warnings include the call?  |
| <code>macros</code>       | Filename or environment from which to load additional macros, or a logical value. See the Details below. |

|            |   |
|------------|---|
| permissive | Logical indicating that unrecognized macros should be treated as text with no warning.                              |
| x          | An object of class Rd.  |
| deparse    | If TRUE, attempt to reinstate the escape characters so that the resulting characters will parse to the same object. |
| ...        | Further arguments to be passed to or from other methods.  |

## Details

This function parses ‘Rd’ files according to the specification given in <https://developer.r-project.org/parseRd.pdf>.

It generates a warning for each parse error and attempts to continue parsing. In order to continue, it is generally necessary to drop some parts of the file, so such warnings should not be ignored.

Files without a marked encoding are by default assumed to be in the native encoding. An alternate default can be set using the `encoding` argument. All text in files is translated to the UTF-8 encoding in the parsed object.

As from R version 3.2.0, User-defined macros may be given in a separate file using ‘\newcommand’ or ‘\renewcommand’. An environment may also be given: it would be produced by `loadRdMacros`, `loadPkgRdMacros`, or by a previous call to `parse_Rd`. If a logical value is given, only the default built-in macros will be used; FALSE indicates that no "macros" attribute will be returned with the result.

The `permissive` argument allows text to be parsed that is not completely in Rd format. Typically it would be LaTeX code, used in an Rd fragment, e.g. in a `bibentry`. With `permissive = TRUE`, this will be passed through as plain text. Since `parse_Rd` doesn’t know how many arguments belong in LaTeX macros, it will guess based on the presence of braces after the macro; this is not infallible.

## Value

`parse_Rd` returns an object of class "Rd". The internal format of this object is subject to change. The `as.character()` and `print()` methods defined for the class return character vectors and print them, respectively.

Unless `macros = FALSE`, the object will have an attribute named "macros", which is an environment containing the macros defined in `file`, in a format that can be used for further `parse_Rd` calls in the same session. It is not guaranteed to work if saved to a file and reloaded in a different session.

## Author(s)

Duncan Murdoch

## References

<https://developer.r-project.org/parseRd.pdf>

## See Also

[Rd2HTML](#) for the converters that use the output of `parse_Rd()`.

## Description

Generate a single-page HTML reference manual from the Rd sources contained in an installed or source R package.

## Usage

```
pkg2HTML(package, dir = NULL, lib.loc = NULL,
          outputEncoding = "UTF-8",
          stylesheet = file.path(R.home("doc"), "html", "R-nav.css"),
          hooks = list(pkg_href = function(pkg) sprintf("%s.html", pkg)),
          texmath = getOption("help.htmlmath"),
          prism = TRUE,
          out = NULL,
          toc_entry = c("title", "name"),
          ...,
          Rhtml = FALSE,
          mathjax_config = file.path(R.home("doc"), "html", "mathjax-config.js"),
          include_description = TRUE)
```

## Arguments

|                |   |
|----------------|---|
| package        | a character string, typically giving the name of an installed package. Can also be a file path or URL pointing to a source tarball (this feature is experimental).  |
| dir            | character string giving the path to a directory containing an installed or source package.  |
| lib.loc        | a character vector describing the location of R library trees to search through, or NULL. Passed on to <a href="#">find.package</a> and <a href="#">Rd_db</a> .   |
| outputEncoding | character string; see <a href="#">Rd2HTML</a> .   |
| stylesheet     | character string giving URL containing CSS style information.   |
| hooks          | A list of functions controlling details of output. Currently the only component used is <code>pkg_href</code> , which is used to determine the output HTML file path given a package name as input.   |
| texmath        | character string controlling math rendering library to be used, either "katex" or "mathjax". The default is to use "katex", unless the package appears to use the <a href="#">mathjaxr</a> package in at least one of its documentation files. The support for MathJax is experimental and may not work well. |
| prism          | logical flag controlling code highlighting, as described in <a href="#">Rd2HTML</a> .   |
| out            | a filename or connection object to which to write the output. By default (NULL), the filename is inferred from <code>hooks\$pkg_href</code> , which defaults to <code>'pkg.html'</code> .   |
| toc_entry      | Determines whether the entry for a help page in the table of contents is the name of the help page or its title.  |

... additional arguments, passed on to [Rd2HTML](#). The `stages` argument, if specified, is passed on to [Rd\\_db](#).

`Rhtml` logical: whether the output is intended to be a Rhtml file that can be processed using **knitr**. If TRUE, the examples section is wrapped inside a `rcode` block.

`mathjax_config` character string giving path of file containing configuration instructions for mathjax. Relevant only if `texmath = "mathjax"`.

`include_description` logical flag indicating whether the output should begin with the contents of the DESCRIPTION file.

### Details

The `pkg2HTML` function is intended to produce a single-page HTML reference manual for a given package, with links to other packages. The URLs of links to external packages are controlled by the provided hooks.

The handling of `\Sexpr`-s are necessarily incomplete, but can be controlled to some extent by specifying the `stages` argument. Best results are likely for installed packages.

### Value

The name of the output file (invisibly).

### Author(s)

Deepayan Sarkar

### See Also

### Examples

```
pkg2HTML("tools", out = tempfile(fileext = ".html")) |> browseURL()
```

---

pskill

*Kill a Process*

---

### Description

`pskill` sends a signal to a process, usually to terminate it.

### Usage

```
pskill(pid, signal = SIGTERM)
```

```
SIGHUP
SIGINT
SIGQUIT
SIGKILL
```

SIGTERM  
SIGSTOP  
SIGTSTP  
SIGCHLD  
SIGUSR1  
SIGUSR2

## Arguments

|        |   |
|--------|---|
| pid    | positive integers: one or more process IDs as returned by <code>Sys.getpid</code> . |
| signal | integer, most often one of the symbolic constants.                                  |

## Details

Signals are a C99 concept, but only a small number are required to be supported (of those listed, only `SIGINT` and `SIGTERM`). They are much more widely used on POSIX operating systems (which should define all of those listed here), which also support a `kill` system call to send a signal to a process, most often to terminate it. Function `pskill` provides a wrapper: it silently ignores invalid values of its arguments, including zero or negative pids.

In normal use on a Unix-alike, `Ctrl-C` sends `SIGINT`, `Ctrl-\` sends `SIGQUIT` and `Ctrl-Z` sends `SIGTSTP`: that and `SIGSTOP` suspend a process which can be resumed by `SIGCONT`.

The signals are small integers, but the actual numeric values are not standardized (and most do differ between OSes). The `SIG*` objects contain the appropriate integer values for the current platform (or `NA_INTEGER_` if the signal is not defined).

Only `SIGINT` and `SIGTERM` will be defined on Windows, and `pskill` will always use the Windows system call `TerminateProcess`.

## Value

A logical vector of the same length as `pid`, `TRUE` (for success) or `FALSE`, invisibly.

## See Also

Package **parallel** has several means to launch child processes which record the process IDs.

`psnice`

## Examples

```
## Not run:  
pskill(c(237, 245), SIGKILL)  
  
## End(Not run)
```

psnice

*Get or Set the Priority (Niceness) of a Process***Description**

Get or set the ‘niceness’ of the current process, or one or more other processes.

**Usage**

```
psnice(pid = Sys.getpid(), value = NA_integer_)
```

**Arguments**

|       |   |
|-------|---|
| pid   | positive integers: the process IDs of one or more processes: defaults to the R session process. |
| value | The niceness to be set, or NA for an enquiry.   |

**Details**

POSIX operating systems have a concept of process priorities, usually from 0 to 39 (or 40) with 20 being a normal priority and (somewhat confusingly) larger numeric values denoting lower priority. To add to the confusion, there is a ‘niceness’ value, the amount by which the priority numerically exceeds 20 (which can be negative). Processes with high niceness will receive less CPU time than those with normal priority. On some OSes, processes with niceness +19 are only run when the system would otherwise be idle.

On many OSes utilities such as `top` report the priority and not the niceness. Niceness is used by the utility `/usr/bin/renice`: `/usr/bin/nice` (and `/usr/bin/renice -n`) specifies an *increment* in niceness.

Only privileged users (usually super-users) can lower the niceness.

Windows has a slightly different concept of ‘priority classes’. We have mapped the idle priority to niceness 19, ‘below normal’ to 15, normal to 0, ‘above normal’ to -5 and ‘realtime’ to -10. Unlike Unix-alikes, a non-privileged user can increase the priority class on Windows (but using ‘realtime’ is inadvisable).

**Value**

An integer vector of *previous* niceness values, NA if unknown for any reason.

**See Also**

Various functions in package **parallel** create child processes whose priority may need to be changed. [pskill](#).

**Description**

Functions for performing various quality control (QC) checks on R code and documentation, notably on R packages.

**Usage**

```
checkDocFiles (package, dir, lib.loc = NULL, chkInternal = NULL)
checkDocStyle (package, dir, lib.loc = NULL)
checkReplaceFuns (package, dir, lib.loc = NULL)
checkS3methods (package, dir, lib.loc = NULL)
checkRdContents (package, dir, lib.loc = NULL, chkInternal = NULL)

langElts
nonS3methods (package)
```

**Arguments**

|                          |   |
|--------------------------|---|
| <code>package</code>     | a character string naming an installed package.   |
| <code>dir</code>         | a character string specifying the path to a package's root source (or <i>installed</i> in some cases) directory. This should contain the subdirectories 'R' (for R code) and 'man' with R documentation sources (in Rd format). Only used if <code>package</code> is not given. |
| <code>lib.loc</code>     | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. The specified library trees are used to search for <code>package</code> .                                     |
| <code>chkInternal</code> | logical indicating if Rd files marked with keyword <code>internal</code> should be checked as well. If <code>NULL</code> (default), these are checked "specially", ignoring missing documentation of arguments.   |

**Details**

`checkDocFiles` checks, for all Rd files in a package, whether all arguments shown in the usage sections of the Rd file are documented in its arguments section. It also reports duplicated entries in the arguments section, and 'over-documented' arguments which are given in the arguments section but not in the usage.

`checkDocStyle` investigates how (S3) methods are shown in the usages of the Rd files in a package. It reports the methods shown by their full name rather than using the Rd `\method` markup for indicating S3 methods. Earlier versions of R also reported about methods shown along with their generic, which typically caused problems for the documentation of the primary argument in the generic and its methods. With `\method` now being expanded in a way that class information is preserved, joint documentation is no longer necessarily a problem. (The corresponding information is still contained in the object returned by `checkDocStyle`.)

`checkReplaceFuns` checks whether replacement functions or S3/S4 replacement methods in the package R code have their final argument named `value`.

`checkS3methods` checks whether all S3 methods defined in the package R code have all arguments of the corresponding generic, with positional arguments of the generics in the same positions

for the method. As an exception, the first argument of a formula method *may* be called `formula` even if this is not the name used by the generic. The rules when `...` is involved are subtle: see the source code. Functions recognized as S3 generics are those with a call to `UseMethod` in their body, internal S3 generics (see [InternalMethods](#)), and S3 group generics (see [Math](#)). Possible dispatch under a different name is not taken into account. The generics are sought first in the given package, then (if given an installed package) in the package imports, and finally the namespace environment for the **base** package.

`checkRdContents()` checks Rd content, e.g., whether arguments of functions in the usage section have non empty descriptions.

`nonS3methods(package)` returns a [character](#) vector with the names of the functions in package which ‘look’ like S3 methods, but are not. Using `package = NULL` returns all known examples.

`langElts` is a character vector of names of “language elements” of R. These are implemented as “very primitive” functions (no argument list; `print()` ing as `.Primitive("name")`).

If using an installed package, the checks needing access to all R objects of the package will load the package (unless it is the **base** package), after possibly detaching an already loaded version of the package.

## Value

The functions return objects of class the same as the respective function names containing the information about problems detected. There are `print` methods for nicely displaying the information contained in such objects.

---

Rcmd

R CMD *Interface*

---

## Description

Invoke R CMD tools from within R.

## Usage

```
Rcmd(args, ...)
```

## Arguments

|                   |   |
|-------------------|---|
| <code>args</code> | a character vector of arguments to R CMD.           |
| <code>...</code>  | arguments to be passed to <a href="#">system2</a> . |

## Details

Provides a portable convenience interface to the R CMD mechanism by invoking the corresponding system commands (using the version of R currently used) via [system2](#).

## Value

See section “Value” in [system2](#).

**Description**

These functions take the output of `parse_Rd()`, an Rd object, and produce a help page from it. As they are mainly intended for internal use, their interfaces are subject to change.

**Usage**

```
Rd2HTML(Rd, out = "", package = "", defines = .Platform$OS.type,
        Links = NULL, Links2 = NULL,
        stages = "render", outputEncoding = "UTF-8",
        dynamic = FALSE, no_links = FALSE, fragment = FALSE,
        stylesheet = if (dynamic) "/doc/html/R.css" else "R.css",
        texmath = getOption("help.htmlmath"),
        concordance = FALSE,
        standalone = TRUE,
        hooks = list(),
        toc = isTRUE(getOption("help.htmltoc")),
        Rhtml = FALSE,
        ...)
```

```
Rd2txt(Rd, out = "", package = "", defines = .Platform$OS.type,
        stages = "render", outputEncoding = "",
        fragment = FALSE, options, ...)
```

```
Rd2latex(Rd, out = "", defines = .Platform$OS.type,
          stages = "render", outputEncoding = "UTF-8",
          fragment = FALSE, ..., writeEncoding = TRUE,
          concordance = FALSE)
```

```
Rd2ex(Rd, out = "", defines = .Platform$OS.type,
       stages = "render", outputEncoding = "UTF-8",
       commentDontrun = TRUE, commentDonttest = FALSE, ...)
```

**Arguments**

|                             |  |
|-----------------------------|--|
| <code>Rd</code>             | a filename or Rd object to use as input.   |
| <code>out</code>            | a filename or connection object to which to write the output. The default <code>out = ""</code> is equivalent to <code>out = stdout()</code> . |
| <code>package</code>        | the package to list in the output.   |
| <code>defines</code>        | string(s) to use in <code>#ifdef</code> tests.   |
| <code>stages</code>         | at which stage ("build", "install", or "render") should <code>\Sexpr</code> macros be executed? See the notes below.                           |
| <code>outputEncoding</code> | see the ‘Encodings’ section below.   |
| <code>dynamic</code>        | logical: set links for render-time resolution by dynamic help system.  |
| <code>no_links</code>       | logical: suppress hyperlinks to other help topics. Used by R CMD <code>Rdconv</code> .   |

|                              |   |
|------------------------------|---|
| <code>fragment</code>        | logical: should fragments of Rd files be accepted? See the notes below.   |
| <code>stylesheet</code>      | character: a URL for a stylesheet to be used in the header of the HTML output page.   |
| <code>texmath</code>         | character: controls how mathematics in <code>\eqn</code> and <code>\deqn</code> commands are typeset in HTML output. Useful values are <code>"katex"</code> (default) and <code>"mathjax"</code> to use <b>KaTeX</b> or <b>MathJax</b> respectively, otherwise basic substitutions are used. May be ignored under certain circumstances, e.g., if the help page already uses macros from the <code>mathjaxr</code> package. |
| <code>concordance</code>     | Whether concordance data should be embedded in the output file and attached to the return value.  |
| <code>standalone</code>      | logical: whether the output is intended to be a standalone HTML file. If <code>FALSE</code> , the header and footer are omitted, so that the output can be combined with other fragments.   |
| <code>hooks</code>           | A list of functions controlling details of output. Currently the only component used is <code>pkg_href</code> , which is used by <code>pkg2HTML</code> to determine the output HTML file path given a package name as input.  |
| <code>toc</code>             | logical: whether the HTML output should include a table of contents. Ignored unless <code>standalone = TRUE</code> .  |
| <code>Rhtml</code>           | logical: whether the output is intended to be a Rhtml file that can be processed using <b>knitr</b> . If <code>TRUE</code> , the examples section is wrapped inside a <code>rcode</code> block.   |
| <code>Links, Links2</code>   | <code>NULL</code> or a named (by topics) character vector of links, as returned by <code>findHTMLlinks</code> .   |
| <code>options</code>         | An optional named list of options to pass to <code>Rd2txt_options</code> .  |
| <code>...</code>             | additional parameters to pass to <code>parse_Rd</code> when <code>Rd</code> is a filename.  |
| <code>writeEncoding</code>   | should <code>\inputencoding</code> lines be written in the file for non-ASCII encodings?  |
| <code>commentDontrun</code>  | should <code>\dontrun</code> sections be commented out?   |
| <code>commentDonttest</code> | should <code>\donttest</code> sections be commented out?  |

## Details

These functions convert help documents: `Rd2HTML` produces HTML, `Rd2txt` produces plain text, `Rd2latex` produces LaTeX. `Rd2ex` extracts the examples in the format used by `example` and `R` utilities.

Each of the functions accepts a filename for an Rd file, and will use `parse_Rd` to parse it before applying the conversions or checks.

The difference between arguments `Link` and `Link2` is that links are looked in them in turn, so lazy-evaluation can be used to only do a second-level search for links if required.

Before R 3.6.0, the default for `Rd2latex` was `outputEncoding = "ASCII"`, including using the second option of `\enc` markup, because  $\text{\LaTeX}$  versions did not provide enough coverage of UTF-8 glyphs for a long time.

`Rd2txt` will format text paragraphs to a width determined by `width`, with appropriate margins. The default is to be close to the rendering in versions of R < 2.10.0.

`Rd2txt` will use directional quotes (see `sQuote`) if option `"useFancyQuotes"` is true (usually the default, see `sQuote`) and the current encoding is UTF-8.

Various aspects of formatting by `Rd2txt` are controlled by the `options` argument, documented with the `Rd2txt_options` function. Changes made using `options` are temporary, those made with `Rd2txt_options` are persistent.

When `fragment = TRUE`, the Rd file will be rendered with no processing of `\Sexpr` elements or conditional defines using `#ifdef` or `#ifndef`. Normally a fragment represents text within a section, but if the first element of the fragment is a section macro, the whole fragment will be rendered as a series of sections, without the usual sorting.

## Value

These functions are executed mainly for the side effect of writing the converted help page. Their value is the name of the output file (invisibly). For `Rd2latex`, the output name is given an attribute `"latexEncoding"` giving the encoding of the file in a form suitable for use with the LaTeX `'inputenc'` package. For `Rd2HTML` with `standalone = FALSE`, an attribute `"info"` gives supplementary information such as the contents of the `name` and `title` fields. This is currently experimental, and the details are subject to change.

For `Rd2HTML` and `Rd2latex` with `concordance = TRUE`, a `"concordance"` attribute is added, containing an `Rconcordance` object.

## Encodings

Rd files are normally intended to be rendered on a wide variety of systems, so care must be taken in the encoding of non-ASCII characters. In general, any such encoding should be declared using the `'encoding'` section for there to be any hope of correct rendering.

For output, the `outputEncoding` argument will be used: `outputEncoding = ""` will choose the native encoding for the current system.

If the text cannot be converted to the `outputEncoding`, byte substitution will be used (see [iconv](#)): `Rd2latex` and `Rd2ex` give a warning.

## Note

The `\Sexpr` macro includes R code that will be executed at one of three times: *build* time (when a package's source code is built into a tarball), *install* time (when the package is installed or built into a binary package), and *render* time (when the man page is converted to a readable format).

For example, this man page was:

1. built on 2024-12-25 at 10:28:46,
2. installed on 2024-12-25 at 10:28:46, and
3. rendered on 2024-12-25 at 10:37:38.

## Examples

```
## Simulate rendering of this (installed) page in HTML and text format
Rd <- Rd_db("tools")["Rd2HTML.Rd"]

outfile <- tempfile(fileext = ".html")
Rd2HTML(Rd, outfile, package = "tools") |> browseURL()

outfile <- tempfile(fileext = ".txt")
Rd2txt(Rd, outfile, package = "tools") |> file.show()
```

---

Rd2txt\_options

Set Formatting Options for Text Help

---

## Description

This function sets various options for displaying text help.

## Usage

```
Rd2txt_options(...)
```

## Arguments

... A list containing named options, or options passed as individual named arguments. See below for currently defined ones.

## Details

This function persistently sets various formatting options for the `Rd2txt` function which is used in displaying text format help. Currently defined options are:

**width** (default 80): The width of the output page.

**minIndent** (default 10): The minimum indent to use in a list.

**extraIndent** (default 4): The extra indent to use in each level of nested lists.

**sectionIndent** (default 5): The indent level for a section.

**sectionExtra** (default 2): The extra indentation for each nested section level.

**itemBullet** (default " \* ", with the asterisk replaced by a Unicode bullet in UTF-8 and most Windows locales): The symbol to use as a bullet in itemized lists.

**enumFormat** : A function to format item numbers in enumerated lists.

**showURLs** (default FALSE): Whether to show URLs when expanding `\href` tags.

**code\_quote** (default TRUE): Whether to render `\code` and similar with single quotes.

**underline\_titles** (default TRUE): Whether to render section titles with underlines (via backspacing).

## Value

If called with no arguments, returns all option settings in a list. Otherwise, it changes the named settings and invisibly returns their previous values.

**Author(s)**

Duncan Murdoch

**See Also**[Rd2txt](#)**Examples**

```

saveOpts <- Rd2txt_options()
saveOpts
Rd2txt_options(minIndent = 4)
Rd2txt_options()[["minIndent"]]
Rd2txt_options(saveOpts)
stopifnot(identical(Rd2txt_options(), saveOpts))

```

Rdiff

*Difference R Output Files***Description**

Given two R output files, compute differences ignoring headers, footers and some other differences.

**Usage**

```

Rdiff(from, to, useDiff = FALSE, forEx = FALSE,
      nullPointers = TRUE, Log = FALSE)

```

**Arguments**

|              |  |
|--------------|--|
| from, to     | filepaths to be compared   |
| useDiff      | should diff be used to compare results? Overridden to false if the command is not available.                                   |
| forEx        | logical: extra pruning for ‘-Ex.Rout’ files to exclude headers and footers of examples, code and results for “--timings”, etc. |
| nullPointers | logical: should the displayed addresses of pointers be set to 0x00000000 before comparison?                                    |
| Log          | logical: should the returned value include a log of differences found?   |

**Details**

The R startup banner and any timing information from R CMD BATCH are removed from both files, together with lines about loading packages. UTF-8 fancy quotes (see [sQuote](#)) and on Windows, Windows’ so-called ‘smart quotes’, are mapped to a simple quote. Addresses of environments, compiled bytecode and other exotic types expressed as hex addresses (e.g., ‘<environment: 0x12345678>’) are mapped to 0x00000000. The files are then compared line-by-line. If there are the same number of lines and useDiff is false, a simple diff -b -like display of differences is printed (which ignores trailing spaces and differences in numbers of consecutive spaces), otherwise diff -bw is called on the edited files. (This tries to ignore all differences in whitespace: note that flag ‘-w’ is not required by POSIX but is supported by GNU, Solaris and FreeBSD versions – macOS uses an old GNU version.)

There is limited support for comparing PDF files produced by `pdf(compress = FALSE)`, mainly for use in `make check` – this requires a `diff` command and `useDiff = TRUE`.

Mainly for use in examples and tests, text from marker ‘> ## IGNORE\_RDIFF\_BEGIN’ up to (but not including) ‘> ## IGNORE\_RDIFF\_END’ is ignored.

### Value

If `Log` is true, a list with components `status` (see below) and `out`, a character vector of descriptions of differences, possibly of zero length.

Otherwise, a status indicator (invisibly), `0L` if and only if no differences were found.

### See Also

The shell script run as `R CMD Rdiff`, which uses `useDiff = TRUE`.

---

Rdindex

*Generate Index from Rd Files*

---

### Description

Print a 2-column index table with names and titles from given R documentation files to a given output file or connection. The titles are nicely formatted between two column positions (typically 25 and 72, respectively).

### Usage

```
Rdindex(RdFiles, outFile = "", type = NULL,
        width = 0.9 * getOption("width"), indent = NULL)
```

### Arguments

|                      |  |
|----------------------|--|
| <code>RdFiles</code> | a character vector specifying the Rd files to be used for creating the index, either by giving the paths to the files, or the path to a single directory with the sources of a package.  |
| <code>outFile</code> | a connection, or a character string naming the output file to print to. "" (the default) indicates output to the console.  |
| <code>type</code>    | a character string giving the documentation type of the Rd files to be included in the index, or <code>NULL</code> (the default). The type of an Rd file is typically specified via the <code>\docType</code> tag; if <code>type</code> is "data", Rd files whose <i>only</i> keyword is <code>datasets</code> are included as well. |
| <code>width</code>   | a positive integer giving the target column for wrapping lines in the output.  |
| <code>indent</code>  | a positive integer specifying the indentation of the second column. Must not be greater than <code>width/2</code> , and defaults to <code>width/3</code> .   |

### Details

If a name is not a valid alias, the first alias (or the empty string if there is none) is used instead.

---

|              |                           |
|--------------|---------------------------|
| RdTextFilter | Select Text in an Rd File |
|--------------|---------------------------|

---

## Description

This function blanks out all non-text in an Rd file, for spell checking or other uses.

## Usage

```
RdTextFilter(ifile, encoding = "unknown", keepSpacing = TRUE,  
             drop = character(), keep = character(),  
             macros = file.path(R.home("share"), "Rd", "macros", "system.Rd"))
```

## Arguments

|                          |  |
|--------------------------|--|
| <code>ifile</code>       | An input file specified as a filename or connection, or an "Rd" object from <a href="#">parse_Rd</a> . |
| <code>encoding</code>    | An encoding name to pass to <a href="#">parse_Rd</a> .   |
| <code>keepSpacing</code> | Whether to try to leave the text in the same lines and columns as in the original file.                |
| <code>drop</code>        | Additional sections of the Rd to drop.   |
| <code>keep</code>        | Sections of the Rd file to keep.   |
| <code>macros</code>      | Macro definitions to assume when parsing. See <a href="#">parse_Rd</a> .                               |

## Details

This function parses the Rd file, then walks through it, element by element. Items with tag "TEXT" are kept in the same position as they appeared in the original file, while other parts of the file are replaced with blanks, so a spell checker such as [aspell](#) can check only the text and report the position in the original file. (If `keepSpacing` is FALSE, blank filling will not occur, and text will not be output in its original location.)

By default, the tags `\S3method`, `\S4method`, `\command`, `\docType`, `\email`, `\encoding`, `\file`, `\keyword`, `\link`, `\linkS4class`, `\method`, `\pkg`, and `\var` are skipped. Additional tags can be skipped by listing them in the `drop` argument; listing tags in the `keep` argument will stop them from being skipped. It is also possible to keep any of the `c("RCODE", "COMMENT", "VERB")` tags, which correspond to R-like code, comments, and verbatim text respectively, or to drop "TEXT".

## Value

A character vector which if written to a file, one element per line, would duplicate the text elements of the original Rd file.

## Note

The filter attempts to merge text elements into single words when markup in the Rd file is used to highlight just the start of a word.

## Author(s)

Duncan Murdoch

**See Also**

[aspell](#), for which this is an acceptable filter.

---

Rdutils

*Rd Utilities*

---

**Description**

Utilities for computing on the information in Rd objects.

**Usage**

```
Rd_db(package, dir, lib.loc = NULL, stages = "build")
```

**Arguments**

|                      |   |
|----------------------|---|
| <code>package</code> | a character string naming an installed package.   |
| <code>dir</code>     | a character string specifying the path to a package's root source directory. This should contain the subdirectory 'man' with R documentation sources (in Rd format). Only used if <code>package</code> is not given.                        |
| <code>lib.loc</code> | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. The specified library trees are used to search for <code>package</code> . |
| <code>stages</code>  | if <code>dir</code> is specified and the database is being built from source, which stages of <code>\Sexpr</code> processing should be processed?   |

**Details**

`Rd_db` builds a simple database of all Rd objects in a package, as a list of the results of running [parse\\_Rd](#) on the Rd source files in the package and processing platform conditionals and some `\Sexpr` macros.

**See Also**

[parse\\_Rd](#)

**Examples**

```
## Build the Rd db for the (installed) base package.
db <- Rd_db("base")

## Keyword metadata per Rd object.
keywords <- lapply(db, tools:::Rd_get_metadata, "keyword")
## Tabulate the keyword entries.
kw_table <- sort(table(unlist(keywords)))
## The 5 most frequent ones:
rev(kw_table)[1 : 5]
## The "most informative" ones:
kw_table[kw_table == 1]

## Concept metadata per Rd file.
concepts <- lapply(db, tools:::Rd_get_metadata, "concept")
```

```
## How many files already have \concept metadata?  
sum(sapply(concepts, length) > 0)  
## How many concept entries altogether?  
length(unlist(concepts))
```

---

|              |                                 |
|--------------|---------------------------------|
| read.00Index | <i>Read 00Index-style Files</i> |
|--------------|---------------------------------|

---

## Description

Read item/description information from ‘00Index’-like files. Such files are description lists rendered in tabular form, and currently used for the ‘INDEX’ and ‘demo/00Index’ files of add-on packages.

## Usage

```
read.00Index(file)
```

## Arguments

|      |  |
|------|--|
| file | the name of a file to read data values from. If the specified file is "", then input is taken from the keyboard (in this case input can be terminated by a blank line). Alternatively, file can be a <a href="#">connection</a> , which will be opened if necessary, and if so closed at the end of the function call. |
|------|--|

## Value

A character matrix with 2 columns named "Item" and "Description" which hold the items and descriptions.

## See Also

[formatDL](#) for the inverse operation of creating a 00Index-style file from items and their descriptions.

---

|              |                                      |
|--------------|--------------------------------------|
| showNonASCII | <i>Pick Out Non-ASCII Characters</i> |
|--------------|--------------------------------------|

---

## Description

This function prints elements of a character vector which contain non-ASCII bytes, printing such bytes as a escape like ‘<fc>’.

## Usage

```
showNonASCII(x)  
  
showNonASCIIfile(file)
```

**Arguments**

|                   |                     |
|-------------------|---------------------|
| <code>x</code>    | a character vector. |
| <code>file</code> | path to a file.     |

**Details**

This was originally written to help detect non-portable text in files in packages.

It prints all elements of `x` which contain non-ASCII characters, preceded by the element number and with non-ASCII bytes highlighted *via* `iconv(sub = "byte")`.

However, this rendering depends on `iconv(to = "ASCII")` failing to convert, and macOS 14 no longer does so reliably so for example permille (‘\u2030’) is rendered as o/oo.

**Value**

The elements of `x` containing non-ASCII characters will be returned invisibly.

**Examples**

```
out <- c(
  "fran\xE7ais: test of showNonASCII():",
  "\\details{",
  "  This is a good line",
  "  This has an \xfcmlaut in it.",
  "  OK again.",
  "}")
f <- tempfile()
cat(out, file = f, sep = "\n")

showNonASCIIfile(f)
unlink(f)
```

---

startDynamicHelp     *Start the Dynamic HTML Help System*

---

**Description**

This function starts the internal help server, so that HTML help pages are rendered when requested.

**Usage**

```
startDynamicHelp(start = TRUE)
```

**Arguments**

|                    |  |
|--------------------|--|
| <code>start</code> | logical: whether to start or shut down the dynamic help system. If NA, the server is started if not already running. |
|--------------------|--|

## Details

This function starts the internal HTTP server, which runs on the loopback interface ('127.0.0.1'). If `options("help.ports")` is set to a vector of non-zero integer values, `startDynamicHelp` will try those ports in order; otherwise, it tries up to 10 random ports to find one not in use. It can be disabled by setting the environment variable `R_DISABLE_HTTPD` to a non-empty value or `options("help.ports")` to 0.

`startDynamicHelp` is called by functions that need to use the server, so would rarely be called directly by a user.

Note that `options(help_type = "html")` must be set to actually make use of HTML help, although it might be the default for an R installation.

If the server cannot be started or is disabled, `help.start` will be unavailable and requests for HTML help will give text help (with a warning).

The browser in use does need to be able to connect to the loopback interface: occasionally it is set to use a proxy for HTTP on all interfaces, which will not work – the solution is to add an exception for '127.0.0.1'.

## Value

The chosen port number is returned invisibly (which will be 0 if the server has been stopped).

## See Also

`help.start` and `help(help_type = "html")` will attempt to start the HTTP server if required

`Rd2HTML` is used to render the package help pages.

---

SweaveTeXFilter

*Strip R Code out of Sweave File*

---

## Description

This function blanks out code chunks and Noweb markup in an Sweave input file, for spell checking or other uses.

## Usage

```
SweaveTeXFilter(ifile, encoding = "unknown")
```

## Arguments

|                       |   |
|-----------------------|---|
| <code>ifile</code>    | Input file or connection.                         |
| <code>encoding</code> | Text encoding to pass to <code>readLines</code> . |

## Details

This function blanks out all Noweb markup and code chunks from an Sweave input file, leaving behind the LaTeX source, so that a LaTeX-aware spelling checker can check it and report errors in their original locations.

**Value**

A character vector which if written to a file, one element per line, would duplicate the text elements of the original Sweave input file.

**Author(s)**

Duncan Murdoch

**See Also**

[aspell](#), for which this is used with `filter = "Sweave"`.

---

testInstalledPackage

*Test Installed Packages*

---

**Description**

These functions allow an installed package to be tested, or all base and recommended packages.

**Usage**

```
testInstalledPackage(pkg, lib.loc = NULL, outDir = ".",
  types = c("examples", "tests", "vignettes"),
  srcdir = NULL, Ropts = "", ...)
```

```
testInstalledPackages(outDir = ".", errorsAreFatal = TRUE,
  scope = c("both", "base", "recommended"),
  types = c("examples", "tests", "vignettes"),
  srcdir = NULL, Ropts = "", ...)
```

```
testInstalledBasic(scope = c("basic", "devel", "both", "internet", "all"),
  outDir = file.path(R.home(), "tests"),
  testSrcdir = getTestSrcdir(outDir))
```

```
standard_package_names()
```

**Arguments**

|                             |  |
|-----------------------------|--|
| <code>pkg</code>            | name of an installed package.  |
| <code>lib.loc</code>        | library path(s) in which to look for the package. See <a href="#">library</a> .  |
| <code>outDir</code>         | the directory into which to write the output files: this should already exist. The default, <code>"."</code> is the current working directory. Often a subdirectory is preferable. |
| <code>types</code>          | type(s) of tests to be done.   |
| <code>srcdir</code>         | Optional directory to look for <code>.save</code> files.   |
| <code>Ropts</code>          | Additional options such as <code>'-dvalgrind'</code> to be passed to R CMD BATCH when running examples or tests.   |
| <code>errorsAreFatal</code> | logical: should testing terminate at the first error?  |

texi2dvi

*Compile LaTeX Files***Description**

Run `latex`/`pdflatex`, `makeindex` and `bibtex` until all cross-references are resolved to create a DVI or a PDF file.

**Usage**

```
texi2dvi(file, pdf = FALSE, clean = FALSE, quiet = TRUE,
         texi2dvi = getOption("texi2dvi"),
         texinputs = NULL, index = TRUE)

texi2pdf(file, clean = FALSE, quiet = TRUE,
         texi2dvi = getOption("texi2dvi"),
         texinputs = NULL, index = TRUE)
```

**Arguments**

|                        |   |
|------------------------|---|
| <code>file</code>      | character string. Name of the LaTeX source file.  |
| <code>pdf</code>       | logical. If <code>TRUE</code> , a PDF file is produced instead of the default DVI file ( <code>texi2dvi</code> command line option <code>--pdf</code> ).  |
| <code>clean</code>     | logical. If <code>TRUE</code> , all auxiliary files created during the conversion are removed.  |
| <code>quiet</code>     | logical. No output unless an error occurs.  |
| <code>texi2dvi</code>  | character string (or <code>NULL</code> ). Script or program used to compile a TeX file to DVI or PDF. The default (selected by <code>"</code> or <code>"texi2dvi"</code> or <code>NULL</code> ) is to look for a program or script named <code>texi2dvi</code> on the path and otherwise emulate the script with <code>system2</code> calls (which can be selected by the value <code>"emulation"</code> ). See also ‘Details’. |
| <code>texinputs</code> | <code>NULL</code> or a character vector of paths to add to the LaTeX and BibTeX input search paths.   |
| <code>index</code>     | logical: should indices be prepared?  |

**Details**

`texi2pdf` is a wrapper for the common case of `texi2dvi` (`pdf = TRUE`).

Despite the name, this is used in **R** to compile LaTeX files, specifically those generated from vignettes and by the `Rd2pdf` script (used for package reference manuals). It ensures that the `'R_HOME/share/texmf'` directory is in the `TEXINPUTS` path, so **R** style files such as `'Sweave.sty'` and `'Rd.sty'` will be found. The TeX search path used is first the existing `TEXINPUTS` setting (or the current directory if unset), then elements of argument `texinputs`, then `'R_HOME/share/texmf'` and finally the default path. Analogous changes are made to `BIBINPUTS` and `BSTINPUTS` settings.

The default option for `texi2dvi` is set from environment variable `R_TEXI2DVICMD`, and the default for that is set from environment variable `TEXI2DVI` or if that is unset, from a value chosen when **R** is configured.

A shell script `texi2dvi` is part of GNU's **texinfo**. Several issues have been seen with released versions, so if yours does not work correctly try `R_TEXI2DVICMD=emulation`.

Occasionally indices contain special characters which cause indexing to fail (particularly when using the ‘hyperref’ LaTeX package) even on valid input. The argument `index = FALSE` is provided to allow package manuals to be made when this happens: it uses emulation.

### Value

Invisible `NULL`. Used for the side effect of creating a DVI or PDF file in the current working directory (and maybe other files, especially if `clean = FALSE`).

### Note

There are various versions of the `texi2dvi` script on Unix-alikes and quite a number of bugs have been seen, some of which this R wrapper works around.

One that was present with `texi2dvi` version 4.8 (as supplied by macOS) is that it will not work correctly for paths which contain spaces, nor if the absolute path to a file would contain spaces.

The three possible approaches all have their quirks. For example the Unix-alike `texi2dvi` script removes ancillary files that already exist but the other two approaches do not (and may get confused by such files).

Where supported (`texi2dvi` 5.0 and later; `texify.exe` from MiKTeX), option ‘`--max-iterations=20`’ is used to avoid infinite retries.

The emulation mode supports `quiet = TRUE` from R 3.2.3 only. Currently `clean = TRUE` only cleans up in this mode if the conversion was successful—this gives users a chance to examine log files in the event of error.

All the approaches should respect the values of environment variables `LATEX`, `PDFLATEX`, `MAKEINDEX` and `BIBTEX` for the full paths to the corresponding commands.

toHTML

*Display an Object in HTML*

---

### Description

This generic function generates a complete HTML page from an object.

### Usage

```
toHTML(x, ...)
## S3 method for class 'packageIQR'
toHTML(x, ...)
## S3 method for class 'news_db'
toHTML(x, ...)
```

### Arguments

|                  |  |
|------------------|--|
| <code>x</code>   | An object to display.  |
| <code>...</code> | Optional parameters for methods; the "packageIQR" and "news_db" methods pass these to <a href="#">HTMLheader</a> . |

**Value**

A character vector to display the object `x`. The `"packageIQR"` method is designed to display lists in the R help system.

**See Also**

[HTMLheader](#)

**Examples**

```
cat(toHTML(demo(package = "base")), sep = "\n")
```

---

|                  |   |
|------------------|---|
| tools-deprecated | <i>Deprecated Objects in Package <b>tools</b></i> |
|------------------|---|

---

**Description**

(Currently none)

The functions or variables listed here are provided for compatibility with older versions of R only, and may be defunct as soon as of the next release.

**See Also**

[Deprecated, Defunct](#)

---

|      |  |
|------|--|
| toRd | <i>Generic Function to Convert Object to a Fragment of Rd Code</i> |
|------|--|

---

**Description**

Methods for this function render their associated classes as a fragment of Rd code, which can then be rendered into text, HTML, or LaTeX.

**Usage**

```
toRd(obj, ...)
## S3 method for class 'bibentry'
toRd(obj, style = NULL, ...)
```

**Arguments**

|                    |   |
|--------------------|---|
| <code>obj</code>   | The object to be rendered.  |
| <code>style</code> | The style to be used in converting a <a href="#">bibentry</a> object. |
| <code>...</code>   | Additional arguments used by methods.                                 |

**Details**

See [bibstyle](#) for a discussion of styles. The default `style = NULL` value gives the default style.

**Value**

Returns a character vector containing a fragment of Rd code that could be parsed and rendered. The default method converts `obj` to mode `character`, then escapes any Rd markup within it. The `bibentry` method converts an object of that class to markup appropriate for use in a bibliography.

---

|                          |                                     |
|--------------------------|-------------------------------------|
| <code>toTitleCase</code> | <i>Convert Titles to Title Case</i> |
|--------------------------|-------------------------------------|

---

**Description**

Convert a character vector to title case, especially package titles.

**Usage**

```
toTitleCase(text)
```

**Arguments**

`text`                    a character vector.

**Details**

This is intended for English text only.

No definition of ‘title case’ is universally accepted: all agree that ‘principal’ words are capitalized and common words like ‘for’ are not, but not which words fall into each category.

Generally words in all capitals are left alone: this implementation knows about conventional mixed-case words such as ‘LaTeX’ and ‘OpenBUGS’ and a few technical terms which are not usually capitalized such as ‘jar’ and ‘xls’. However, unknown technical terms will be capitalized unless they are single words enclosed in single quotes: names of packages and libraries should be quoted in titles.

**Value**

A character vector of the same length as `text`, without names.

---

|                    |                                  |
|--------------------|----------------------------------|
| <code>undoc</code> | <i>Find Undocumented Objects</i> |
|--------------------|----------------------------------|

---

**Description**

Finds the objects in a package which are undocumented, in the sense that they are visible to the user (or data objects or S4 classes provided by the package), but no documentation entry exists.

**Usage**

```
undoc(package, dir, lib.loc = NULL)
```

## Arguments

|                      |  |
|----------------------|--|
| <code>package</code> | a character string naming an installed package.  |
| <code>dir</code>     | a character string specifying the path to a package's root source directory. This must contain the subdirectory 'man' with R documentation sources (in Rd format), and at least one of the 'R' or 'data' subdirectories with R code or data objects, respectively. |
| <code>lib.loc</code> | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. The specified library trees are used to search for <code>package</code> .                        |

## Details

This function is useful for package maintainers mostly. In principle, *all* user-level R objects should be documented.

The **base** package is special as it contains the primitives and these do not have definitions available at code level. We provide equivalent closures in environments `.ArgsEnv` and `.GenericArgsEnv` in the **base** package that are used for various purposes: `undoc("base")` checks that all the primitives that are not language constructs are prototyped in those environments and no others are.

## Value

An object of class "undoc" which is a list of character vectors containing the names of the undocumented objects split according to documentation type.

There is a `print` method for nicely displaying the information contained in such objects.

## See Also

[codoc](#), [QC](#)

## Examples

```
undoc("tools") # Undocumented objects in 'tools'
```

---

|                              |                                       |
|------------------------------|---------------------------------------|
| <code>update_PACKAGES</code> | <i>Update Existing PACKAGES Files</i> |
|------------------------------|---------------------------------------|

---

## Description

Update an existing repository by reading the `PACKAGES` file, retaining entries which are still valid, removing entries which are no longer valid, and only processing built package tarballs which do not match existing entries.

`update_PACKAGES` can be much faster than [write\\_PACKAGES](#) for small-moderate changes to large repository indexes, particularly in non-strict mode (see [Details](#)).

## Usage

```
update_PACKAGES(dir = ".", fields = NULL, type = c("source",
  "mac.binary", "win.binary"), verbose.level = as.integer(dryrun),
  latestOnly = TRUE, addFiles = FALSE, rds_compress = "xz",
  strict = TRUE, dryrun = FALSE)
```

## Arguments

|                            |   |
|----------------------------|---|
| <code>dir</code>           | see <a href="#">write_PACKAGES</a> .  |
| <code>fields</code>        | see <a href="#">write_PACKAGES</a> .  |
| <code>type</code>          | see <a href="#">write_PACKAGES</a> .  |
| <code>verbose.level</code> | one of {0, 1, 2}, the level of informative messages displayed throughout the process. Defaults to 0 if <code>dryrun</code> is <code>FALSE</code> (the default) and 1 otherwise. See Details for more information. |
| <code>latestOnly</code>    | see <a href="#">write_PACKAGES</a> .  |
| <code>addFiles</code>      | see <a href="#">write_PACKAGES</a> .  |
| <code>rds_compress</code>  | see <a href="#">write_PACKAGES</a> .  |
| <code>strict</code>        | logical. Should “strict mode” be used when checking existing PACKAGES entries. See Details. Defaults to <code>TRUE</code> .   |
| <code>dryrun</code>        | logical. Should the updates to existing PACKAGES files be computed but NOT applied. Defaults to <code>FALSE</code> .  |

## Details

Throughout this section, *package tarball* is defined to mean any archive file in `dir` whose name can be interpreted as ‘*package\_version . ext*’ – with *ext* the appropriate extension for built packages of type `type` – (or that is pointed to by the `File` field of an existing PACKAGES entry). *Novel package tarballs* are those which do not match an existing PACKAGES file entry.

`update_PACKAGES` calls directly down to [write\\_PACKAGES](#) with a warning (and thus all package tarballs will be processed), if any of the following conditions hold:

- `type` is “win.binary” and `strict` is `TRUE` (no MD5 checksums are included in win.binary PACKAGES files)
- No PACKAGES file exists under `dir`
- A PACKAGES file exists under `dir` but is empty
- `fields` is not `NULL` and one or more specified fields are not present in the existing PACKAGES file

`update_PACKAGES` avoids (re)processing package tarballs in cases where a PACKAGES file entry already exists and appears to remain valid. The logic for detecting still-valid entries is as follows:

Any package tarball which was last modified more recently than the existing PACKAGES file is considered novel; existing PACKAGES entries appearing to correspond to such tarballs are *always* considered stale and replaced by newly generated ones. Similarly, all PACKAGES entries that do not correspond to any package tarball found in `dir` are considered invalid and are excluded from the resulting updated PACKAGES files.

When `strict` is `TRUE`, PACKAGES entries that match a package tarball (by package name and version) are confirmed via MD5 checksum; only those that pass are retained as valid. All novel package tarballs are fully processed by the standard machinery underlying [write\\_PACKAGES](#) and the resulting entries are added. Finally, if `latestOnly` is `TRUE`, package-version pruning is performed across the entries.

When `strict` is `FALSE`, package tarballs are assumed to encode correct metadata in their file-names. PACKAGES entries which appear to match a package tarball are retained as valid (No MD5 checksum testing occurs). If `latestOnly` is `TRUE`, package-version pruning is performed across the full set of retained entries and novel package tarballs *before* the processing of the novel tarballs,

at significant computational and time savings in some situations. After the optional pruning, any relevant novel package tarballs are processed via the standard machinery and added to the set of retained entries.

In both cases, after the above process concludes, entries are sorted alphabetically by the string concatenation of `Package` and `Version`. This should match the entry order `write_PACKAGES` outputs.

The fields within the entries are ordered as follows: canonical fields - i.e., those appearing as columns when `available.packages` is called on a CRAN mirror - appear first in their canonical order, followed by any non-canonical fields.

After entry and field reordering, the final database of `PACKAGES` entries is written to all three `PACKAGES` files, overwriting the existing versions.

When `verbose.level` is 0, no extra messages are displayed to the user. When it is 1, detailed information about what is happening is conveyed via messages, but underlying machinery from `write_PACKAGES` is invoked with `verbose = FALSE`. Behavior when `verbose.level` is 2 is identical to `verbose.level` 1 with the exception that underlying machinery from `write_PACKAGES` is invoked with `verbose = TRUE`, which will individually list every processed tarball.

### Note

While both strict and non-strict modes can offer speedups when updating small percentages of large repositories, non-strict mode is *much* faster and is recommended in situations where the assumption it makes about tarballs' filenames encoding accurate information is safe.

### Note

Users should expect significantly smaller speedups over `write_PACKAGES` in the `type == "win.binary"` case on at least some operating systems. This is due to `write_PACKAGES` being significantly faster in this context, rather than `update_PACKAGES` being slower.

type = "win.binary") # on Linux
update_PACKAGES("/pub/RWin/bin/windows/contrib/2.9",
type = "win.binary") # on Linux

## End(Not run)
```

---

|               |   |
|---------------|---|
| update_pkg_po | <i>Prepare Translations for a Package</i> |
|---------------|---|

---

## Description

Prepare the ‘po’ directory of a package and optionally compile and install the translations.

## Usage

```
update_pkg_po(pkgdir, pkg = NULL, version = NULL,
              pot_make = TRUE, mo_make = TRUE,
              verbose = getOption("verbose"),
              mergeOpts = "", copyright, bugs)
```

## Arguments

|                   |  |
|-------------------|--|
| pkgdir            | The path to the package directory.   |
| pkg               | The package name: if NULL it is read from the package’s ‘DESCRIPTION’ file.  |
| version           | The package version: if NULL it is read from the package’s ‘DESCRIPTION’ file.   |
| pot_make, mo_make | <a href="#">logicals</a> indicating if a new ‘*.pot’ file or new binary translations ‘*.mo’ should be (re)created.   |
| verbose           | <a href="#">logical</a> indicating if extra information about the updating process should be printed to the console.   |
| mergeOpts         | a string, by default empty, of space-separated options to msgmerge in addition to “--update”. Since R 4.2.0, “--no-wrap” is used when called from <code>file.path(R.home("po"), "Makefile")</code> . |
| copyright, bugs   | optional character strings for the ‘Copyright’ and ‘Report-Msgid-Bugs-To’ details in the template files.   |

## Details

This performs a series of steps to prepare or update messages in the package.

- If the package sources do not already have a ‘po’ directory, one is created.
- [xgettext2pot](#) is called to create/update a file ‘po/R-*pkgname*.pot’ containing the translatable messages in the package.
- All existing files in directory po with names ‘R-*lang*.po’ are updated from ‘R-*pkgname*.pot’, [checkPoFile](#) is called on the updated file, and if there are no problems the file is compiled and installed under ‘inst/po’.
- In a UTF-8 locale, a ‘translation’ ‘R-en@quot.pot’ is created with UTF-8 directional quotes, compiled and installed under ‘inst/po’.
- The remaining steps are done only if file ‘po/*pkgname*.pot’ already exists. The ‘src/\*.{c,cc,cpp,m,mm}’ files in the package are examined to create a file ‘po/*pkgname*.pot’ containing the translatable messages in the C/C++ files. If there is a src/windows directory, files within it are also examined.

- All existing files in directory `po` with names `'lang.po'` are updated from `'pkgname.pot'`, `checkPoFile` is called on the updated file, and if there are no problems the file is compiled and installed under `'inst/po'`.
- In a UTF-8 locale, a 'translation' `'en@quot.po'` is created with UTF-8 directional quotes, compiled and installed under `'inst/po'`.

Note that C/C++ messages are not automatically prepared for translation as they need to be explicitly marked for translation in the source files. Once that has been done, create an empty file `'po/pkgname.pot'` in the package sources and run this function again.

`pkg = "base"` is special (and for use by R developers only): the C files are not in the package directory but in the main sources.

### System requirements

This function requires the following tools from the GNU `gettext-tools`: `xgettext`, `msgmerge`, `msgfmt`, `msginit` and `msgconv`. These are part of most Linux distributions and easily compiled from the sources on Unix-alikes (including macOS). Pre-compiled versions for Windows are available in <https://www.stats.ox.ac.uk/pub/Rtools/goodies/gettext-tools.zip>.

It will probably not work correctly for `en@quot` translations except in a UTF-8 locale, so these are skipped elsewhere.

---

userdir

*R User Directories*

---

### Description

Directories for storing R-related user-specific data, configuration and cache files.

### Usage

```
R_user_dir(package, which = c("data", "config", "cache"))
```

### Arguments

|                      |  |
|----------------------|--|
| <code>package</code> | a character string giving the name of an R package                                 |
| <code>which</code>   | a character string indicating the kind of file(s) of interest. Can be abbreviated. |

### Details

For desktop environments using X Windows, the freedesktop.org project (formerly X Desktop Group, XDG) developed the XDG Base Directory Specification (<https://specifications.freedesktop.org/basedir-spec>) for standardizing the location where certain files should be placed. CRAN package **rappdirs** provides these general locations with appropriate values for all platforms for which R is available.

`R_user_dir` specializes the general mechanism to R package specific locations for user files, by providing package specific subdirectories inside a 'R' subdirectory inside the "base" directories

appropriate for user-specific data, configuration and cache files (see the examples), with the intent that packages will not interfere if they work within their respective subdirectories.

The locations of these base directories can be customized via the specific environment variables `R_USER_DATA_DIR`, `R_USER_CONFIG_DIR` and `R_USER_CACHE_DIR`. If these are not set, the general XDG-style environment variables `XDG_DATA_HOME`, `XDG_CONFIG_HOME` and `XDG_CACHE_HOME` are used if set, and otherwise, defaults appropriate for the R platform in use are employed.

## Examples

```
R_user_dir("FOO", "cache")

## Create one, platform agnostically, must work if <normal> :
(Rdb <- R_user_dir("base"))
if(newD <- !dir.exists(Rdb)) # should work user specifically:
  newD <- dir.create(Rdb, recursive=TRUE)
dir(Rdb) # typically empty
if(newD) unlink(Rdb) # cleaning up

list.files(R_user_dir("grid"), full.names = TRUE)
```

---

vignetteEngine

*Set or Get a Vignette Processing Engine*

---

## Description

Vignettes are normally processed by [Sweave](#), but package writers may choose to use a different engine (e.g., one provided by the **knitr**, **noweb** or **R.rsp** packages). This function is used by those packages to register their engines, and internally by R to retrieve them.

## Usage

```
vignetteEngine(name, weave, tangle, pattern = NULL,
               package = NULL, aspell = list())
```

## Arguments

|                      |   |
|----------------------|---|
| <code>name</code>    | the name of the engine.   |
| <code>weave</code>   | a function to convert vignette source files to PDF/HTML or intermediate LaTeX output.   |
| <code>tangle</code>  | a function to convert vignette source files to R code.  |
| <code>pattern</code> | a regular expression pattern for the filenames handled by this engine, or <code>NULL</code> for the default pattern.  |
| <code>package</code> | the package registering the engine. By default, this is the package calling <code>vignetteEngine</code> .   |
| <code>aspell</code>  | a list with element names <code>filter</code> and/or <code>control</code> giving the respective arguments to be used when spell checking the text in the vignette source file with <a href="#">aspell</a> . |

## Details

If `weave` is missing, `vignetteEngine` will return the currently registered engine matching name and package.

If `weave` is `NULL`, the specified engine will be deleted.

Other settings define a new engine. The `weave` and `tangle` functions must be defined with argument lists compatible with `function(file, ...)`. Currently the `...` arguments may include logical argument `quiet` and character argument `encoding`; others may be added in future. These are described in the documentation for [Sweave](#) and [Stangle](#).

The `weave` and `tangle` functions should return the filename of the output file that has been produced. Currently the `weave` function, when operating on a file named '`<name><pattern>`', must produce a file named '`<name>[.] (tex|pdf|html)`'. The '`.tex`' files will be processed by `pdflatex` to produce '`.pdf`' output for display to the user; the others will be displayed as produced. The `tangle` function must produce a file named '`<name>[.] [rRsS]`' containing the executable R code from the vignette. The `tangle` function may support a `split = TRUE` argument, and then it should produce files named '`<name>.*[.] [rRsS]`'.

The `pattern` argument gives a regular expression to match the extensions of files which are to be processed as vignette input files. If set to `NULL`, the default pattern "`[.] [RrSs] (nw|tex) $"` is used.

## Value

If the engine is being deleted, `NULL`. Otherwise a list containing components

|                      |                                      |
|----------------------|--------------------------------------|
| <code>name</code>    | The name of the engine               |
| <code>package</code> | The name of its package              |
| <code>pattern</code> | The pattern for vignette input files |
| <code>weave</code>   | The weave function                   |
| <code>tangle</code>  | The tangle function                  |

[Sweave](#) and the 'Writing R Extensions' manual.

## Examples

```
str(vignetteEngine("Sweave"))
```

vignetteInfo

*Basic Information about a Vignette***Description**

Extract metadata from a vignette source file.

**Usage**

```
vignetteInfo(file)
```

**Arguments**

`file` file name of the vignette.

**Value**

A [list](#) with the following [character](#) components:

|                       |  |
|-----------------------|--|
| <code>file</code>     | the <a href="#">basename</a> of the file.  |
| <code>title</code>    | the vignette title from ‘\VignetteIndexEntry’, possibly an empty string.                                   |
| <code>depends</code>  | a vector of package dependencies from ‘\VignetteDepends’, possibly of length 0.                            |
| <code>keywords</code> | a vector of keywords from ‘\VignetteKeyword’, possibly of length 0.  |
| <code>engine</code>   | the <a href="#">vignetteEngine</a> , such as <code>"utils::Sweave"</code> or <code>"knitr::knitr"</code> . |

**See Also**

[package\\_dependencies](#) for recursive dependencies.

**Examples**

```
gridEx <- system.file("doc", "grid.Rnw", package = "grid")
vi <- vignetteInfo(gridEx)
str(vi)
```

write\_PACKAGES

*Generate PACKAGES Files***Description**

Generate ‘PACKAGES’, ‘PACKAGES.gz’ and ‘PACKAGES.rds’ files for a repository of source or Mac/Windows binary packages.

**Usage**

```
write_PACKAGES(dir = ".", fields = NULL,
               type = c("source", "mac.binary", "win.binary"),
               verbose = FALSE, unpacked = FALSE, subdirs = FALSE,
               latestOnly = TRUE, addFiles = FALSE, rds_compress = "xz",
               validate = FALSE)
```

**Arguments**

|                           |   |
|---------------------------|---|
| <code>dir</code>          | Character vector describing the location of the repository (directory including source or binary packages) to generate the ‘PACKAGES’, ‘PACKAGES.gz’ and ‘PACKAGES.rds’ files from and write them to.   |
| <code>fields</code>       | a character vector giving the fields to be used in the ‘PACKAGES’, ‘PACKAGES.gz’ and ‘PACKAGES.rds’ files in addition to the default ones, or NULL (default).<br>The default corresponds to the fields needed by <a href="#">available.packages</a> : "Package", "Version", "Priority", "Depends", "Imports", "LinkingTo", "Suggests", "Enhances", "OS_type", "License" and "Archs", and those fields will always be included, plus the file name in field "File" if <code>addFile = TRUE</code> and the path to the subdirectory in field "Path" if subdirectories are used. |
| <code>type</code>         | Type of packages: currently source ‘.tar.{gz,bz2,xz}’ archives, and macOS or Windows binary (‘.tgz’ or ‘.zip’, respectively) packages are supported. Defaults to "win.binary" on Windows and to "source" otherwise.   |
| <code>verbose</code>      | logical. Should packages be listed as they are processed?   |
| <code>unpacked</code>     | a logical indicating whether the package contents are available in unpacked form or not (default).  |
| <code>subdirs</code>      | either logical (to indicate if subdirectories should be included, recursively) or a character vector of names of subdirectories to include (which are not recursed).  |
| <code>latestOnly</code>   | logical: if multiple versions of a package are available should only the latest version be included?  |
| <code>addFiles</code>     | logical: should the filenames be included as field ‘File’ in the ‘PACKAGES’ file.   |
| <code>rds_compress</code> | The type of compression to be used for ‘PACKAGES.rds’: see <a href="#">saveRDS</a> . The default is the one found to give maximal compression, and is as used on CRAN.  |
| <code>validate</code>     | a logical indicating whether ‘DESCRIPTION’ files should be validated, and the corresponding packages skipped in case this finds problems.   |

**Details**

`write_PACKAGES` scans the named directory for R packages, extracts information from each package’s ‘DESCRIPTION’ file, and writes this information into the ‘PACKAGES’, ‘PACKAGES.gz’ and ‘PACKAGES.rds’ files, where the first two represent the information in DCF format, and the third serializes it via [saveRDS](#).

Including non-latest versions of packages is only useful if they have less constraining version requirements, so for example `latestOnly = FALSE` could be used for a source repository when ‘foo\_1.0’ depends on ‘R >= 2.15.0’ but ‘foo\_0.9’ is available which depends on ‘R >= 2.11.0’.

Support for repositories with subdirectories and hence for `subdirs != FALSE` depends on recording a "Path" field in the 'PACKAGES' files.

Support for more general file names (e.g., other types of compression) *via* a "File" field in the 'PACKAGES' files can be used by [download.packages](#). If the file names are not of the standard form, use `addFiles = TRUE`.

`type = "win.binary"` uses [unz](#) connections to read all 'DESCRIPTION' files contained in the (zipped) binary packages for Windows in the given directory `dir`, and builds files 'PACKAGES', 'PACKAGES.gz' and 'PACKAGES.rds' files from this information.

For a remote repository there is a tradeoff between download speed and time spent by [available.packages](#) processing the downloaded file(s). For large repositories it is likely to be beneficial to use `rds_compress = "xz"`.

### Value

Invisibly returns the number of packages described in the resulting 'PACKAGES', 'PACKAGES.gz' and 'PACKAGES.rds' files. If 0, no packages were found and no files were written.

### Note

Processing '.tar.gz' archives to extract the 'DESCRIPTION' files is quite slow.

This function can be useful on other OSes to prepare a repository to be accessed by Windows machines, so `type = "win.binary"` should work on all OSes.

### Author(s)

Uwe Ligges and R-core.

### See Also

See [read.dcf](#) and [write.dcf](#) for reading 'DESCRIPTION' files and writing the 'PACKAGES' and 'PACKAGES.gz' files. See [update\\_PACKAGES](#) for efficiently updating existing 'PACKAGES' and 'PACKAGES.gz' files.

### Examples

```
## Not run:
write_PACKAGES("c:/myFolder/myRepository") # on Windows
write_PACKAGES("/pub/RWin/bin/windows/contrib/2.9",
               type = "win.binary") # on Linux

## End(Not run)
```

## Description

For each file in the ‘R’ directory (including system-specific subdirectories) of a *source* package, extract the unique arguments passed to these “message generating” calls;

**for** `xgettext()`: to `stop`, `warning`, `message`, `packageStartupMessage`, `gettext` and `gettextf`,

**for** `xngettext()`: to `ngettext`.

`xgettext2pot()` calls both `xgettext()` and then `xngettext()`.

## Usage

```
xgettext(dir, verbose = FALSE, asCall = TRUE)
```

```
xngettext(dir, verbose = FALSE)
```

```
xgettext2pot(dir, potFile, name = "R", version, bugs)
```

## Arguments

|                                  |   |
|----------------------------------|---|
| <code>dir</code>                 | the directory of a source package, i.e., with a ‘./R’ sub directory.  |
| <code>verbose</code>             | logical: should each file be listed as it is processed?   |
| <code>asCall</code>              | logical: if TRUE each argument is converted to string and returned whole, otherwise the string literals within each argument are extracted (recursively). See Examples. |
| <code>potFile</code>             | name of po template file to be produced. Defaults to ‘R- <i>pkgname</i> .pot’ where <i>pkgname</i> is the basename of ‘dir’.  |
| <code>name, version, bugs</code> | as recorded in the template file: <code>version</code> defaults the version number of the currently running R, and <code>bugs</code> to “bugs.r-project.org”.           |

## Details

Leading and trailing white space (space, tab and linefeed (aka newline, i.e., ‘\n’)) is removed for all the calls extracted by `xgettext()`, see ‘Description’ above, as it is by the internal code that passes strings for translation.

We look to see if the matched functions were called with `domain = NA`. If so, when `asCall` is true, the whole call is omitted. Note that a call might contain a nested call to `gettext` (or `warning`, etc.) whose strings would be visible if `asCall` is false.

`xgettext2pot` calls `xgettext` and then `xngettext`, and writes a PO template file (to `potFile`) for use with the **GNU Gettext** tools. This ensures that the strings for simple translation are unique in the file (as **GNU Gettext** requires), but does not do so for `ngettext` calls (and the rules are not stated in the Gettext manual, but `msgfmt` complains if there is duplication between the sets.).

If applied to the **base** package, this also looks in the ‘.R’ files in ‘[R\\_HOME](#)/share/R’.

## Value

For `xgettext`, a list of objects of class “xgettext” (which has a `print` method), one per source file that contains potentially translatable strings.

For `xngettext`, a list of objects of class “xngettext”, which are themselves lists of length-2 character vectors.

**See Also**

[update\\_pkg\\_po\(\)](#) which calls `xgettext2pot()`.

**Examples**

```
## Not run: ## in a source-directory build (not typical!) of R;
## otherwise, download and unpack the R sources, and replace
## R.home() by "<my_path_to_source_R>" :
xgettext(file.path(R.home(), "src", "library", "splines"))

## End(Not run)

## Create source package-like <tmp>/R/foo.R and get text from it:
tmpPkg <- tempdir()
tmpRDir <- file.path(tmpPkg, "R")
dir.create(tmpRDir, showWarnings = FALSE)
fnChar <- paste(sep = "\n",
  "foo <- function(x) {",
  "  if (x < -1) stop('too small')",
  "  # messages unduplicated (not so for ngettext)",
  "  if (x < -.5) stop('too small')",
  "  if (x < 0) {",
  "    warning(",
  "      'sqrt(x) is', sqrt(as.complex(x)),",
  "      ', which may be too small'",
  "    )",
  "  }",
  "  # calls with domain=NA are skipped",
  "  if (x == 0) cat(gettext('x is 0!\n', domain=NA))",
  "  # gettext strings may be ignored due to 'outer' domain=NA",
  "  if (x > 10) warning('x is ', gettextf('%.2f', x), domain=NA)",
  "  # using a custom condition class",
  "  if (x == 42)",
  "    stop(errorCondition(gettext('needs Deep Thought'), class='myError'))",
  "  x",
  "}"
)

writeLines(fnChar, con = file.path(tmpRDir, "foo.R"))

## [[1]] : suppressing (tmpfile) name to make example Rdiff-able
xgettext(tmpPkg, asCall=TRUE)[[1]] # default; shows calls
xgettext(tmpPkg, asCall=FALSE)[[1]] # doesn't ; but then ' %.2f '

unlink(tmpRDir, recursive=TRUE)
```

## Chapter 14

# The `utils` package

---

`utils-package`

*The R Utils Package*

---

### Description

R utility functions

### Details

This package contains a collection of utility functions.

For a complete list, use `library(help = "utils")`.

### Author(s)

R Core Team and contributors worldwide

Maintainer: R Core Team <R-core@r-project.org>

---

`adist`

*Approximate String Distances*

---

### Description

Compute the approximate string distance between character vectors. The distance is a generalized Levenshtein (edit) distance, giving the minimal possibly weighted number of insertions, deletions and substitutions needed to transform one string into another.

### Usage

```
adist(x, y = NULL, costs = NULL, counts = FALSE, fixed = TRUE,
      partial = !fixed, ignore.case = FALSE, useBytes = FALSE)
```

## Arguments

|                          |  |
|--------------------------|--|
| <code>x</code>           | a character vector. <a href="#">Long vectors</a> are not supported.  |
| <code>y</code>           | a character vector, or <code>NULL</code> (default) indicating taking <code>x</code> as <code>y</code> .  |
| <code>costs</code>       | a numeric vector or list with names partially matching ‘insertions’, ‘deletions’ and ‘substitutions’ giving the respective costs for computing the Levenshtein distance, or <code>NULL</code> (default) indicating using unit cost for all three possible transformations.   |
| <code>counts</code>      | a logical indicating whether to optionally return the transformation counts (numbers of insertions, deletions and substitutions) as the “counts” attribute of the return value.  |
| <code>fixed</code>       | a logical. If <code>TRUE</code> (default), the <code>x</code> elements are used as string literals. Otherwise, they are taken as regular expressions and <code>partial = TRUE</code> is implied (corresponding to the approximate string distance used by <a href="#">agrep</a> with <code>fixed = FALSE</code> ). |
| <code>partial</code>     | a logical indicating whether the transformed <code>x</code> elements must exactly match the complete <code>y</code> elements, or only substrings of these. The latter corresponds to the approximate string distance used by <a href="#">agrep</a> (by default).   |
| <code>ignore.case</code> | a logical. If <code>TRUE</code> , case is ignored for computing the distances.   |
| <code>useBytes</code>    | a logical. If <code>TRUE</code> distance computations are done byte-by-byte rather than character-by-character.  |

## Details

The (generalized) Levenshtein (or edit) distance between two strings  $s$  and  $t$  is the minimal possibly weighted number of insertions, deletions and substitutions needed to transform  $s$  into  $t$  (so that the transformation exactly matches  $t$ ). This distance is computed for `partial = FALSE`, currently using a dynamic programming algorithm (see, e.g., [https://en.wikipedia.org/wiki/Levenshtein\\_distance](https://en.wikipedia.org/wiki/Levenshtein_distance)) with space and time complexity  $O(mn)$ , where  $m$  and  $n$  are the lengths of  $s$  and  $t$ , respectively. Additionally computing the transformation sequence and counts is  $O(\max(m, n))$ .

The generalized Levenshtein distance can also be used for approximate (fuzzy) string matching, in which case one finds the substring of  $t$  with minimal distance to the pattern  $s$  (which could be taken as a regular expression, in which case the principle of using the leftmost and longest match applies), see, e.g., [https://en.wikipedia.org/wiki/Approximate\\_string\\_matching](https://en.wikipedia.org/wiki/Approximate_string_matching). This distance is computed for `partial = TRUE` using ‘tre’ by Ville Laurikari (<https://github.com/laurikari/tre>) and corresponds to the distance used by [agrep](#). In this case, the given cost values are coerced to integer.

Note that the costs for insertions and deletions can be different, in which case the distance between  $s$  and  $t$  can be different from the distance between  $t$  and  $s$ .

## Value

A matrix with the approximate string distances of the elements of `x` and `y`, with rows and columns corresponding to `x` and `y`, respectively.

If `counts` is `TRUE`, the transformation counts are returned as the “counts” attribute of this matrix, as a 3-dimensional array with dimensions corresponding to the elements of `x`, the elements of `y`, and the type of transformation (insertions, deletions and substitutions), respectively. Additionally, if `partial = FALSE`, the transformation sequences are returned as the “trafos” attribute of the return value, as character strings with elements ‘M’, ‘I’, ‘D’ and ‘S’ indicating a match, insertion, deletion and substitution, respectively. If `partial = TRUE`, the offsets (positions of the first

and last element) of the matched substrings are returned as the "offsets" attribute of the return value (with both offsets  $-1$  in case of no match).

### See Also

[agrep](#) for approximate string matching (fuzzy matching) using the generalized Levenshtein distance.

### Examples

```
## Cf. https://en.wikipedia.org/wiki/Levenshtein_distance
adist("kitten", "sitting")
## To see the transformation counts for the Levenshtein distance:
drop(attr(adist("kitten", "sitting", counts = TRUE), "counts"))
## To see the transformation sequences:
attr(adist(c("kitten", "sitting"), counts = TRUE), "trafos")

## Cf. the examples for agrep:
adist("lasy", "1 lazy 2")
## For a "partial approximate match" (as used for agrep):
adist("lasy", "1 lazy 2", partial = TRUE)
```

---

alarm

*Alert the User*

---

### Description

Gives an audible or visual signal to the user.

### Usage

```
alarm()
```

### Details

`alarm()` works by sending a `"\a"` character to the console. On most platforms this will ring a bell, beep, or give some other signal to the user (unless standard output has been redirected).

It attempts to flush the console (see [flush.console](#)).

### Value

No useful value is returned.

### Examples

```
alarm()
```

apropos

*Find Objects by (Partial) Name***Description**

`apropos()` returns a character vector giving the names of objects in the search list matching (as a regular expression) `what`.

`find()` returns where objects of a given name can be found.

**Usage**

```
apropos(what, where = FALSE, ignore.case = TRUE,
        dot_internals = FALSE, mode = "any")
```

```
find(what, mode = "any", numeric = FALSE, simple.words = TRUE)
```

**Arguments**

|                             |  |
|-----------------------------|--|
| <code>what</code>           | character string. For <code>simple.words = FALSE</code> the name of an object; otherwise a <a href="#">regular expression</a> to match object names against. |
| <code>where, numeric</code> | a logical indicating whether positions in the search list should also be returned  |
| <code>ignore.case</code>    | logical indicating if the search should be case-insensitive, TRUE by default.  |
| <code>dot_internals</code>  | logical indicating if the search result should show <b>base</b> internal objects, FALSE by default.  |
| <code>mode</code>           | character; if not "any", only objects whose <a href="#">mode</a> equals <code>mode</code> are searched.  |
| <code>simple.words</code>   | logical; if TRUE, the <code>what</code> argument is only searched as a whole word.   |

**Details**

If `mode != "any"` only those objects which are of `mode` are considered.

`find` is a different user interface for a similar task to `apropos`. By default (`simple.words == TRUE`), only whole names are matched. Unlike `apropos`, matching is always case-sensitive.

Unlike the default behaviour of [ls](#), names which begin with a `'.'` are included, but base 'internal' objects are included only when `dot_internals` is true.

**Value**

For `apropos`, a character vector sorted by name. For `where = TRUE` this has names giving the (numerical) positions on the search path.

For `find`, either a character vector of environment names or (for `numeric = TRUE`) a numerical vector of positions on the search path with names the names of the corresponding environments.

**Author(s)**

Originally, Kurt Hornik and Martin Maechler (May 1997).

**See Also**

[glob2rx](#) to convert wildcard patterns to regular expressions.

[objects](#) for listing objects from one place, [help.search](#) for searching the help system, [search](#) for the search path.

**Examples**

```
require(stats)

## Not run: apropos("lm")
apropos("GLM")                # several
apropos("GLM", ignore.case = FALSE) # not one
apropos("lq")

cor <- 1:pi
find("cor")                   #> ".GlobalEnv"    "package:stats"
find("cor", numeric = TRUE)   # numbers with these names
find("cor", numeric = TRUE, mode = "function") # only the second one
rm(cor)

## Not run: apropos(".", mode = "list") # includes many datasets

# extraction/replacement methods (need a DOUBLE backslash '\\')
apropos("\\[")

# everything % not diff-able
length(apropos("."))

# those starting with 'pr'
apropos("^pr")

# the 1-letter things
apropos("^.?$")
# the 1-2-letter things
apropos("^.?.$")
# the 2-to-4 letter things
apropos("^{2,4}$")
# frequencies of 8-and-more letter things
table(nchar(apropos("^{8,}$")))
```

aregexec

*Approximate String Match Positions***Description**

Determine positions of approximate string matches.

**Usage**

```
aregexec(pattern, text, max.distance = 0.1, costs = NULL,
          ignore.case = FALSE, fixed = FALSE, useBytes = FALSE)
```

## Arguments

|                           |   |
|---------------------------|---|
| <code>pattern</code>      | a non-empty character string or a character string containing a regular expression (for <code>fixed = FALSE</code> ) to be matched. Coerced by <code>as.character</code> to a string if possible. |
| <code>text</code>         | character vector where matches are sought. Coerced by <code>as.character</code> to a character vector if possible.  |
| <code>max.distance</code> | maximum distance allowed for a match. See <code>agrep</code> .  |
| <code>costs</code>        | cost of transformations. See <code>agrep</code> .   |
| <code>ignore.case</code>  | a logical. If <code>TRUE</code> , case is ignored for computing the distances.  |
| <code>fixed</code>        | If <code>TRUE</code> , the pattern is matched literally (as is). Otherwise (default), it is matched as a regular expression.  |
| <code>useBytes</code>     | a logical. If <code>TRUE</code> comparisons are byte-by-byte rather than character-by-character.  |

## Details

`aregexec` provides a different interface to approximate string matching than `agrep` (along the lines of the interfaces to exact string matching provided by `regexec` and `grep`).

Note that by default, `agrep` performs literal matches, whereas `aregexec` performs regular expression matches.

See `agrep` and `adist` for more information about approximate string matching and distances.

Comparisons are byte-by-byte if `pattern` or any element of `text` is marked as `"bytes"`.

## Value

A list of the same length as `text`, each element of which is either `-1` if there is no match, or a sequence of integers with the starting positions of the match and all substrings corresponding to parenthesized subexpressions of `pattern`, with attribute `"match.length"` an integer vector giving the lengths of the matches (or `-1` for no match).

## See Also

`regmatches` for extracting the matched substrings.

## Examples

```
## Cf. the examples for agrep.
x <- c("1 lazy", "1", "1 LAZY")
aregexec("laysy", x, max.distance = 2)
aregexec("(lay)(sy)", x, max.distance = 2)
aregexec("(lay)(sy)", x, max.distance = 2, ignore.case = TRUE)
m <- aregexec("(lay)(sy)", x, max.distance = 2)
regmatches(x, m)
```

---

|                |  |
|----------------|--|
| arrangeWindows | <i>Rearrange Windows on MS Windows</i> |
|----------------|--|

---

## Description

This function allows you to tile or cascade windows, or to minimize or restore them (on Windows, i.e. when (`.Platform$OS.type == "windows"`)). This may include windows not “belonging” to R.

## Usage

```
arrangeWindows(action, windows, preserve = TRUE, outer = FALSE)
```

## Arguments

|                       |  |
|-----------------------|--|
| <code>action</code>   | a character string, the action to perform on the windows. The choices are <code>c("vertical", "horizontal", "cascade", "minimize", "restore")</code> with default <code>"vertical"</code> ; see the ‘Details’ for the interpretation. Abbreviations may be used. |
| <code>windows</code>  | a <a href="#">list</a> of window handles, by default produced by <code>getWindowsHandles()</code> .  |
| <code>preserve</code> | If <code>TRUE</code> , when tiling preserve the outer boundary of the collection of windows; otherwise make them as large as will fit.   |
| <code>outer</code>    | This argument is only used in MDI mode. If <code>TRUE</code> , tile the windows on the system desktop. Otherwise, tile them within the MDI frame.  |

## Details

The actions are as follows:

`"vertical"` Tile vertically.

`"horizontal"` Tile horizontally.

`"cascade"` Cascade the windows.

`"minimize"` Minimize all of the windows.

`"restore"` Restore all of the windows to normal size (not minimized, not maximized).

The tiling and cascading are done by the standard Windows API functions, but unlike those functions, they will apply to all of the windows in the `windows` list.

By default, `windows` is set to the result of `getWindowsHandles()` (with one exception described below). This will select windows belonging to the current R process. However, if the global environment contains a variable named `.arrangeWindowsDefaults`, it will be used as the argument list instead. See the `getWindowsHandles` man page for a discussion of the optional arguments to that function.

When `action = "restore"` is used with `windows` unspecified, `minimized = TRUE` is added to the argument list of `getWindowsHandles` so that minimized windows will be restored.

In MDI mode, by default tiling and cascading will happen within the R GUI frame. However, if `outer = TRUE`, tiling is done on the system desktop. This will generally not give desirable results if any R child windows are included within `windows`.

**Value**

This function is called for the side effect of arranging the windows. The list of window handles is returned invisibly.

**Note**

This is only available on Windows.

**Author(s)**

Duncan Murdoch

**See Also**

[getWindowsHandles](#)

**Examples**

```
## Not run: ## Only available on Windows :
arrangeWindows("v")
# This default is useful only in SDI mode: it will tile any Firefox window
# along with the R windows
.arrangeWindowsDefaults <- list(c("R", "all"), pattern = c("", "Firefox"))
arrangeWindows("v")

## End(Not run)
```

---

askYesNo

*Ask a Yes/No Question*

---

**Description**

askYesNo provides a standard way to ask the user a yes/no question. It provides a way for front-ends to substitute their own dialogs.

**Usage**

```
askYesNo(msg, default = TRUE,
         prompts = getOption("askYesNo", gettext(c("Yes", "No", "Cancel"))),
         ...)
```

**Arguments**

|         |  |
|---------|--|
| msg     | The prompt message for the user.   |
| default | The default response.  |
| prompts | Any of: a character vector containing 3 prompts corresponding to return values of TRUE, FALSE, or NA, or a single character value containing the prompts separated by / characters, or a function to call. |
| ...     | Additional parameters, ignored by the default function.  |

Details

askYesNo will accept case-independent partial matches to the prompts. If no response is given the value of default will be returned; if a non-empty string that doesn't match any of the prompts is entered, an error will be raised.

If a function or single character string naming a function is given for prompts, it will be called as fn(msg=msg, default=default, prompts=prompts, ...). On Windows, the GUI uses the unexported utils::askYesNoWinDialog function for this purpose.

If strings (or a string such as "Y/N/C") are given as prompts, the choices will be mapped to lowercase for the non-default choices, and left as-is for the default choice.

Value

TRUE for yes, FALSE for no, and NA for cancel.

See Also

readline for more general user input.

Examples

```
if (interactive())
  askYesNo("Do you want to use askYesNo?")
```

---

|        |                              |
|--------|------------------------------|
| aspell | <i>Spell Check Interface</i> |
|--------|------------------------------|

---

Description

Spell check given files via Aspell, Hunspell or Ispell.

Usage

```
aspell(files, filter, control = list(), encoding = "unknown",
       program = NULL, dictionaries = character())
```

Arguments

- files            a character vector with the names of files to be checked.
- filter          an optional filter for processing the files before spell checking, given as either a function (with formals ifile and encoding), or a character string specifying a built-in filter, or a list with the name of a built-in filter and additional arguments to be passed to it. See **Details** for available filters. If missing or NULL, no filtering is performed.
- control        a list or character vector of control options for the spell checker.
- encoding       the encoding of the files. Recycled as needed.
- program        a character string giving the name (if on the system path) or full path of the spell check program to be used, or NULL (default). By default, the system path is searched for aspell, hunspell and ispell (in that order), and the first one found is used.

`dictionaries` a character vector of names or file paths of additional R level dictionaries to use. Elements with no path separator specify R system dictionaries (in subdirectory ‘share/dictionaries’ of the R home directory). The file extension (currently, only ‘.rds’) can be omitted.

## Details

The spell check programs employed must support the so-called Ispell pipe interface activated via command line option ‘-a’. In addition to the programs, suitable dictionaries need to be available. See <http://aspell.net>, <https://hunspell.github.io/> and <https://www.cs.hmc.edu/~geoff/ispell.html>, respectively, for obtaining the Aspell, Hunspell and (International) Ispell programs and dictionaries.

On Windows, Aspell is available via MSYS2. One should use a non-Cygwin version, e.g. package `mingw-w64-x86_64-aspell`. The version built against the Cygwin runtime (package `aspell`) requires Unix line endings in files and Unix-style paths, which is incompatible with `aspell()`.

The currently available built-in filters are “Rd” (corresponding to `RdTextFilter`, with additional argument `ignore` allowing to give regular expressions for parts of the text to be ignored for spell checking), “Sweave” (corresponding to `SweaveTexFilter`), “R”, “pot”, “dcf” and “md”.

Filter “R” is for R code and extracts the message string constants in calls to `message`, `warning`, `stop`, `packageStartupMessage`, `gettext`, `gettextf`, and `ngettext` (the unnamed string constants for the first five, and `fmt` and `msg1/msg2` string constants, respectively, for the latter two).

Filter “pot” is for message string catalog ‘.pot’ files. Both have an argument `ignore` allowing to give regular expressions for parts of message strings to be ignored for spell checking: e.g., using `"[\\t]'[^']*'[\\t[:punct:]]"` ignores all text inside single quotes.

Filter “dcf” is for files in Debian Control File format. The fields to keep can be controlled by argument `keep` (a character vector with the respective field names). By default, ‘Title’ and ‘Description’ fields are kept.

Filter “md” is for files in **Markdown** format (‘.md’ and ‘.Rmd’ files), and needs packages **commonmark** and **xm12** to be available.

The print method for the objects returned by `aspell` has an `indent` argument controlling the indentation of the positions of possibly misspelled words. The default is 2; Emacs users may find it useful to use an indentation of 0 and visit output in `grep`-mode. It also has a `verbose` argument: when this is true, suggestions for replacements are shown as well.

It is possible to employ additional R level dictionaries. Currently, these are files with extension ‘.rds’ obtained by serializing character vectors of word lists using `saveRDS`. If such dictionaries are employed, they are combined into a single word list file which is then used as the spell checker’s personal dictionary (option ‘-p’): hence, the default personal dictionary is not used in this case.

## Value

A data frame inheriting from `aspell` (which has a useful print method) with the information about possibly misspelled words.

## References

**Examples**

```
## Not run:
## To check all Rd files in a directory, (additionally) skipping the
## \references sections.
files <- Sys.glob("*.Rd")
aspell(files, filter = list("Rd", drop = "\\references"))

## To check all Sweave files
files <- Sys.glob(c("*.Rnw", "*.Snw", "*.rnw", "*.snw"))
aspell(files, filter = "Sweave", control = "-t")

## To check all Texinfo files (Aspell only)
files <- Sys.glob("*.texi")
aspell(files, control = "--mode=texinfo")

## End(Not run)

## List the available R system dictionaries.
Sys.glob(file.path(R.home("share"), "dictionaries", "*.rds"))
```

aspell-utils

*Spell Check Utilities*

---

**Description**

Utilities for spell checking packages via Aspell, Hunspell or Ispell.

**Usage**

```
aspell_package_Rd_files(dir,
                        drop = c("\\abbr", "\\acronym",
                                "\\author", "\\references"),
                        control = list(), program = NULL,
                        dictionaries = character())
aspell_package_vignettes(dir,
                        control = list(), program = NULL,
                        dictionaries = character())
aspell_package_R_files(dir, ignore = character(), control = list(),
                      program = NULL, dictionaries = character())
aspell_package_C_files(dir, ignore = character(), control = list(),
                      program = NULL, dictionaries = character())

aspell_write_personal_dictionary_file(x, out, language = "en",
                                     program = NULL)
```

## Arguments

|                           |  |
|---------------------------|--|
| <code>dir</code>          | a character string specifying the path to a package's root directory.  |
| <code>drop</code>         | a character vector naming additional Rd sections to drop when selecting text via <a href="#">RdTextFilter</a> .  |
| <code>control</code>      | a list or character vector of control options for the spell checker.   |
| <code>program</code>      | a character string giving the name (if on the system path) or full path of the spell check program to be used, or <code>NULL</code> (default). By default, the system path is searched for <code>aspell</code> , <code>hunspell</code> and <code>ispell</code> (in that order), and the first one found is used. |
| <code>dictionaries</code> | a character vector of names or file paths of additional R level dictionaries to use. See <a href="#">aspell</a> .  |
| <code>ignore</code>       | a character vector with regular expressions to be replaced by blanks when filtering the message strings.   |
| <code>x</code>            | a character vector, or the result of a call to <a href="#">aspell()</a> .  |
| <code>out</code>          | a character string naming the personal dictionary file to write to.  |
| <code>language</code>     | a character string indicating a language as used by Aspell.  |

## Details

Functions `aspell_package_Rd_files`, `aspell_package_vignettes`, `aspell_package_R_files` and `aspell_package_C_files` perform spell checking on the Rd files, vignettes, R files, and C-level messages of the package with root directory `dir`. They determine the respective files, apply the appropriate filters, and run the spell checker.

See [aspell](#) for details on filters.

The C-level message string are obtained from the `'po/PACKAGE.pot'` message catalog file, with `PACKAGE` the basename of `dir`. See the section on 'C-level messages' in 'Writing R Extensions' for more information.

When using Aspell, the vignette checking skips parameters and/or options of commands `\Sexpr`, `\citep`, `\code`, `\pkg`, `\proglang` and `\samp` (in addition to the what the Aspell TeX/L<sup>A</sup>T<sub>E</sub>X filter skips by default). Further commands can be skipped by adding `--add-tex-command` options to the `control` argument. E.g., to skip both option and parameter of `\mycmd`, add `--add-tex-command='mycmd op'`.

Suitable values for `control`, `program`, `dictionaries`, `drop` and `ignore` can also be specified using a package defaults file which should go as `'defaults.R'` into the `'aspell'` subdirectory of `dir`, and provides defaults via assignments of suitable named lists, e.g.,

```
vignettes <- list(control = "--add-tex-command='mycmd op'")
```

for vignettes (when using Aspell) and similarly assigning to `Rd_files`, `R_files` and `C_files` for Rd files, R files and C level message defaults.

Maintainers of packages using both English and American spelling will find it convenient to pass control options `--master=en_US` and `--add-extra-dicts=en_GB` to Aspell and control options `-den_US,en_GB` to Hunspell (provided that the corresponding dictionaries are installed).

Older versions of R had no support for R level dictionaries, and hence provided the function `aspell_write_personal_dictionary_file` to create (spell check) program-specific personal dictionary files from words to be accepted. The new mechanism is to use R level dictionaries, i.e., `'rds'` files obtained by serializing character vectors of such words using [saveRDS](#). For such dictionaries specified via the package defaults mechanism, elements with no path separator can be R system dictionaries or dictionaries in the `'aspell'` subdirectory.

**See Also**[aspell](#)

---

 available.packages *List Available Packages at CRAN-like Repositories*

---

**Description**

`available.packages` returns a matrix of details corresponding to packages currently available at one or more repositories. The current list of packages is downloaded over the internet (or copied from a local mirror).

**Usage**

```
available.packages(contriburl = contrib.url(repos, type), method,
                  fields = NULL, type = getOption("pkgType"),
                  filters = NULL, repos = getOption("repos"),
                  ignore_repo_cache = FALSE, max_repo_cache_age,
                  quiet = TRUE, ...)
```

**Arguments**

|                                 |   |
|---------------------------------|---|
| <code>contriburl</code>         | URL(s) of the ‘contrib’ sections of the repositories. Specify this argument only if your repository mirror is incomplete, e.g., because you mirrored only the ‘contrib’ section.                  |
| <code>method</code>             | download method, see <a href="#">download.file</a> .  |
| <code>type</code>               | character string, indicate which type of packages: see <a href="#">install.packages</a> . If <code>type = "both"</code> this will use the source repository.                                      |
| <code>fields</code>             | a character vector giving the fields to extract from the ‘PACKAGES’ file(s) in addition to the default ones, or <code>NULL</code> (default). Unavailable fields result in <code>NA</code> values. |
| <code>filters</code>            | a character vector or list or <code>NULL</code> (default). See ‘Details’.   |
| <code>repos</code>              | character vector, the base URL(s) of the repositories to use.   |
| <code>ignore_repo_cache</code>  | logical. If true, the repository cache is never used (see ‘Details’).   |
| <code>max_repo_cache_age</code> | any cached values older than this in seconds will be ignored. See ‘Details’.  |
| <code>quiet</code>              | logical, passed to <a href="#">download.file()</a> ; change only if you know what you are doing.  |
| <code>...</code>                | allow additional arguments to be passed from callers (which might be arguments to future versions of this function). Currently these are all passed to <a href="#">download.file()</a> .          |

## Details

The list of packages is either copied from a local mirror (specified by a `'file://'` URI) or downloaded. If downloaded and `ignore_repo_cache` is false (the default), the list is cached for the R session in a per-repository file in `tempdir()` with a name like

```
repos_http%3a%2f%2fcran.r-project.org%2fsrc%2fcontrib.rds
```

The cached values are renewed when found to be too old, with the age limit controlled *via* argument `max_repo_cache_age`. This defaults to the current value of the environment variable `R_AVAILABLE_PACKAGES_CACHE_CONTROL_MAX_AGE`, or if unset, to 3600 (one hour).

By default, the return value includes only packages whose version and OS requirements are met by the running version of R, and only gives information on the latest versions of packages.

Argument `filters` can be used to select which of the packages on the repositories are reported. It is called with its default value (NULL) by functions such as `install.packages`; this value corresponds to `getOption("available_packages_filters")` and to `c("R_version", "OS_type", "subarch", "duplicates")` if that is unset or set to NULL.

The built-in filters are

"R\_version" Exclude packages whose R version requirements are not met.

"OS\_type" Exclude packages whose OS requirement is incompatible with this version of R: that is exclude Windows-only packages on a Unix-alike platform and *vice versa*.

"subarch" For binary packages, exclude those with compiled code that is not available for the current sub-architecture, e.g. exclude packages only compiled for 32-bit Windows on a 64-bit Windows R.

"duplicates" Only report the latest version where more than one version is available, and only report the first-named repository (in `contriburl`) with the latest version if that is in more than one repository.

"license/FOSS" Include only packages for which installation can proceed solely based on packages which can be verified as Free or Open Source Software (FOSS, e.g., <https://en.wikipedia.org/wiki/FOSS>) employing the available license specifications. Thus both the package and any packages that it depends on to load need to be *known to be* FOSS.

Note that this does depend on the repository supplying license information.

"license/restricts\_use" Include only packages for which installation can proceed solely based on packages which are known not to restrict use.

"CRAN" Use CRAN versions in preference to versions from other repositories (even if these have a higher version number). This needs to be applied *before* the default "duplicates" filter, so cannot be used with `add = TRUE`.

If all the filters are from this set, then they can be specified as a character vector; otherwise `filters` should be a list with elements which are character strings, user-defined functions or `add = TRUE` (see below).

User-defined filters are functions which take a single argument, a matrix of the form returned by `available.packages`, and return a matrix consisting of a subset of the rows of the argument.

The special 'filter' `add = TRUE` appends the other elements of the filter list to the default filters.

## Value

A character matrix with one row per package, row names the package names and column names including "Package", "Version", "Priority", "Depends", "Imports",

"LinkingTo", "Suggests", "Enhances", "File" and "Repository". Additional columns can be specified using the `fields` argument.

Where provided by the repository, fields "OS\_type", "License", "License\_is\_FOSS", "License\_restricts\_use", "Archs", "MD5sum" and "NeedsCompilation" are re-reported for use by the filters and package management tools, including `install.packages`.

### See Also

`packageStatus`, `update.packages`, `install.packages`, `download.packages`, `contrib.url`.

The ‘R Installation and Administration’ manual for how to set up a repository.

### Examples

```
## Count package licenses
db <- available.packages(repos = findCRANmirror("web"), filters = "duplicates")
table(db[, "License"])

## Use custom filter function to only keep recommended packages
## which do not require compilation
available.packages(repos = findCRANmirror("web"),
  filters = list(
    add = TRUE,
    function (db) db[db[, "Priority"] %in% "recommended" &
      db[, "NeedsCompilation"] == "no", ]
  )
)

## Not run:
## Restrict install.packages() (etc) to known-to-be-FOSS packages
options(available_packages_filters =
  c("R_version", "OS_type", "subarch", "duplicates", "license/FOSS"))
## or
options(available_packages_filters = list(add = TRUE, "license/FOSS"))

## Give priority to released versions on CRAN, rather than development
## versions on R-Forge etc.
options(available_packages_filters =
  c("R_version", "OS_type", "subarch", "CRAN", "duplicates"))

## End(Not run)
```

---

BATCH

*Batch Execution of R*

---

### Description

Run R non-interactively with input from `infile` and send output (stdout/stderr) to another file.

### Usage

```
R CMD BATCH [options] infile [outfile]
```

**Arguments**

|                      |   |
|----------------------|---|
| <code>infile</code>  | the name of a file with R code to be executed.  |
| <code>options</code> | a list of R command line options, e.g., for setting the amount of memory available and controlling the load/save process. If <code>infile</code> starts with a '-', use '--' as the final option. The default options are '--restore --save --no-readline'. (Without '--no-readline' on Windows.) |
| <code>outfile</code> | the name of a file to which to write output. If not given, the name used is that of <code>infile</code> , with a possible '.R' extension stripped, and '.Rout' appended.  |

**Details**

Use `R CMD BATCH --help` to be reminded of the usage.

By default, the input commands are printed along with the output. To suppress this behavior, add `options(echo = FALSE)` at the beginning of `infile`, or use option '--no-echo'.

The `infile` can have end of line marked by LF or CRLF (but not just CR), and files with an incomplete last line (missing end of line (EOL) mark) are processed correctly.

A final expression '`proc.time()`' will be executed after the input script unless the latter calls `q(runLast = FALSE)` or is aborted. This can be suppressed by the option '--no-timing'.

Additional options can be set by the environment variable `R_BATCH_OPTIONS`: these come after the default options (see the description of the `options` argument) and before any options given on the command line.

**Note**

On Unix-alikes only: Unlike `Splus BATCH`, this does not run the R process in the background. In most shells,

```
R CMD BATCH [options] infile [outfile] &
```

will do so.

---

bibentry

*Bibliography Entries*

---

**Description**

Functionality for representing and manipulating bibliographic information in enhanced BibTeX style.

**Usage**

```
bibentry(bibtype, textVersion = NULL, header = NULL, footer = NULL,
         key = NULL, ..., other = list(),
         mheader = NULL, mfooter = NULL)

## S3 method for class 'bibentry'
print(x, style = "text", .bibstyle,
      bibtex = length(x) <= getOption("citation.bibtex.max", 1),
      ...)
```

```
## S3 method for class 'bibentry'
format(x, style = "text", .bibstyle = NULL,
      bibtex = length(x) <= 1,
      citMsg = missing(bibtex),
      sort = FALSE, macros = NULL, ...)

## S3 method for class 'bibentry'
sort(x, decreasing = FALSE, .bibstyle = NULL, drop = FALSE, ...)

## S3 method for class 'citation'
print(x, style = "citation", ...)
## S3 method for class 'citation'
format(x, style = "citation", ...)

## S3 method for class 'bibentry'
toBibtex(object, escape = FALSE, ...)
```

## Arguments

|                          |  |
|--------------------------|--|
| <code>bibtype</code>     | a character string with a BibTeX entry type. See <b>Entry Types</b> for details.   |
| <code>textVersion</code> | a character string with a text representation of the reference to optionally be employed for printing. It is recommended to leave this unspecified if <code>format(x, style = "text")</code> works correctly. Only if special LaTeX macros (e.g., math formatting) or special characters (e.g., with accents) are necessary, a <code>textVersion</code> should be provided.  |
| <code>header</code>      | a character string with optional header text.  |
| <code>footer</code>      | a character string with optional footer text.  |
| <code>key</code>         | a character string giving the citation key for the entry.  |
| <code>...</code>         | for <code>bibentry</code> : arguments of the form <i>tag=value</i> giving the fields of the entry, with <i>tag</i> and <i>value</i> the name and value of the field, respectively. Arguments with empty values are dropped. Field names are case-insensitive. See <b>Entry Fields</b> for details.<br><br>For the <code>print()</code> method, extra arguments to pass to the renderer which typically includes the <code>format()</code> method.<br><br>For the <code>citation</code> class methods, arguments passed to the next method, i.e., the corresponding <code>bibentry</code> one.<br><br>For the <code>toBibtex()</code> method, currently not used. |
| <code>other</code>       | a list of arguments as in <code>...</code> (useful in particular for fields named the same as <code>formals</code> of <code>bibentry</code> ).   |
| <code>mheader</code>     | a character string with optional “outer” header text.  |
| <code>mfooter</code>     | a character string with optional “outer” footer text.  |
| <code>x</code>           | an object inheriting from class <code>"bibentry"</code> .  |
| <code>style</code>       | an optional character string specifying the print style. If present, must be a unique abbreviation (with case ignored) of the available styles, see <b>Details</b> .   |
| <code>decreasing</code>  | logical, passed to <code>order</code> indicating the sort direction.   |
| <code>.bibstyle</code>   | a character string naming a bibliography style, see <code>bibstyle</code> .  |

|        |  |
|--------|--|
| bibtex | logical indicating if BibTeX code should be given additionally; currently applies only to <code>style = "citation"</code> . The default for the <code>print()</code> method depends on the number of (bib) entries and <code>getOption("citation.bibtex.max")</code> (which itself is 1 by default). For example, to see no BibTeX at all, you can change the default by <code>options(citation.bibtex.max = 0)</code> . |
| citMsg | logical indicating if a “message” should be added (to the footer) about how to get BibTeX code when <code>bibtex</code> is false <i>and</i> <code>style = "citation"</code> .  |
| sort   | logical indicating if bibentries should be sorted, using <code>bibstyle(.bibstyle)\$sortKeys(x)</code> .   |
| macros | a character string or an object with already loaded Rd macros, see <b>Details</b> .  |
| drop   | logical used as <code>x[ ..., drop=drop]</code> inside the <code>sort()</code> method.   |
| object | an object inheriting from class "bibentry".  |
| escape | a logical indicating whether non-ASCII characters should be translated to LaTeX escape sequences.  |

## Details

The `bibentry` objects created by `bibentry` can represent an arbitrary positive number of references. One can use `c()` to combine `bibentry` objects, and hence in particular build a multiple reference object from single reference ones. Alternatively, one can use `bibentry` to directly create a multiple reference object by specifying the arguments as lists of character strings.

The `print` method for `bibentry` objects is based on a corresponding `format` method and provides a choice between seven different styles: plain text (`style = "text"`), BibTeX (`"bibtex"`), a mixture of plain text and BibTeX as traditionally used for citations (`"citation"`), HTML (`"html"`), L<sup>A</sup>T<sub>E</sub>X (`"latex"`), R code (`"R"`), and a simple copy of the `textVersion` elements (`style = "textVersion"`).

The `"text"`, `"html"` and `"latex"` styles make use of the `.bibstyle` argument: a style defined by the `bibstyle` function for rendering the `bibentry` into (intermediate) Rd format. The Rd format uses markup commands documented in the ‘Rd format’ section of the ‘Writing R Extensions’ manual, e.g. `\bold`. In addition, one can use the `macros` argument to provide additional (otherwise unknown, presumably LaTeX-style) Rd macros, either by giving the path to a file with Rd macros to be loaded via `loadRdMacros`, or an object with macros already loaded. Note that the `"latex"` result may contain commands from the L<sup>A</sup>T<sub>E</sub>X style file ‘`Rd.sty`’ shipped with R; put `\usepackage{Rd}` in the preamble of a LaTeX document to make these available when compiling, e.g. with `texi2pdf`.

When printing `bibentry` objects in citation style, a `header/footer` for each item can be displayed as well as a `mheader/mfooter` for the whole vector of references.

For formatting as R code, a choice between giving a character vector with one `bibentry()` call for each `bibentry` (as commonly used in ‘CITATION’ files), or a character string with one collapsed call, obtained by combining the individual calls with `c()` if there is more than one `bibentry`. This can be controlled by passing the argument `collapse=FALSE` (default) or `TRUE`, respectively, to the `format()` method. (*Printing in R style always collapses to a single call.*)

It is possible to subscript `bibentry` objects by their keys (which are used for character subscripts if the names are `NULL`).

There is also a `toBibtex` method for direct conversion to BibTeX.

As of R 4.3.0, there is also a `transform` method which allows to directly use the current fields, see the examples.

## Value

`bibentry` produces an object of class `"bibentry"`.

## Entry Types

`bibentry` creates `"bibentry"` objects, which are modeled after BibTeX entries. The entry should be a valid BibTeX entry type, e.g.,

**Article:** An article from a journal or magazine.

**Book:** A book with an explicit publisher.

**InBook:** A part of a book, which may be a chapter (or section or whatever) and/or a range of pages.

**InCollection:** A part of a book having its own title.

**InProceedings:** An article in a conference proceedings.

**Manual:** Technical documentation like a software manual.

**MastersThesis:** A Master's thesis.

**Misc:** Use this type when nothing else fits.

**PhdThesis:** A PhD thesis.

**Proceedings:** The proceedings of a conference.

**TechReport:** A report published by a school or other institution, usually numbered within a series.

**Unpublished:** A document having an author and title, but not formally published.

## Entry Fields

The ... argument of `bibentry` can be any number of BibTeX fields, including

**address:** The address of the publisher or other type of institution.

**author:** The name(s) of the author(s), either as a `person` object, or as a character string which `as.person` correctly coerces to such.

**booktitle:** Title of a book, part of which is being cited.

**chapter:** A chapter (or section or whatever) number.

**doi:** The DOI ([https://en.wikipedia.org/wiki/Digital\\_Object\\_Identifier](https://en.wikipedia.org/wiki/Digital_Object_Identifier)) for the reference.

**editor:** Name(s) of editor(s), same format as `author`.

**institution:** The publishing institution of a technical report.

**journal:** A journal name.

**note:** Any additional information that can help the reader. The first word should be capitalized.

**number:** The number of a journal, magazine, technical report, or of a work in a series.

**pages:** One or more page numbers or range of numbers.

**publisher:** The publisher's name.

**school:** The name of the school where a thesis was written.

**series:** The name of a series or set of books.

**title:** The work's title.

**url:** A URL for the reference. (If the URL is an expanded DOI, we recommend to use the `'doi'` field with the unexpanded DOI instead.)

**volume:** The volume of a journal or multi-volume book.

**year:** The year of publication.

## One collapsed call:
writeLines(format(bref, "R", collapse = TRUE))

```

---

browseEnv

*Browse Objects in Environment*

---

## Description

The `browseEnv` function opens a browser with list of objects currently in `sys.frame()` environment.

## Usage

```

browseEnv(envir = .GlobalEnv, pattern,
          excludepatt = "^last\\.warning",
          html = .Platform$GUI != "AQUA",
          expanded = TRUE, properties = NULL,
          main = NULL, debugMe = FALSE)

```

## Arguments

|                          |   |
|--------------------------|---|
| <code>envir</code>       | an <a href="#">environment</a> the objects of which are to be browsed.  |
| <code>pattern</code>     | a <a href="#">regular expression</a> for object subselection is passed to the internal <code>ls()</code> call.  |
| <code>excludepatt</code> | a regular expression for <i>dropping</i> objects with matching names.   |
| <code>html</code>        | is used to display the workspace on a HTML page in your favorite browser. The default except when running from R. app on macOS.   |
| <code>expanded</code>    | whether to show one level of recursion. It can be useful to switch it to FALSE if your workspace is large. This option is ignored if <code>html</code> is set to FALSE. |

|            |   |
|------------|---|
| properties | a named list of global properties (of the objects chosen) to be showed in the browser; when NULL (as per default), user, date, and machine information is used. |
| main       | a title string to be used in the browser; when NULL (as per default) a title is constructed.  |
| debugMe    | logical switch; if true, some diagnostic output is produced.  |

### Details

Very experimental code: displays a static HTML page on all platforms except R . app on macOS.

Only allows one level of recursion into object structures.

It can be generalized. See sources for details. Most probably, this should rather work through using the **tkWidget** package (from <https://www.bioconductor.org>).

### Examples

```
if(interactive()) {
  ## create some interesting objects :
  ofa <- ordered(4:1)
  ex1 <- expression(1+ 0:9)
  ex3 <- expression(u, v, 1+ 0:9)
  example(factor, echo = FALSE)
  example(table, echo = FALSE)
  example(ftable, echo = FALSE)
  example(lm, echo = FALSE, ask = FALSE)
  example(str, echo = FALSE)

  ## and browse them:
  browseEnv()

  ## a (simple) function's environment:
  afl2 <- approxfun(1:2, 1:2, method = "const")
  browseEnv(envir = environment(afl2))
}
```

---

browseURL

*Load URL into an HTML Browser*

---

### Description

Load a given URL into an HTML browser.

### Usage

```
browseURL(url, browser = getOption("browser"),
          encodeIfNeeded = FALSE)
```

**Arguments**

|                             |  |
|-----------------------------|--|
| <code>url</code>            | a non-empty character string giving the URL to be loaded. Some platforms also accept file paths.   |
| <code>browser</code>        | a non-empty character string giving the name of the program to be used as the HTML browser. It should be in the PATH, or a full path specified. Alternatively, an R function to be called to invoke the browser.<br>Under Windows <code>NULL</code> is also allowed (and is the default), and implies that the file association mechanism will be used.                            |
| <code>encodeIfNeeded</code> | Should the URL be encoded by <code>URLencode</code> before passing to the browser? This is not needed (and might be harmful) if the <code>browser</code> program/function itself does encoding, and can be harmful for <code>'file:/'</code> URLs on some systems and for <code>'http:/'</code> URLs passed to some CGI applications. Fortunately, most URLs do not need encoding. |

**Details**

**On Unix-alikes:** The default browser is set by option `"browser"`, in turn set by the environment variable `R_BROWSER` which is by default set in file `'R_HOME/etc/Renviron'` to a choice made manually or automatically when R was configured. (See [Startup](#) for where to override that default value.) To suppress showing URLs altogether, use the value `"false"`.

On many platforms it is best to set option `"browser"` to a generic program/script and let that invoke the user's choice of browser. For example, on macOS use `open` and on many other Unix-alikes use `xdg-open`.

If `browser` supports remote control and R knows how to perform it, the URL is opened in any already-running browser or a new one if necessary. This mechanism currently is available for browsers which support the `"-remote openURL(...)"` interface (which includes Mozilla and Opera), Galeon, KDE konqueror (*via* `kfmclient`) and the GNOME interface to Mozilla. (Firefox has dropped support, but defaults to using an already-running browser.) Note that the type of browser is determined from its name, so this mechanism will only be used if the browser is installed under its canonical name.

Because `"-remote"` will use any browser displaying on the X server (whatever machine it is running on), the remote control mechanism is only used if `DISPLAY` points to the local host. This may not allow displaying more than one URL at a time from a remote host.

It is the caller's responsibility to encode `url` if necessary (see [URLencode](#)).

To suppress showing URLs altogether, set `browser = "false"`.

The behaviour for arguments `url` which are not URLs is platform-dependent. Some platforms accept absolute file paths; fewer accept relative file paths.

**On Windows:** The default browser is set by option `"browser"`, in turn set by the environment variable `R_BROWSER` if that is set, otherwise to `NULL`. To suppress showing URLs altogether, use the value `"false"`.

Some browsers have required `':'` be replaced by `'|'` in file paths: others do not accept that. All seem to accept `'\'` as a path separator even though the RFC1738 standard requires `'/'`.

To suppress showing URLs altogether, set `browser = "false"`.

**URL schemes**

Which URL schemes are accepted is platform-specific: expect `'http:/'`, `'https:/'` and `'ftp:/'` to work, but `'mailto:'` may or may not (and if it does may not use the user's preferred email client). However, modern browsers are unlikely to handle `'ftp:/'`.

For the `'file:/'` scheme the format accepted (if any) can depend on both browser and OS.

**Examples**

```
## Not run:
## for KDE users who want to open files in a new tab
options(browser = "kfmclient newTab")

browseURL("https://www.r-project.org")

## On Windows-only, something like
browseURL("file:///d:/R/R-2.5.1/doc/html/index.html",
          browser = "C:/Program Files/Mozilla Firefox/firefox.exe")

## End(Not run)
```

---

|                 |  |
|-----------------|--|
| browseVignettes | <i>List Vignettes in an HTML Browser</i> |
|-----------------|--|

---

**Description**

List available vignettes in an HTML browser with links to PDF, LaTeX/Noweb source, and (tangled) R code (if available).

**Usage**

```
browseVignettes(package = NULL, lib.loc = NULL, all = TRUE)

## S3 method for class 'browseVignettes'
print(x, ...)
```

**Arguments**

|                      |   |
|----------------------|---|
| <code>package</code> | a character vector with the names of packages to search through, or <code>NULL</code> in which "all" packages (as defined by argument <code>all</code> ) are searched.          |
| <code>lib.loc</code> | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known.               |
| <code>all</code>     | logical; if <code>TRUE</code> search all available packages in the library trees specified by <code>lib.loc</code> , and if <code>FALSE</code> , search only attached packages. |
| <code>x</code>       | Object of class <code>browseVignettes</code> .  |
| <code>...</code>     | Further arguments, ignored by the <code>print</code> method.  |

**Details**

Function `browseVignettes` returns an object of the same class; the `print` method displays it as an HTML page in a browser (using [browseURL](#)).

**See Also**

[browseURL](#), [vignette](#)

**Examples**

```
## List vignettes from all *attached* packages
browseVignettes(all = FALSE)

## List vignettes from a specific package
browseVignettes("grid")
```

bug.report

*Send a Bug Report***Description**

Invokes an editor or email program to write a bug report or opens a web page for bug submission. Some standard information on the current version and configuration of R are included automatically.

**Usage**

```
bug.report(subject = "", address,
           file = "R.bug.report", package = NULL, lib.loc = NULL,
           ...)
```

**Arguments**

|         |  |
|---------|--|
| subject | Subject of the email.  |
| address | Recipient's email address, where applicable: for package bug reports sent by email this defaults to the address of the package maintainer (the first if more than one is listed).  |
| file    | filename to use (if needed) for setting up the email.  |
| package | Optional character vector naming a single package which is the subject of the bug report.  |
| lib.loc | A character vector describing the location of R library trees in which to search for the package, or NULL. The default value of NULL corresponds to all libraries currently known. |
| ...     | additional named arguments such as <code>method</code> and <code>ccaddress</code> to pass to <code>create.post</code> .  |

**Details**

If `package` is NULL or a base package, this opens the R bugs tracker at <https://bugs.r-project.org/>.

If `package` is specified, it is assumed that the bug report is about that package, and parts of its 'DESCRIPTION' file are added to the standard information. If the package has a non-empty `BugReports` field in the 'DESCRIPTION' file specifying the URL of a webpage, that URL will be opened using `browseURL`, otherwise an email directed to the package maintainer will be generated using `create.post`. If there is any other form of `BugReports` field or a `Contact` field, this is examined as it may provide a preferred email address.

**Value**

Nothing useful.

### When is there a bug?

If R executes an illegal instruction, or dies with an operating system error message that indicates a problem in the program (as opposed to something like “disk full”), then it is certainly a bug.

Taking forever to complete a command can be a bug, but you must make certain that it was really R’s fault. Some commands simply take a long time. If the input was such that you KNOW it should have been processed quickly, report a bug. If you don’t know whether the command should take a long time, find out by looking in the manual or by asking for assistance.

If a command you are familiar with causes an R error message in a case where its usual definition ought to be reasonable, it is probably a bug. If a command does the wrong thing, that is a bug. But be sure you know for certain what it ought to have done. If you aren’t familiar with the command, or don’t know for certain how the command is supposed to work, then it might actually be working right. Rather than jumping to conclusions, show the problem to someone who knows for certain.

Finally, a command’s intended definition may not be best for statistical analysis. This is a very important sort of problem, but it is also a matter of judgement. Also, it is easy to come to such a conclusion out of ignorance of some of the existing features. It is probably best not to complain about such a problem until you have checked the documentation in the usual ways, feel confident that you understand it, and know for certain that what you want is not available. The mailing list `r-devel@r-project.org` is a better place for discussions of this sort than the bug list.

If you are not sure what the command is supposed to do after a careful reading of the manual this indicates a bug in the manual. The manual’s job is to make everything clear. It is just as important to report documentation bugs as program bugs.

If the online argument list of a function disagrees with the manual, one of them must be wrong, so report the bug.

### How to report a bug

When you decide that there is a bug, it is important to report it and to report it in a way which is useful. What is most useful is an exact description of what commands you type, from when you start R until the problem happens. Always include the version of R, machine, and operating system that you are using; type `version` in R to print this. To help us keep track of which bugs have been fixed and which are still open please send a separate report for each bug.

The most important principle in reporting a bug is to report FACTS, not hypotheses or categorizations. It is always easier to report the facts, but people seem to prefer to strain to posit explanations and report them instead. If the explanations are based on guesses about how R is implemented, they will be useless; we will have to try to figure out what the facts must have been to lead to such speculations. Sometimes this is impossible. But in any case, it is unnecessary work for us.

For example, suppose that on a data set which you know to be quite large the command `data.frame(x, y, z, monday, tuesday)` never returns. Do not report that `data.frame()` fails for large data sets. Perhaps it fails when a variable name is a day of the week. If this is so then when we got your report we would try out the `data.frame()` command on a large data set, probably with no day of the week variable name, and not see any problem. There is no way in the world that we could guess that we should try a day of the week variable name.

Or perhaps the command fails because the last command you used was a `[` method that had a bug causing R’s internal data structures to be corrupted and making the `data.frame()` command fail from then on. This is why we need to know what other commands you have typed (or read from your startup file).

It is very useful to try and find simple examples that produce apparently the same bug, and somewhat useful to find simple examples that might be expected to produce the bug but actually do not. If you want to debug the problem and find exactly what caused it, that is wonderful. You should still report the facts as well as any explanations or solutions.

Invoking R with the ‘--vanilla’ option may help in isolating a bug. This ensures that the site profile and saved data files are not read.

A bug report can be generated using the function `bug.report()`. For reports on R this will open the Web page at <https://bugs.r-project.org/>: for a contributed package it will open the package’s bug tracker Web page or help you compose an email to the maintainer.

Bug reports on **contributed packages** should not be sent to the R bug tracker: rather make use of the `package` argument.

### Author(s)

---

|                |  |
|----------------|--|
| capture.output | <i>Send Output to a Character String or File</i> |
|----------------|--|

---

### Description

Evaluates its arguments with the output being returned as a character string or sent to a file. Related to `sink` similarly to how `with` is related to `attach`.

### Usage

```
capture.output(..., file = NULL, append = FALSE,
               type = c("output", "message"), split = FALSE)
```

### Arguments

|                          |   |
|--------------------------|---|
| <code>...</code>         | Expressions to be evaluated.  |
| <code>file</code>        | A file name or a <a href="#">connection</a> , or <code>NULL</code> to return the output as a character vector. If the connection is not open, it will be opened initially and closed on exit. |
| <code>append</code>      | logical. If <code>file</code> a file name or unopened connection, append or overwrite?  |
| <code>type, split</code> | are passed to <code>sink()</code> , see there.  |

### Details

It works via `sink(<file connection>)` and hence the R code in `dots` must *not* interfere with the connection (e.g., by calling `closeAllConnections()`).

An attempt is made to write output as far as possible to `file` if there is an error in evaluating the expressions, but for `file = NULL` all output will be lost.

Messages sent to `stderr()` (including those from `message`, `warning` and `stop`) are captured by `type = "message"`. Note that this can be “unsafe” and should only be used with care.

**Value**

A character string (if `file = NULL`), or invisible `NULL`.

**See Also**

[sink](#), [textConnection](#)

**Examples**

```
require(stats)
glmout <- capture.output(summary(glm(case ~ spontaneous+induced,
                                   data = infer, family = binomial()))

glmout[1:5]
capture.output(1+1, 2+2)
capture.output({1+1; 2+2})

## Not run: ## on Unix-alike with a2ps available
op <- options(useFancyQuotes=FALSE)
pdf <- pipe("a2ps -o - | ps2pdf - tempout.pdf", "w")
capture.output(example(glm), file = pdf)
close(pdf); options(op) ; system("evince tempout.pdf &")

## End(Not run)
```

---

changedFiles

*Detect which Files Have Changed*

---

**Description**

`fileSnapshot` takes a snapshot of a selection of files, recording summary information about each. `changedFiles` compares two snapshots, or compares one snapshot to the current state of the file system. The snapshots need not be the same directory; this could be used to compare two directories.

**Usage**

```
fileSnapshot(path = ".", file.info = TRUE, timestamp = NULL,
             md5sum = FALSE, digest = NULL, full.names = length(path) > 1,
             ...)

changedFiles(before, after, path = before$path, timestamp = before$timestamp,
             check.file.info = c("size", "isdir", "mode", "mtime"),
             md5sum = before$md5sum, digest = before$digest,
             full.names = before$full.names, ...)

## S3 method for class 'fileSnapshot'
print(x, verbose = FALSE, ...)

## S3 method for class 'changedFiles'
print(x, verbose = FALSE, ...)
```

**Arguments**

|                              |   |
|------------------------------|---|
| <code>path</code>            | character vector; the path(s) to record.  |
| <code>file.info</code>       | logical; whether to record <code>file.info</code> values for each file.   |
| <code>timestamp</code>       | character string or NULL; the name of a file to write at the time the snapshot is taken. This gives a quick test for modification, but may be unreliable; see the Details.  |
| <code>md5sum</code>          | logical; whether MD5 summaries of each file should be taken as part of the snapshot.  |
| <code>digest</code>          | a function or NULL; a function with header <code>function(filename)</code> which will take a vector of filenames and produce a vector of values of the same length, or a matrix with that number of rows.   |
| <code>full.names</code>      | logical; whether full names (as in <code>list.files</code> ) should be recorded. Must be TRUE if <code>length(path) &gt; 1</code> .   |
| <code>...</code>             | additional parameters to pass to <code>list.files</code> to control the set of files in the snapshots.  |
| <code>before, after</code>   | objects produced by <code>fileSnapshot</code> ; two snapshots to compare. If <code>after</code> is missing, a new snapshot of the current file system will be produced for comparison, using arguments recorded in <code>before</code> as defaults. |
| <code>check.file.info</code> | character vector; which columns from <code>file.info</code> should be compared.   |
| <code>x</code>               | the object to print.  |
| <code>verbose</code>         | logical; whether to list all data when printing.  |

**Details**

The `fileSnapshot` function uses `list.files` to obtain a list of files, and depending on the `file.info`, `md5sum`, and `digest` arguments, records information about each file.

The `changedFiles` function compares two snapshots.

If the `timestamp` argument to `fileSnapshot` is length 1, a file with that name is created. If it is length 1 in `changedFiles`, the `file_test` function is used to compare the age of all files common to both `before` and `after` to it. This test may be unreliable: it compares the current modification time of the `after` files to the timestamp; that may not be the same as the modification time when the `after` snapshot was taken. It may also give incorrect results if the clock on the file system holding the timestamp differs from the one holding the snapshot files.

If the `check.file.info` argument contains a non-empty character vector, the indicated columns from the result of a call to `file.info` will be compared.

If `md5sum` is TRUE, `fileSnapshot` will call the `tools::md5sum` function to record the 32 byte MD5 checksum for each file, and `changedFiles` will compare the values. The `digest` argument allows users to provide their own digest function.

**Value**

`fileSnapshot` returns an object of class `"fileSnapshot"`. This is a list containing the fields

|                   |  |
|-------------------|--|
| <code>info</code> | a data frame whose rownames are the filenames, and whose columns contain the requested snapshot data |
| <code>path</code> | the normalized path from the call  |

timestamp, file.info, md5sum, digest, full.names  
                                   a record of the other arguments from the call

args                              other arguments passed via . . . to `list.files`.

changedFiles produces an object of class "changedFiles". This is a list containing

added, deleted, changed, unchanged  
                                   character vectors of filenames from the before and after snapshots, with obvious meanings

changes                          a logical matrix with a row for each common file, and a column for each comparison test. TRUE indicates a change in that test.

`print` methods are defined for each of these types. The `print` method for "fileSnapshot" objects displays the arguments used to produce them, while the one for "changedFiles" displays the added, deleted and changed fields if non-empty, and a submatrix of the changes matrix containing all of the TRUE values.

### Author(s)

Duncan Murdoch, using suggestions from Karl Millar and others.

### See Also

`file.info`, `file_test`, `md5sum`.

### Examples

```
# Create some files in a temporary directory
dir <- tempfile()
dir.create(dir)
writeBin(1L, file.path(dir, "file1"))
writeBin(2L, file.path(dir, "file2"))
dir.create(file.path(dir, "dir"))

# Take a snapshot
snapshot <- fileSnapshot(dir, timestamp = tempfile("timestamp"), md5sum=TRUE)

# Change one of the files.
writeBin(3L:4L, file.path(dir, "file2"))

# Display the detected changes. We may or may not see mtime change...
changedFiles(snapshot)
changedFiles(snapshot)$changes
```

---

charClass

*Character Classification*

---

### Description

An interface to the (C99) wide character classification functions in use.

### Usage

```
charClass(x, class)
```

## Arguments

|                    |   |
|--------------------|---|
| <code>x</code>     | <b>Either</b> a UTF-8-encoded length-1 character vector <b>or</b> an integer vector of Unicode points (or a vector coercible to integer). |
| <code>class</code> | A character string, one of those given in the ‘Details’ section.  |

## Details

The classification into character classes is platform-dependent. The classes are determined by internal tables on Windows and (optionally but by default) on macOS and AIX.

The character classes are interpreted as follows:

|          |   |
|----------|---|
| "alnum"  | Alphabetic or numeric.  |
| "alpha"  | Alphabetic.   |
| "blank"  | Space or tab.   |
| "cntrl"  | Control characters.   |
| "digit"  | Digits 0–9.   |
| "graph"  | Graphical characters (printable characters except whitespace).  |
| "lower"  | Lower-case alphabetic.  |
| "print"  | Printable characters.   |
| "punct"  | Punctuation characters. Some platforms treat all non-alphanumeric graphical characters as punctuation.                          |
| "space"  | Whitespace, including tabs, form and line feeds and carriage returns. Some OSes include non-breaking spaces, some exclude them. |
| "upper"  | Upper-case alphabetic.  |
| "xdigit" | Hexadecimal character, one of 0–9A–fa–f.  |

Alphabetic characters contain all lower- and upper-case ones and some others (for example, those in ‘title case’).

Whether a character is printable is used to decide whether to escape it when printing – see the help for [print.default](#).

If `x` is a character string it should either be ASCII or declared as UTF-8 – see [Encoding](#).

`charClass` was added in R 4.1.0. A less direct way to examine character classes which also worked in earlier versions is to use something like `grepl("[:print:]", intToUtf8(x))` – however, the regular-expression code might not use the same classification functions as printing and on macOS used not to.

## Value

A logical vector of the length the number of characters or integers in `x`.

## Note

Non-ASCII digits are excluded by the C99 standard from the class "digit": most platforms will have them as alphabetic.

It is an assumption that the system’s wide character classification functions are coded in Unicode points, but this is known to be true for all recent platforms.

The classification may depend on the locale even on one platform.

**See Also**

Character classes are used in [regular expressions](#).

The OS's man pages for `iswctype` and `wctype`.

**Examples**

```
x <- c(48:70, 32, 0xa0) # Last is non-breaking space
cl <- c("alnum", "alpha", "blank", "digit", "graph", "punct", "upper", "xdigit")
X <- lapply(cl, function(y) charClass(x,y)); names(X) <- cl
X <- as.data.frame(X); row.names(X) <- sQuote(intToUtf8(x, multiple = TRUE))
X

charClass("ABC123", "alpha")
## Some accented capital Greek characters
(x <- "\u0386\u0388\u0389")
charClass(x, "upper")

## How many printable characters are there? (Around 280,000 in Unicode 13.)
## There are 2^21-1 possible Unicode points (most not yet assigned).
pr <- charClass(1:0x1fffff, "print")
table(pr)
```

---

choose.dir

---

*Choose a Folder Interactively on MS Windows*

---

**Description**

Use a Windows shell folder widget to choose a folder interactively.

**Usage**

```
choose.dir(default = "", caption = "Select folder")
```

**Arguments**

|                      |                                      |
|----------------------|--------------------------------------|
| <code>default</code> | which folder to show initially.      |
| <code>caption</code> | the caption on the selection dialog. |

**Details**

This brings up the Windows shell folder selection widget. With the default `default = ""`, ‘My Computer’ (or similar) is initially selected.

To workaround a bug, on Vista and later only folders under ‘Computer’ are accessible via the widget.

**Value**

A length-one character vector, character NA if ‘Cancel’ was selected.

**Note**

This is only available on Windows.

**See Also**

`choose.files` (on Windows) and `file.choose` (on all platforms).

**Examples**

```
if (interactive() && .Platform$OS.type == "windows")
  choose.dir(getwd(), "Choose a suitable folder")
```

---

`choose.files`

*Choose a List of Files Interactively on MS Windows*

---

**Description**

Use a Windows file dialog to choose a list of zero or more files interactively.

**Usage**

```
choose.files(default = "", caption = "Select files",
             multi = TRUE, filters = Filters,
             index = nrow(Filters))
```

`Filters`

**Arguments**

|                      |  |
|----------------------|--|
| <code>default</code> | which filename to show initially               |
| <code>caption</code> | the caption on the file selection dialog       |
| <code>multi</code>   | whether to allow multiple files to be selected |
| <code>filters</code> | a matrix of filename filters (see Details)     |
| <code>index</code>   | which row of filters to use by default         |

**Details**

Unlike `file.choose`, `choose.files` will always attempt to return a character vector giving a list of files. If the user cancels the dialog, then zero files are returned, whereas `file.choose` would signal an error. `choose.dir` chooses a directory.

Windows file dialog boxes include a list of ‘filters’, which allow the file selection to be limited to files of specific types. The `filters` argument to `choose.files` allows the list of filters to be set. It should be an `n` by 2 character matrix. The first column gives, for each filter, the description the user will see, while the second column gives the mask(s) to select those files. If more than one mask is used, separate them by semicolons, with no spaces. The `index` argument chooses which filter will be used initially.

`Filters` is a matrix giving the descriptions and masks for the file types that R knows about. Print it to see typical formats for filter specifications. The examples below show how particular filters may be selected.

If you would like to display files in a particular directory, give a fully qualified file mask (e.g., `"c:\\*.*)" in the default argument. If a directory is not given, the dialog will start in the current directory the first time, and remember the last directory used on subsequent invocations.`

There is a buffer limit on the total length of the selected filenames: it is large but this function is not intended to select thousands of files, when the limit might be reached.

**Value**

A character vector giving zero or more file paths.

**Note**

This is only available on Windows.

**See Also**

`file.choose`, `choose.dir`.

`Sys.glob` or `list.files` to select multiple files by pattern.

**Examples**

```
if (interactive() && .Platform$OS.type == "windows")
  choose.files(filters = Filters[c("zip", "All"),])
```

---

|                  |                                     |
|------------------|-------------------------------------|
| chooseBioCmirror | <i>Select a Bioconductor Mirror</i> |
|------------------|-------------------------------------|

---

**Description**

Interact with the user to choose a Bioconductor mirror.

**Usage**

```
chooseBioCmirror(graphics = getOption("menu.graphics"), ind = NULL,
  local.only = FALSE)
```

**Arguments**

|                         |  |
|-------------------------|--|
| <code>graphics</code>   | Logical. If true, use a graphical list: on Windows or the macOS GUI use a list box, and on a Unix-alike use a Tk widget if package <b>tktk</b> and an X server are available. Otherwise use a text <code>menu</code> . |
| <code>ind</code>        | Optional numeric value giving which entry to select.   |
| <code>local.only</code> | Logical, try to get most recent list from the Bioconductor master or use file on local disk only.  |

**Details**

This sets the `option` "BioC\_mirror": it is used before a call to `setRepositories`. The out-of-the-box default for that option is `NULL`, which currently corresponds to the mirror <https://bioconductor.org>.

The 'Bioconductor (World-wide)' 'mirror' is a network of mirrors providing reliable world-wide access; other mirrors may provide faster access on a geographically local scale.

`ind` chooses a row in '[R\\_HOME](#)/doc/BioC\_mirrors.csv', by number.

**Value**

None: this function is invoked for its side effect of updating `options("BioC_mirror")`.

**See Also**

[setRepositories](#), [chooseCRANmirror](#).

---

chooseCRANmirror      *Select a CRAN Mirror*

---

**Description**

Interact with the user to choose a CRAN mirror.

**Usage**

```
chooseCRANmirror(graphics = getOption("menu.graphics"), ind = NULL,
                  local.only = FALSE)
```

```
getCRANmirrors(all = FALSE, local.only = FALSE)
```

**Arguments**

|                         |   |
|-------------------------|---|
| <code>graphics</code>   | Logical. If true, use a graphical list: on Windows or the macOS GUI use a list box, and on a Unix-alike use a Tk widget if package <b>tk</b> and an X server are available. Otherwise use a text <a href="#">menu</a> . |
| <code>ind</code>        | Optional numeric value giving which entry to select.  |
| <code>all</code>        | Logical, get all known mirrors or only the ones flagged as OK.  |
| <code>local.only</code> | Logical, try to get most recent list from the CRAN master or use file on local disk only.   |

**Details**

A list of mirrors is stored in file '[R\\_HOME](#)/doc/CRAN\_mirrors.csv', but first an on-line list of current mirrors is consulted, and the file copy used only if the on-line list is inaccessible.

`chooseCRANmirror` is called by a Windows GUI menu item and by [contrib.url](#) if it finds the initial dummy value of `options("repos")`.

HTTPS mirrors with mirroring over `ssh` will be offered in preference to other mirrors (which are listed in a sub-menu).

`ind` chooses a row in the list of current mirrors, by number. It is best used with `local.only = TRUE` and row numbers in '[R\\_HOME](#)/doc/CRAN\_mirrors.csv'.

**Value**

None for `chooseCRANmirror()`, this function is invoked for its side effect of updating `options("repos")`.

`getCRANmirrors()` returns a data frame with mirror information.

**See Also**

[setRepositories](#), [findCRANmirror](#), [chooseBioCmirror](#), [contrib.url](#).

citation

*Citing R and R Packages in Publications***Description**

How to cite R and R packages in publications.

**Usage**

```
citation(package = "base", lib.loc = NULL, auto = NULL)

readCitationFile(file, meta = NULL)
citHeader(...)
citFooter(...)
```

**Arguments**

|                      |   |
|----------------------|---|
| <code>package</code> | a character string with the name of a single package. An error occurs if more than one package name is given.   |
| <code>lib.loc</code> | a character vector with path names of R libraries, or the directory containing the source for <code>package</code> , or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.         |
| <code>auto</code>    | a logical indicating whether the default citation auto-generated from the package ‘DESCRIPTION’ metadata should be used or not, or <code>NULL</code> (default), indicating that a ‘CITATION’ file is used if it exists, or an object of class “ <a href="#">packageDescription</a> ” with package metadata (see below). |
| <code>file</code>    | a file name.  |
| <code>meta</code>    | a list of package metadata as obtained by <a href="#">packageDescription</a> , or <code>NULL</code> (the default).  |
| <code>...</code>     | character strings (which will be <a href="#">pasted</a> ).  |

**Details**

The R core development team and the very active community of package authors have invested a lot of time and effort in creating R as it is today. Please give credit where credit is due and cite R and R packages when you use them for data analysis.

Execute function `citation()` for information on how to cite the base R system in publications. If the name of a non-base package is given, the function either returns the information contained in the ‘CITATION’ file of the package (using `readCitationFile` with `meta` equal to `packageDescription(package, lib.loc)`) or auto-generates citation information from the ‘DESCRIPTION’ file.

Packages can use an ‘Authors@R’ field in their ‘DESCRIPTION’ to provide (R code giving) a [person](#) object with a refined, machine-readable description of the package “authors” (in particular specifying their precise roles). Only those with an author role will be included in the auto-generated citation.

If the object returned by `citation()` contains only one reference, the associated print method shows both a text version and a BibTeX entry for it. If a package has more than one reference then only the text versions are shown. This threshold is controlled by

`options("citation.bibtex.max")`. The BibTeX versions can also be obtained using function `toBibtex()` (see the examples below).

The ‘CITATION’ file of an R package should be placed in the ‘inst’ subdirectory of the package source. The file is an R source file and may contain arbitrary R commands including conditionals and computations. Function `readCitationFile()` is used by `citation()` to extract the information in ‘CITATION’ files. The file is `source()`ed by the R parser in a temporary environment and all resulting bibliographic objects (specifically, inheriting from “`bibentry`”) are collected. These are typically produced by one or more `bibentry()` calls, optionally preceded by a `citHeader()` and followed by a `citFooter()` call. One can include an auto-generated package citation in the ‘CITATION’ file via `citation(auto = meta)`.

`readCitationFile` makes use of the `Encoding` element (if any) of `meta` to determine the encoding of the file.

## Value

An object of class “`citation`”, inheriting from class “`bibentry`”; see there, notably for the `print` and `format` methods.

`citHeader` and `citFooter` return an empty “`bibentry`” storing “outer” header/footer text for the package citation.

## See Also

`bibentry`

## Examples

```
## the basic R reference
citation()

## extract the BibTeX entry from the return value
x <- citation()
toBibtex(x)

## references for a package
citation("lattice")
citation("lattice", auto = TRUE) # request the Manual-type reference
citation("foreign")

## a CITATION file with more than one bibentry:
file.show(system.file("CITATION", package="mgcv"))
cm <- citation("mgcv")
cm # header, text references, plus "reminder" about getting BibTeX
print(cm, bibtex = TRUE) # each showing its bibtex code

## a CITATION file including citation(auto = meta)
file.show(system.file("CITATION", package="nlme"))
citation("nlme")
```

cite

*Cite a Bibliography Entry***Description**

Cite a `bibentry` object in text. The `cite()` function uses the `cite()` function from the default `bibstyle` if present, or `citeNatbib()` if not. `citeNatbib()` uses a style similar to that used by the LaTeX package **natbib**.

**Usage**

```

cite(keys, bib, ...)
citeNatbib(keys, bib, textual = FALSE, before = NULL, after = NULL,
            mode = c("authoryear", "numbers", "super"),
            abbreviate = TRUE, longnamesfirst = TRUE,
            bibpunct = c("(", ")", ";", "a", "", ",", previous))

```

**Arguments**

|                             |   |
|-----------------------------|---|
| <code>keys</code>           | A character vector of keys of entries to cite. May contain multiple keys in a single entry, separated by commas.                        |
| <code>bib</code>            | A " <code>bibentry</code> " object containing the list of documents in which to find the keys.  |
| <code>...</code>            | Additional arguments to pass to the <code>cite()</code> function for the default style.   |
| <code>textual</code>        | Produce a "textual" style of citation, i.e. what <code>\citet</code> would produce in LaTeX.  |
| <code>before</code>         | Optional text to display before the citation.   |
| <code>after</code>          | Optional text to display after the citation.  |
| <code>mode</code>           | The "mode" of citation.   |
| <code>abbreviate</code>     | Whether to abbreviate long author lists.  |
| <code>longnamesfirst</code> | If <code>abbreviate == TRUE</code> , whether to leave the first citation long.  |
| <code>bibpunct</code>       | A vector of punctuation to use in the citation, as used in <b>natbib</b> . See the Details section.                                     |
| <code>previous</code>       | A list of keys that have been previously cited, to be used when <code>abbreviate == TRUE</code> and <code>longnamesfirst == TRUE</code> |

**Details**

Argument names are chosen based on the documentation for the LaTeX **natbib** package. See that documentation for the interpretation of the `bibpunct` entries.

The entries in `bibpunct` are as follows:

1. The left delimiter.
2. The right delimiter.
3. The separator between references within a citation.
4. An indicator of the "mode": "n" for numbers, "s" for superscripts, anything else for author-year.

5. Punctuation to go between the author and year.
6. Punctuation to go between years when authorship is suppressed.

Note that if `mode` is specified, it overrides the mode specification in `bibpunct[4]`. Partial matching is used for `mode`.

The defaults for `citeNatbib` have been chosen to match the JSS style, and by default these are used in `cite`. See [bibstyle](#) for how to set a different default style.

## Value

A single element character string is returned, containing the citation.

## Author(s)

Duncan Murdoch

## Examples

```
## R reference
rref <- bibentry(
  bibtype = "Manual",
  title = "R: A Language and Environment for Statistical Computing",
  author = person("R Core Team"),
  organization = "R Foundation for Statistical Computing",
  address = "Vienna, Austria",
  year = 2013,
  url = "https://www.R-project.org/",
  key = "R")

## References for boot package and associated book
bref <- c(
  bibentry(
    bibtype = "Manual",
    title = "boot: Bootstrap R (S-PLUS) Functions",
    author = c(
      person("Angelo", "Canty", role = "aut",
        comment = "S original"),
      person(c("Brian", "D."), "Ripley", role = c("aut", "trl", "cre"),
        comment = "R port, author of parallel support",
        email = "ripley@stats.ox.ac.uk")
    ),
    year = "2012",
    note = "R package version 1.3-4",
    url = "https://CRAN.R-project.org/package=boot",
    key = "boot-package"
  ),
  bibentry(
    bibtype = "Book",
    title = "Bootstrap Methods and Their Applications",
    author = as.person("Anthony C. Davison [aut], David V. Hinkley [aut]"),
    year = "1997",
    publisher = "Cambridge University Press",
    address = "Cambridge",
    isbn = "0-521-57391-2",
    url = "http://statwww.epfl.ch/davison/BMA/"
```

```

        key = "boot-book"
    )
)

## Combine and cite
refs <- c(rref, bref)
cite("R, boot-package", refs)

## Cite numerically
savestyle <- tools::getBibstyle()
tools::bibstyle("JSSnumbered", .init = TRUE,
  fmtPrefix = function(paper) paste0("[", paper$.index, "]"),
  cite = function(key, bib, ...)
    citeNatbib(key, bib, mode = "numbers",
      bibpunct = c("[", "]", ";", "n", " ", ",", "...")
    )
cite("R, boot-package", refs, textual = TRUE)
refs

## restore the old style
tools::bibstyle(savestyle, .default = TRUE)

```

citEntry

*Bibliography Entries (Older Interface)*

## Description

Old interface providing functionality for specifying bibliographic information in enhanced BibTeX style. Since R 2.14.0 this has been superseded by [bibentry](#).

## Usage

```
citEntry(entry, textVersion = NULL, header = NULL, footer = NULL, ...)
```

## Arguments

|             |   |
|-------------|---|
| entry       | a character string with a BibTeX entry type. See section <b>Entry Types</b> in <a href="#">bibentry</a> for details.  |
| textVersion | a character string with a text representation of the reference to optionally be employed for printing.  |
| header      | a character string with optional header text.   |
| footer      | a character string with optional footer text.   |
| ...         | for <code>citEntry</code> , arguments of the form <i>tag=value</i> giving the fields of the entry, with <i>tag</i> and <i>value</i> the name and value of the field, respectively. See section <b>Entry Fields</b> in <a href="#">bibentry</a> for details. |

## Value

`citEntry` produces an object of class "bibentry".

**See Also**

[citation](#) for more information about citing R and R packages and ‘CITATION’ files;  
[bibentry](#) for the newer functionality for representing and manipulating bibliographic information.

---

 clipboard

---

*Read/Write to/from the Clipboard in MS Windows*

---

**Description**

Transfer text between a character vector and the Windows clipboard in MS Windows (only).

**Usage**

```
getClipboardFormats(numeric = FALSE)
readClipboard(format = 13, raw = FALSE)
writeClipboard(str, format = 13)
```

**Arguments**

|         |  |
|---------|--|
| numeric | logical: should the result be in human-readable form (the default) or raw numbers? |
| format  | an integer giving the desired format.  |
| raw     | should the value be returned as a raw vector rather than as a character vector?    |
| str     | a character vector or a raw vector.  |

**Details**

The Windows clipboard offers data in a number of formats: see e.g. <https://docs.microsoft.com/en-gb/windows/desktop/dataxchg/clipboard-formats>.

The standard formats include

|                 |    |                                      |
|-----------------|----|--------------------------------------|
| CF_TEXT         | 1  | Text in the machine's locale         |
| CF_BITMAP       | 2  |                                      |
| CF_METAFILEPICT | 3  | Metafile picture                     |
| CF_SYLK         | 4  | Symbolic link                        |
| CF_DIF          | 5  | Data Interchange Format              |
| CF_TIFF         | 6  | Tagged-Image File Format             |
| CF_OEMTEXT      | 7  | Text in the OEM codepage             |
| CF_DIB          | 8  | Device-Independent Bitmap            |
| CF_PALETTE      | 9  |                                      |
| CF_PENDATA      | 10 |                                      |
| CF_RIFF         | 11 | Audio data                           |
| CF_WAVE         | 12 | Audio data                           |
| CF_UNICODETEXT  | 13 | Text in Unicode (UCS-2)              |
| CF_ENHMETAFILE  | 14 | Enhanced metafile                    |
| CF_HDROP        | 15 | Drag-and-drop data                   |
| CF_LOCALE       | 16 | Locale for the text on the clipboard |
| CF_MAX          | 17 | Shell-oriented formats               |

Applications normally make data available in one or more of these and possibly additional private formats. Use `raw = TRUE` to read binary formats, `raw = FALSE` (the default) for text formats. The current codepage is used to convert text to Unicode text, and information on that is contained in the `CF_LOCALE` format. (Take care if you are running R in a different locale from Windows. It is recommended to read as Unicode text, so that Windows does the conversion based on `CF_LOCALE`, if available.)

The `writeClipboard` function will write a character vector as text or Unicode text with standard CRLF line terminators. It will copy a raw vector directly to the clipboard without any changes. It is recommended to use Unicode text (the default) instead of text to avoid interoperability problems. (Note that R 4.2 and newer on recent systems uses UTF-8 as the native encoding but the machine's locale uses a different encoding.)

### Value

For `getClipboardFormats`, a character or integer vector of available formats, in numeric order. If non human-readable character representation is known, the number is returned.

For `readClipboard`, a character vector by default, a raw vector if `raw` is `TRUE`, or `NULL`, if the format is unavailable.

For `writeClipboard` an invisible logical indicating success or failure.

### Note

This is only available on Windows.

### See Also

[file](#) which can be used to set up a connection to a clipboard.

---

close.socket

*Close a Socket*

---

### Description

Closes the socket and frees the space in the file descriptor table. The port may not be freed immediately.

### Usage

```
close.socket(socket, ...)
```

### Arguments

|                     |  |
|---------------------|--|
| <code>socket</code> | a socket object                                    |
| <code>...</code>    | further arguments passed to or from other methods. |

### Value

logical indicating success or failure

### Author(s)

Thomas Lumley

**See Also**

[make.socket](#), [read.socket](#)

Compiling in support for sockets was optional prior to R 3.3.0: see [capabilities](#) ("sockets") to see if it is available.

---

combn

---

*Generate All Combinations of  $n$  Elements, Taken  $m$  at a Time*

---

**Description**

Generate all combinations of the elements of  $x$  taken  $m$  at a time. If  $x$  is a positive integer, returns all combinations of the elements of `seq(x)` taken  $m$  at a time. If argument `FUN` is not `NULL`, applies a function given by the argument to each point. If `simplify` is `FALSE`, returns a list; otherwise returns an [array](#), typically a [matrix](#). `...` are passed unchanged to the `FUN` function, if specified.

**Usage**

```
combn(x, m, FUN = NULL, simplify = TRUE, ...)
```

**Arguments**

|                       |  |
|-----------------------|--|
| <code>x</code>        | vector source for combinations, or integer $n$ for <code>x &lt;- seq_len(n)</code> .   |
| <code>m</code>        | number of elements to choose.  |
| <code>FUN</code>      | function to be applied to each combination; default <code>NULL</code> means the identity, i.e., to return the combination (vector of length $m$ ).   |
| <code>simplify</code> | logical indicating if the result should be simplified to an <a href="#">array</a> (typically a <a href="#">matrix</a> ); if <code>FALSE</code> , the function returns a <a href="#">list</a> . Note that when <code>simplify = TRUE</code> as by default, the dimension of the result is simply determined from <code>FUN(1st combination)</code> (for efficiency reasons). This will badly fail if <code>FUN(u)</code> is not of constant length. |
| <code>...</code>      | optionally, further arguments to <code>FUN</code> .  |

**Details**

Factors  $x$  are accepted.

**Value**

A [list](#) or [array](#), see the `simplify` argument above. In the latter case, the identity `dim(combn(n, m)) == c(m, choose(n, m))` holds.

**Author(s)**

Scott Chasalow wrote the original in 1994 for S; R package **combinat** and documentation by Vince Carey <stvjc@channing.harvard.edu>; small changes by the R core team, notably to return an array in all cases of `simplify = TRUE`, e.g., for `combn(5, 5)`.

**References**

Nijenhuis, A. and Wilf, H.S. (1978) *Combinatorial Algorithms for Computers and Calculators*; Academic Press, NY.

**See Also**

[choose](#) for fast computation of the *number* of combinations. [expand.grid](#) for creating a data frame from all combinations of factors or vectors.

**Examples**

```
combn(letters[1:4], 2)
(m <- combn(10, 5, min)) # minimum value in each combination
mm <- combn(15, 6, function(x) matrix(x, 2, 3))
stopifnot(round(choose(10, 5)) == length(m), is.array(m), # 1-dimensional
           c(2,3, round(choose(15, 6))) == dim(mm))

## Different way of encoding points:
combn(c(1,1,1,1,2,2,2,3,3,4), 3, tabulate, nbins = 4)

## Compute support points and (scaled) probabilities for a
## Multivariate-Hypergeometric(n = 3, N = c(4,3,2,1)) p.f.:
# table.mat(t(combn(c(1,1,1,1,2,2,2,3,3,4), 3, tabulate, nbins = 4)))

## Assuring the identity
for(n in 1:7)
  for(m in 0:n) stopifnot(is.array(cc <- combn(n, m)),
                        dim(cc) == c(m, choose(n, m)),
                        identical(cc, combn(n, m, identity)) || m == 1)
```

compareVersion

*Compare Two Package Version Numbers***Description**

Compare two package version numbers to see which is later.

**Usage**

```
compareVersion(a, b)
```

**Arguments**

*a*, *b*                      Character strings representing package version numbers.

**Details**

R package version numbers are of the form *x.y-z* for integers *x*, *y* and *z*, with components after *x* optionally missing (in which case the version number is older than those with the components present).

**Value**

0 if the numbers are equal, -1 if *b* is later and 1 if *a* is later (analogous to the C function `strcmp`).

Gives an R error on malformed inputs.

**See Also**

`package_version`, `library`, `packageStatus`.

**Examples**

```
compareVersion("1.0", "1.0-1")
compareVersion("7.2-0", "7.1-12")
```

---

 COMPILE

---

*Compile Files for Use with R on Unix-alikes*

---

**Description**

Compile given source files so that they can subsequently be collected into a shared object using R CMD SHLIB or an executable program using R CMD LINK. Not available on Windows.

**Usage**

```
R CMD COMPILE [options] srcfiles
```

**Arguments**

|                       |  |
|-----------------------|--|
| <code>srcfiles</code> | A list of the names of source files to be compiled. Currently, C, C++, Objective C, Objective C++ and Fortran are supported; the corresponding files should have the extensions <code>‘.c’</code> , <code>‘.cc’</code> (or <code>‘.cpp’</code> ), <code>‘.m’</code> , <code>‘.mm’</code> (or <code>‘.M’</code> ), <code>‘.f’</code> and <code>‘.f90’</code> or <code>‘.f95’</code> , respectively. |
| <code>options</code>  | A list of compile-relevant settings, or for obtaining information about usage and version of the utility.  |

**Details**

R CMD SHLIB can both compile and link files into a shared object: since it knows what run-time libraries are needed when passed C++, Fortran and Objective C(++) sources, passing source files to R CMD SHLIB is more reliable.

Objective C and Objective C++ support is optional and will work only if the corresponding compilers were available at R configure time: their main usage is on macOS.

Compilation arranges to include the paths to the R public C/C++ headers.

As this compiles code suitable for incorporation into a shared object, it generates PIC code: that might occasionally be undesirable for the main code of an executable program.

This is a make-based facility, so will not compile a source file if a newer corresponding `‘.o’` file is present.

**Note**

Some binary distributions of R have COMPILE in a separate bundle, e.g. an R-devel RPM.

This is not available on Windows.

**See Also**

The section on “Customizing package compilation” in the ‘R Administration and Installation’ manual: [RShowDoc\("R-admin"\)](#).

---

contrib.url

*Find Appropriate Paths in CRAN-like Repositories*

---

**Description**

`contrib.url` adds the appropriate type-specific path within a repository to each URL in `repos`.

**Usage**

```
contrib.url(repos, type = getOption("pkgType"))
```

**Arguments**

|                    |   |
|--------------------|---|
| <code>repos</code> | character vector, the base URL(s) of the repositories to use.                               |
| <code>type</code>  | character string, indicating which type of packages: see <a href="#">install.packages</a> . |

**Details**

If `type = "both"` this will use the source repository.

**Value**

A character vector of the same length as `repos`.

**See Also**

[setRepositories](#) to set [options\("repos"\)](#), the most common value used for argument `repos`.

[available.packages](#), [download.packages](#), [install.packages](#).

The ‘R Installation and Administration’ manual for how to set up a repository.

---

count.fields

---

*Count the Number of Fields per Line*

---

## Description

`count.fields` counts the number of fields, as separated by `sep`, in each of the lines of `file` read.

## Usage

```
count.fields(file, sep = "", quote = "\"'", skip = 0,
             blank.lines.skip = TRUE, comment.char = "#")
```

## Arguments

|                               |  |
|-------------------------------|--|
| <code>file</code>             | a character string naming an ASCII data file, or a <a href="#">connection</a> , which will be opened if necessary, and if so closed at the end of the function call. |
| <code>sep</code>              | the field separator character. Values on each line of the file are separated by this character. By default, arbitrary amounts of whitespace can separate fields.     |
| <code>quote</code>            | the set of quoting characters  |
| <code>skip</code>             | the number of lines of the data file to skip before beginning to read data.  |
| <code>blank.lines.skip</code> | logical: if TRUE blank lines in the input are ignored.   |
| <code>comment.char</code>     | character: a character vector of length one containing a single character or an empty string.  |

## Details

This used to be used by [read.table](#) and can still be useful in discovering problems in reading a file by that function.

For the handling of comments, see [scan](#).

Consistent with [scan](#), `count.fields` allows quoted strings to contain newline characters. In such a case the starting line will have the field count recorded as NA, and the ending line will include the count of all fields from the beginning of the record.

## Value

A vector with the numbers of fields found.

## See Also

[read.table](#)

## Examples

```
fil <- tempfile()
cat("NAME", "1:John", "2:Paul", file = fil, sep = "\n")
count.fields(fil, sep = ":")
unlink(fil)
```

---

create.post

*Ancillary Function for Preparing Emails and Postings*

---

## Description

An ancillary function used by [bug.report](#) and [help.request](#) to prepare emails for submission to package maintainers or to R mailing lists.

## Usage

```
create.post(instructions = character(), description = "post",
            subject = "",
            method = getOption("mailer"),
            address = "the relevant mailing list",
            ccaddress = getOption("ccaddress", ""),
            filename = "R.post", info = character())
```

## Arguments

|              |   |
|--------------|---|
| instructions | Character vector of instructions to put at the top of the template email.   |
| description  | Character string: a description to be incorporated into messages.   |
| subject      | Subject of the email. Optional except for the "mailx" method.   |
| method       | Submission method, one of "none", "mailto", "gnudoit", "ess" or (Unix only) "mailx". See 'Details'.   |
| address      | Recipient's email address, where applicable: for package bug reports sent by email this defaults to the address of the package maintainer (the first if more than one is listed). |
| ccaddress    | Optional email address for copies with the "mailx" and "mailto" methods. Use ccaddress = "" for no copy.  |
| filename     | Filename to use for setting up the email (or storing it when method is "none" or sending mail fails).   |
| info         | character vector of information to include in the template email below the 'please do not edit the information below' line.   |

## Details

What this does depends on the `method`. The function first creates a template email body.

**none** A file editor (see [file.edit](#)) is opened with instructions and the template email. When this returns, the completed email is in file `file` ready to be read/pasted into an email program.

**mailto** This opens the default email program with a template email (including address, Cc: address and subject) for you to edit and send.

This works where default mailers are set up (usual on macOS and Windows, and where `xdg-open` is available and configured on other Unix-alikes: if that fails it tries the browser set by `R_BROWSER`).

This is the 'factory-fresh' default method.

**mailx** (Unix-alikes only.) A file editor (see [file.edit](#)) is opened with instructions and the template email. When this returns, it is mailed using a Unix command line mail utility such as `mailx`, to the address (and optionally, the Cc: address) given.

`gnudoit` An (X)emacs mail buffer is opened for the email to be edited and sent: this requires the `gnudoit` program to be available. Currently `subject` is ignored.

`ess` The body of the template email is sent to `stdout`.

## Value

Invisible `NULL`.

## See Also

[bug.report](#), [help.request](#).

---

|      |                  |
|------|------------------|
| data | <i>Data Sets</i> |
|------|------------------|

---

## Description

Loads specified data sets, or list the available data sets.

## Usage

```
data(..., list = character(), package = NULL, lib.loc = NULL,
      verbose = getOption("verbose"), envir = .GlobalEnv,
      overwrite = TRUE)
```

## Arguments

|                        |  |
|------------------------|--|
| <code>...</code>       | literal character strings or names.  |
| <code>list</code>      | a character vector.  |
| <code>package</code>   | a character vector giving the package(s) to look in for data sets, or <code>NULL</code> .<br>By default, all packages in the search path are used, then the ‘data’ subdirectory (if present) of the current working directory. |
| <code>lib.loc</code>   | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known.  |
| <code>verbose</code>   | a logical. If <code>TRUE</code> , additional diagnostics are printed.  |
| <code>envir</code>     | the <a href="#">environment</a> where the data should be loaded.   |
| <code>overwrite</code> | logical: should existing objects of the same name in <code>envir</code> be replaced?   |

## Details

Currently, four formats of data files are supported:

1. files ending ‘.R’ or ‘.r’ are `source()`d in, with the R working directory changed temporarily to the directory containing the respective file. (data ensures that the `utils` package is attached, in case it had been run *via* `utils::data`.)
2. files ending ‘.RData’ or ‘.rda’ are `load()`ed.
3. files ending ‘.tab’, ‘.txt’ or ‘.TXT’ are read using `read.table(..., header = TRUE, as.is=FALSE)`, and hence result in a data frame.

4. files ending `‘.csv’` or `‘.CSV’` are read using `read.table(..., header = TRUE, sep = ";", as.is=FALSE)`, and also result in a data frame.

If more than one matching file name is found, the first on this list is used. (Files with extensions `‘.txt’`, `‘.tab’` or `‘.csv’` can be compressed, with or without further extension `‘.gz’`, `‘.bz2’` or `‘.xz’`.)

The data sets to be loaded can be specified as a set of character strings or names, or as the character vector `list`, or as both.

For each given data set, the first two types (`‘.R’` or `‘.r’`, and `‘.RData’` or `‘.rda’` files) can create several variables in the load environment, which might all be named differently from the data set. The third and fourth types will always result in the creation of a single variable with the same name (without extension) as the data set.

If no data sets are specified, `data` lists the available data sets. For each package, it looks for a data index in the `‘Meta’` subdirectory or, if this is not found, scans the `‘data’` subdirectory for data files using `list_files_with_type`. The information about available data sets is returned in an object of class `"packageIQR"`. The structure of this class is experimental. Where the datasets have a different name from the argument that should be used to retrieve them the index will have an entry like `beaver1 (beavers)` which tells us that dataset `beaver1` can be retrieved by the call `data(beavers)`.

If `lib.loc` and `package` are both `NULL` (the default), the data sets are searched for in all the currently loaded packages then in the `‘data’` directory (if any) of the current working directory.

If `lib.loc = NULL` but `package` is specified as a character vector, the specified package(s) are searched for first amongst loaded packages and then in the default libraries (see `.libPaths`).

If `lib.loc` is specified (and not `NULL`), packages are searched for in the specified libraries, even if they are already loaded from another library.

To just look in the `‘data’` directory of the current working directory, set `package = character(0)` (and `lib.loc = NULL`, the default).

## Value

A character vector of all data sets specified (whether found or not), or information about all available data sets in an object of class `"packageIQR"` if none were specified.

## Good practice

There is no requirement for `data(foo)` to create an object named `foo` (nor to create one object), although it much reduces confusion if this convention is followed (and it is enforced if datasets are lazy-loaded).

`data()` was originally intended to allow users to load datasets from packages for use in their examples, and as such it loaded the datasets into the workspace `.GlobalEnv`. This avoided having large datasets in memory when not in use: that need has been almost entirely superseded by lazy-loading of datasets.

The ability to specify a dataset by name (without quotes) is a convenience: in programming the datasets should be specified by character strings (with quotes).

Use of `data` within a function without an `envir` argument has the almost always undesirable side-effect of putting an object in the user’s workspace (and indeed, of replacing any object of that name already there). It would almost always be better to put the object in the current evaluation environment by `data(..., envir = environment())`. However, two alternatives are usually preferable, both described in the `‘Writing R Extensions’` manual.

- For sets of data, set up a package to use lazy-loading of data.
- For objects which are system data, for example lookup tables used in calculations within the function, use a file `'R/sysdata.rda'` in the package sources or create the objects by R code at package installation time.

A sometimes important distinction is that the second approach places objects in the namespace but the first does not. So if it is important that the function sees `mytable` as an object from the package, it is system data and the second approach should be used. In the unusual case that a package uses a lazy-loaded dataset as a default argument to a function, that needs to be specified by `::`, e.g., `survival::survexp.us`.

### Warning

This function creates objects in the `envir` environment (by default the user's workspace) replacing any which already existed. `data("foo")` can silently create objects other than `foo`: there have been instances in published packages where it created/replaced `.Random.seed` and hence change the seed for the session.

### Note

One can take advantage of the search order and the fact that a `'R'` file will change directory. If raw data are stored in `'mydata.txt'` then one can set up `'mydata.R'` to read `'mydata.txt'` and pre-process it, e.g., using `transform()`. For instance one can convert numeric vectors to factors with the appropriate labels. Thus, the `'R'` file can effectively contain a metadata specification for the plaintext formats.

### See Also

[help](#) for obtaining documentation on data sets, [save](#) for *creating* the second (`'rda'`) kind of data, typically the most efficient one.

The 'Writing R Extensions' manual for considerations in preparing the `'data'` directory of a package.

### Examples

```
require(utils)
data() # list all available data sets
try(data(package = "rpart"), silent = TRUE) # list the data sets in the rpart package
data(USArrests, "VADeaths") # load the data sets 'USArrests' and 'VADeaths'
## Not run: ## Alternatively
ds <- c("USArrests", "VADeaths"); data(list = ds)
## End(Not run)
help(USArrests) # give information on data set 'USArrests'
```

### Description

A spreadsheet-like editor for entering or editing data.

**Usage**

```
data.entry(..., Modes = NULL, Names = NULL)
dataentry(data, modes)
de(..., Modes = list(), Names = NULL)
```

**Arguments**

|                    |   |
|--------------------|---|
| <code>...</code>   | A list of variables: currently these should be numeric or character vectors or list containing such vectors.                  |
| <code>Modes</code> | The modes to be used for the variables.   |
| <code>Names</code> | The names to be used for the variables.   |
| <code>data</code>  | A list of numeric and/or character vectors.   |
| <code>modes</code> | A list of length up to that of <code>data</code> giving the modes of (some of) the variables. <code>list()</code> is allowed. |

**Details**

The data entry editor is only available on some platforms and GUIs. Where available it provides a means to visually edit a matrix or a collection of variables (including a data frame) as described in the Notes section.

`data.entry` has side effects, any changes made in the spreadsheet are reflected in the variables. Function `de` and the internal functions `de.ncols`, `de.setup` and `de.restore` are designed to help achieve these side effects. If the user passes in a matrix, `X` say, then the matrix is broken into columns before `dataentry` is called. Then on return the columns are collected and glued back together and the result assigned to the variable `X`. If you don't want this behaviour use `dataentry` directly.

The primitive function is `dataentry`. It takes a list of vectors of possibly different lengths and modes (the second argument) and opens a spreadsheet with these variables being the columns. The columns of the data entry window are returned as vectors in a list when the spreadsheet is closed.

`de.ncols` counts the number of columns which are supplied as arguments to `data.entry`. It attempts to count columns in lists, matrices and vectors. `de.setup` sets things up so that on return the columns can be regrouped and reassigned to the correct name. This is handled by `de.restore`.

**Value**

`de` and `dataentry` return the edited value of their arguments. `data.entry` invisibly returns a vector of variable names but its main value is its side effect of assigning new version of those variables in the user's workspace.

**Resources**

The data entry window responds to X resources of class `R_dataentry`. Resources `foreground`, `background` and `geometry` are utilized.

**Note**

The details of interface to the data grid may differ by platform and GUI. The following description applies to the X11-based implementation under Unix.

You can navigate around the grid using the cursor keys or by clicking with the (left) mouse button on any cell. The active cell is highlighted by thickening the surrounding rectangle. Moving to the

right or down will scroll the grid as needed: there is no constraint to the rows or columns currently in use.

There are alternative ways to navigate using the keys. Return and (keypad) Enter and LineFeed all move down. Tab moves right and Shift-Tab move left. Home moves to the top left.

PageDown or Control-F moves down a page, and PageUp or Control-B up by a page. End will show the last used column and the last few rows used (in any column).

Using any other key starts an editing process on the currently selected cell: moving away from that cell enters the edited value whereas Esc cancels the edit and restores the previous value. When the editing process starts the cell is cleared. In numerical columns (the default) only letters making up a valid number (including `- . eE`) are accepted, and entering an invalid edited value (such as blank) enters NA in that cell. The last entered value can be deleted using the BackSpace or Del(ete) key. Only a limited number of characters (currently 29) can be entered in a cell, and if necessary only the start or end of the string will be displayed, with the omissions indicated by `>` or `<`. (The start is shown except when editing.)

Entering a value in a cell further down a column than the last used cell extends the variable and fills the gap (if any) by NAs (not shown on screen).

The column names can only be selected by clicking in them. This gives a popup menu to select the column type (currently Real (numeric) or Character) or to change the name. Changing the type converts the current contents of the column (and converting from Character to Real may generate NAs.) If changing the name is selected the header cell becomes editable (and is cleared). As with all cells, the value is entered by moving away from the cell by clicking elsewhere or by any of the keys for moving down (only).

New columns are created by entering values in them (and not by just assigning a new name). The mode of the column is auto-detected from the first value entered: if this is a valid number it gives a numeric column. Unused columns are ignored, so adding data in `var5` to a three-column grid adds one extra variable, not two.

The Copy button copies the currently selected cell: paste copies the last copied value to the current cell, and right-clicking selects a cell *and* copies in the value. Initially the value is blank, and attempts to paste a blank value will have no effect.

Control-L will refresh the display, recalculating field widths to fit the current entries.

In the default mode the column widths are chosen to fit the contents of each column, with a default of 10 characters for empty columns. you can specify fixed column widths by setting option `de.cellwidth` to the required fixed width (in characters). (set it to zero to return to variable widths). The displayed width of any field is limited to 600 pixels (and by the window width).

## See Also

[vi](#), [edit](#): edit uses `dataentry` to edit data frames.

## Examples

```
# call data entry with variables x and y
## Not run: data.entry(x, y)
```

---

debugcall*Debug a Call*

---

## Description

Set or unset debugging flags based on a call to a function. Takes into account S3/S4 method dispatch based on the classes of the arguments in the call.

## Usage

```
debugcall(call, once = FALSE)
undebugcall(call)
```

## Arguments

|      |   |
|------|---|
| call | An R expression calling a function. The called function will be debugged. See <a href="#">Details</a> . |
| once | logical; if TRUE, debugging only occurs once, as via <a href="#">debugonce</a> . Defaults to FALSE      |

## Details

`debugcall` debugs the non-generic function, S3 method or S4 method that would be called by evaluating `call`. Thus, the user does not need to specify the signature when debugging methods. Although the call is actually to the generic, it is the method that is debugged, not the generic, except for non-standard S3 generics (see [isS3stdGeneric](#)).

## Value

`debugcall` invisibly returns the debugged call expression.

## Note

Non-standard evaluation is used to retrieve the `call` (via [substitute](#)). For this reason, passing a variable containing a call expression, rather than the call expression itself, will not work.

## See Also

[debug](#) for the primary debugging interface

## Examples

```
## Not run:
## Evaluate call after setting debugging
##
f <- factor(1:10)
res <- eval(debugcall(summary(f)))

## End(Not run)
```

## Description

Functions to dump the evaluation environments (frames) and to examine dumped frames.

## Usage

```

dump.frames(dumpto = "last.dump", to.file = FALSE,
            include.GlobalEnv = FALSE)
debugger(dump = last.dump)

limitedLabels(value, maxwidth = getOption("width") - 5L)

```

## Arguments

|                                |  |
|--------------------------------|--|
| <code>dumpto</code>            | a character string. The name of the object or file to dump to.   |
| <code>to.file</code>           | logical. Should the dump be to an R object or to a file?   |
| <code>include.GlobalEnv</code> | logical indicating if a <i>copy</i> of the <code>.GlobalEnv</code> environment should be included in addition to the <code>sys.frames()</code> . Will be particularly useful when used in a batch job. |
| <code>dump</code>              | an R dump object created by <code>dump.frames</code> .   |
| <code>value</code>             | a <i>list</i> of <i>calls</i> to be formatted, e.g., for user menus.   |
| <code>maxwidth</code>          | optional length to which to trim the result of <code>limitedLabels()</code> ; values smaller than 40 or larger than 1000 are winsorized.   |

## Details

To use post-mortem debugging, set the option `error` to be a call to `dump.frames`. By default this dumps to an R object `last.dump` in the workspace, but it can be set to dump to a file (a dump of the object produced by a call to `save`). The dumped object contain the call stack, the active environments and the last error message as returned by `geterrmessage`.

When dumping to file, `dumpto` gives the name of the dumped object and the file name has `'.rda'` appended.

A dump object of class `"dump.frames"` can be examined by calling `debugger`. This will give the error message and a list of environments from which to select repeatedly. When an environment is selected, it is copied and the `browser` called from within the copy. Note that not all the information in the original frame will be available, e.g. promises which have not yet been evaluated and the contents of any `...` argument.

If `dump.frames` is installed as the error handler, execution will continue even in non-interactive sessions. See the examples for how to dump and then quit.

`limitedLabels(v)` takes a *list* of calls whose elements may have a `srcref` attribute and returns a vector that pastes a formatted version of those attributes onto the formatted version of the elements, all finally `strtrim()` med to `maxwidth`.

**Value**

Invisible NULL.

**Note**

Functions such as `sys.parent` and `environment` applied to closures will not work correctly inside `debugger`.

If the error occurred when computing the default value of a formal argument the debugger will report “recursive default argument reference” when trying to examine that environment.

Of course post-mortem debugging will not work if R is too damaged to produce and save the dump, for example if it has run out of workspace.

function() stop("test dump.frames")
<environment: 759818>
Browse[1]>
```

```

Available environments had calls:
1: f()
2: g()
3: stop("test dump.frames")

Enter an environment number, or 0 to exit
Selection: 0

## A possible setting for non-interactive sessions
options(error = quote({dump.frames(to.file = TRUE); q(status = 1)}))

## End(Not run)

```

demo

*Demonstrations of R Functionality*

## Description

`demo` is a user-friendly interface to running some demonstration R scripts. `demo()` gives the list of available topics.

## Usage

```

demo(topic, package = NULL, lib.loc = NULL,
      character.only = FALSE, verbose = getOption("verbose"),
      type = c("console", "html"), echo = TRUE,
      ask = getOption("demo.ask"),
      encoding = getOption("encoding"))

```

## Arguments

|                             |  |
|-----------------------------|--|
| <code>topic</code>          | the topic which should be demonstrated, given as a <a href="#">name</a> or literal character string, or a character string, depending on whether <code>character.only</code> is <code>FALSE</code> (default) or <code>TRUE</code> . If omitted, the list of available topics is displayed.           |
| <code>package</code>        | a character vector giving the packages to look into for demos, or <code>NULL</code> . By default, all packages in the search path are used.  |
| <code>lib.loc</code>        | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.   |
| <code>character.only</code> | logical; if <code>TRUE</code> , use <code>topic</code> as character string.  |
| <code>verbose</code>        | a logical. If <code>TRUE</code> , additional diagnostics are printed.  |
| <code>type</code>           | character: whether to show output in the console or a browser (using the dynamic help system). The latter is honored only in interactive sessions and if the <a href="#">knitr</a> package is installed. Several other arguments are silently ignored in that case, including <code>lib.loc</code> . |
| <code>echo</code>           | a logical. If <code>TRUE</code> , show the R input when sourcing.  |

|          |   |
|----------|---|
| ask      | a logical (or "default") indicating if <code>devAskNewPage</code> ( <code>ask = TRUE</code> ) should be called before graphical output happens from the demo code. The value "default" (the factory-fresh default) means to ask if <code>echo == TRUE</code> and the graphics device appears to be interactive. This parameter applies both to any currently opened device and to any devices opened by the demo code. If this is evaluated to <code>TRUE</code> and the session is <a href="#">interactive</a> , the user is asked to press RETURN to start. |
| encoding | See <a href="#">source</a> . If the package has a declared encoding, that takes preference.   |

### Details

If no topics are given, `demo` lists the available demos. For `type = "console"`, the corresponding information is returned in an object of class `"packageIQR"`.

### See Also

[source](#) and [devAskNewPage](#) which are called by `demo`. [example](#) to run code in the Examples section of help pages.

### Examples

```
demo() # for attached packages

## All available demos:
demo(package = .packages(all.available = TRUE))

## Display a demo, pausing between pages
demo(lm.glm, package = "stats", ask = TRUE)

## Display it without pausing
demo(lm.glm, package = "stats", ask = FALSE)

## Not run:
ch <- "scoping"
demo(ch, character = TRUE)

## End(Not run)

## Find the location of a demo
system.file("demo", "lm.glm.R", package = "stats")
```

---

DLL.version

---

DLL Version Information on MS Windows

---

### Description

On MS Windows only, return the version of the package and the version of R used to build the DLL, if available.

### Usage

```
DLL.version(path)
```

**Arguments**

`path` character vector of length one giving the complete path to the DLL.

**Value**

If the DLL does not exist, `NULL`.

A character vector of length two, giving the DLL version and the version of R used to build the DLL. If the information is not available, the corresponding string is empty.

**Note**

This is only available on Windows.

**Examples**

```
if(.Platform$OS.type == "windows") withAutoprint({
  DLL.version(file.path(R.home("bin"), "R.dll"))
  DLL.version(file.path(R.home(), "library/stats/libs", .Platform$r_arch, "stats.dll"))
})
```

---

download.file

*Download File from the Internet*

---

**Description**

This function can be used to download a file from the Internet.

**Usage**

```
download.file(url, destfile, method, quiet = FALSE, mode = "w",
  cacheOK = TRUE,
  extra = getOption("download.file.extra"),
  headers = NULL, ...)
```

**Arguments**

|                       |  |
|-----------------------|--|
| <code>url</code>      | a <a href="#">character</a> string (or longer vector for the "libcurl" method) naming the URL of a resource to be downloaded.  |
| <code>destfile</code> | a character string (or vector, see the <code>url</code> argument) with the file path where the downloaded file is to be saved. Tilde-expansion is performed.   |
| <code>method</code>   | Method to be used for downloading files. Current download methods are "internal", "libcurl", "wget", "curl" and "wininet" (Windows only), and there is a value "auto": see 'Details' and 'Note'. The method can also be set through the option "download.file.method": see <a href="#">options()</a> . |
| <code>quiet</code>    | If TRUE, suppress status messages (if any), and the progress bar.  |
| <code>mode</code>     | character. The mode with which to write the file. Useful values are "w", "wb" (binary), "a" (append) and "ab". Not used for methods "wget" and "curl". See also 'Details', notably about using "wb" for Windows.   |
| <code>cacheOK</code>  | logical. Is a server-side cached value acceptable?   |

|         |   |
|---------|---|
| extra   | character vector of additional command-line arguments for the "wget" and "curl" methods.  |
| headers | named character vector of additional HTTP headers to use in HTTP[S] requests. It is ignored for non-HTTP[S] URLs. The User-Agent header taken from the HTTPUserAgent option (see <a href="#">options</a> ) is automatically used as the first header. |
| ...     | allow additional arguments to be passed, unused.  |

## Details

The function `download.file` can be used to download a single file as described by `url` from the internet and store it in `destfile`.

The `url` must start with a scheme such as 'http://', 'https://' or 'file://'. Which methods support which schemes varies by R version, but `method = "auto"` will try to find a method which supports the scheme.

For `method = "auto"` (the default) currently the "internal" method is used for 'file://' URLs and "libcurl" for all others.

Support for method "libcurl" was optional on Windows prior to R 4.2.0: use `capabilities("libcurl")` to see if it is supported on an earlier version. It uses an external library of that name (<https://curl.se/libcurl/>) against which R can be compiled.

When method "libcurl" is used, there is support for simultaneous downloads, so `url` and `destfile` can be character vectors of the same length greater than one (but the method has to be specified explicitly and not *via* "auto"). For a single URL and `quiet = FALSE` a progress bar is shown in interactive use.

Nowadays the "internal" method only supports the 'file://' scheme (for which it is the default). On Windows the "wininet" method currently supports 'file://' and (but deprecated with a warning) 'http://' and 'https://' schemes.

For methods "wget" and "curl" a system call is made to the tool given by `method`, and the respective program must be installed on your system and be in the search path for executables. They will block all other activity on the R process until they complete: this may make a GUI unresponsive.

`cacheOK = FALSE` is useful for 'http://' and 'https://' URLs: it will attempt to get a copy directly from the site rather than from an intermediate cache. It is used by [available.packages](#).

The "libcurl" and "wget" methods follow 'http://' and 'https://' redirections to any scheme they support. (For method "curl" use argument `extra = "-L"`. To disable redirection in wget, use `extra = "--max-redirect=0"`.) The "wininet" method supports some redirections but not all. (For method "libcurl", messages will quote the endpoint of redirections.)

See [url](#) for how 'file://' URLs are interpreted, especially on Windows. The "internal" and "wininet" methods do not percent-decode, but the "libcurl" and "curl" methods do: method "wget" does not support them.

Most methods do not percent-encode special characters such as spaces in URLs (see [URLencode](#)), but it seems the "wininet" method does.

The remaining details apply to the "wininet" and "libcurl" methods only.

The timeout for many parts of the transfer can be set by the option `timeout` which defaults to 60 seconds. This is often insufficient for downloads of large files (50MB or more) and so should be increased when `download.file` is used in packages to do so. Note that the user can set the default timeout by the environment variable `R_DEFAULT_INTERNET_TIMEOUT` in recent versions of R, so to ensure that this is not decreased packages should use something like

```
options(timeout = max(300, getOption("timeout")))
```

(It is unrealistic to require download times of less than 1s/MB.)

The level of detail provided during transfer can be set by the `quiet` argument and the `internet.info` option: the details depend on the platform and scheme. For the "libcurl" method values of the option less than 2 give verbose output.

A progress bar tracks the transfer platform-specifically:

**On Windows** If the file length is known, the full width of the bar is the known length. Otherwise the initial width represents 100 Kbytes and is doubled whenever the current width is exceeded. (In non-interactive use this uses a text version. If the file length is known, an equals sign represents 2% of the transfer completed: otherwise a dot represents 10Kb.)

**On a Unix-alike** If the file length is known, an equals sign represents 2% of the transfer completed: otherwise a dot represents 10Kb.

The choice of binary transfer (`mode = "wb"` or `"ab"`) is important on Windows, since unlike Unix-alikes it does distinguish between text and binary files and for text transfers changes `'\n'` line endings to `'\r\n'` (aka `'CRLF'`).

On Windows, if `mode` is not supplied (`missing()`) and `url` ends in one of `'gz'`, `'bz2'`, `'xz'`, `'tgz'`, `'zip'`, `'jar'`, `'rda'`, `'rds'`, `'RData'` or `'pdf'`, `mode = "wb"` is set so that a binary transfer is done to help unwary users.

Code written to download binary files must use `mode = "wb"` (or `"ab"`), but the problems incurred by a text transfer will only be seen on Windows.

## Value

An (invisible) integer code, 0 for success and non-zero for failure. For the "wget" and "curl" methods this is the status code returned by the external program. The "internal" method can return 1, but will in most cases throw an error.

What happens to the destination file(s) in the case of error depends on the method and R version. Currently the "internal", "wininet" and "libcurl" methods will remove the file if the URL is unavailable except when `mode` specifies appending when the file should be unchanged.

## Setting Proxies

For the Windows-only method "wininet", the 'Internet Options' of the system are used to choose proxies and so on; these are set in the Control Panel and are those used for system browsers.

For the "libcurl" and "curl" methods, proxies can be set *via* the environment variables `http_proxy` or `ftp_proxy`. See <https://curl.se/libcurl/c/libcurl-tutorial.html> for further details.

## Secure URLs

Methods which access `'https://'` and (where supported) `'ftps://'` URLs should try to verify the site certificates. This is usually done using the CA root certificates installed by the OS (although we have seen instances in which these got removed rather than updated). For further information see <https://curl.se/docs/sslcerts.html>.

On Windows with `method = "libcurl"`, the CA root certificates are provided by the OS when R was linked with libcurl with Schannel enabled, which is the current default in Rtools. This can be verified by checking that `libcurlVersion()` returns a version

string containing `"Schannel"`. If it does not, for verification to be on the environment variable `CURL_CA_BUNDLE` must be set to a path to a certificate bundle file, usually named `'ca-bundle.crt'` or `'curl-ca-bundle.crt'`. (This is normally done automatically for a binary installation of R, which installs `'R_HOME/etc/curl-ca-bundle.crt'` and sets `CURL_CA_BUNDLE` to point to it if that environment variable is not already set.) For an updated certificate bundle, see <https://curl.se/docs/sslcerts.html>. Currently one can download a copy from <https://raw.githubusercontent.com/bagder/ca-bundle/master/ca-bundle.crt> and set `CURL_CA_BUNDLE` to the full path to the downloaded file.

On Windows with `method = "libcurl"`, when R was linked with `libcurl` with `Schannel` enabled, the connection fails if it cannot be established that the certificate has not been revoked. Some MITM proxies present particularly in corporate environments do not work with this behavior. It can be changed by setting environment variable `R_LIBCURL_SSL_REVOKE_BEST_EFFORT` to `TRUE`, with the consequence of reducing security.

Note that the root certificates used by R may or may not be the same as used in a browser, and indeed different browsers may use different certificate bundles (there is typically a build option to choose either their own or the system ones).

### Good practice

Setting the `method` should be left to the end user. Neither of the `wget` nor `curl` commands is widely available: you can check if one is available via `Sys.which`, and should do so in a package or script.

If you use `download.file` in a package or script, you must check the return value, since it is possible that the download will fail with a non-zero status but not an R error.

The supported `methods` do change: `method libcurl` was introduced in R 3.2.0 and was optional on Windows until R 4.2.0 – use `capabilities("libcurl")` in a program to see if it is available.

### 'ftp://' URLs

Most modern browsers do not support such URLs, and `'https://'` ones are much preferred for use in R. `'ftp://'` URLs have always been rare, and are nowadays even less supported.

It is intended that R will continue to allow such URLs for as long as `libcurl` does, but as they become rarer this is increasingly untested. What 'protocols' the version of `libcurl` being used supports can be seen by calling `libcurlVersion()`.

These URLs are accessed using the FTP protocol which has a number of variants. One distinction is between 'active' and '(extended) passive' modes: which is used is chosen by the client. The `"libcurl"` method uses passive mode which was almost universally used by browsers before they dropped support altogether.

### Note

Files of more than 2GB are supported on 64-bit builds of R; they may be truncated on some 32-bit builds.

Methods `"wget"` and `"curl"` are mainly for historical compatibility but provide may provide capabilities not supported by the `"libcurl"` or `"wininet"` methods.

Method `"wget"` can be used with proxy firewalls which require user/password authentication if proper values are stored in the configuration file for `wget`.

`wget` (<https://www.gnu.org/software/wget/>) is commonly installed on Unix-alikes (but not macOS). Windows binaries are available from MSYS2 and elsewhere.

`curl` (<https://curl.se/>) is installed on macOS and increasingly commonly on Unix-alikes. Windows binaries are available at that URL.

### See Also

`options` to set the `HTTPUserAgent`, `timeout` and `internet.info` options used by some of the methods.

`url` for a finer-grained way to read data from URLs.

`url.show`, `available.packages`, `download.packages` for applications.

Contributed packages **RCurl** and **curl** provide more comprehensive facilities to download from URLs.

---

download.packages    *Download Packages from CRAN-like Repositories*

---

### Description

These functions can be used to automatically compare the version numbers of installed packages with the newest available version on the repositories and update outdated packages on the fly.

### Usage

```
download.packages(pkgs, destdir, available = NULL,
                  repos = getOption("repos"),
                  contriburl = contrib.url(repos, type),
                  method, type = getOption("pkgType"), ...)
```

### Arguments

|                         |  |
|-------------------------|--|
| <code>pkgs</code>       | character vector of the names of packages whose latest available versions should be downloaded from the repositories.  |
| <code>destdir</code>    | directory where downloaded packages are to be stored.  |
| <code>available</code>  | an object as returned by <code>available.packages</code> listing packages available at the repositories, or <code>NULL</code> which makes an internal call to <code>available.packages</code> .                          |
| <code>repos</code>      | character vector, the base URL(s) of the repositories to use, i.e., the URL of the CRAN master such as <code>"https://cran.r-project.org"</code> or ones of its mirrors, <code>"https://cloud.r-project.org"</code> .    |
| <code>contriburl</code> | URL(s) of the contrib sections of the repositories. Use this argument only if your repository mirror is incomplete, e.g., because you burned only the ‘contrib’ section on a CD. Overrides argument <code>repos</code> . |
| <code>method</code>     | Download method, see <code>download.file</code> .  |
| <code>type</code>       | character string, indicate which type of packages: see <code>install.packages</code> and ‘Details’.  |
| <code>...</code>        | additional arguments to be passed to <code>download.file</code> and <code>available.packages</code> .  |

## Details

`download.packages` takes a list of package names and a destination directory, downloads the newest versions and saves them in `destdir`. If the list of available packages is not given as argument, it is obtained from repositories. If a repository is local, i.e. the URL starts with `"file:"`, then the packages are not downloaded but used directly. Both `"file:"` and `"file://"` are allowed as prefixes to a file path. Use the latter only for URLs: see [url](#) for their interpretation. (Other forms of `'file://'` URLs are not supported.)

For `download.packages`, `type = "both"` looks at source packages only.

## Value

A two-column matrix of names and destination file names of those packages successfully downloaded. If packages are not available or there is a problem with the download, suitable warnings are given.

## See Also

[available.packages](#), [contrib.url](#).

The main use is by [install.packages](#).

See [download.file](#) for how to handle proxies and other options to monitor file transfers.

The ‘R Installation and Administration’ manual for how to set up a repository.

---

edit

*Invoke a Text Editor*

---

## Description

Invoke a text editor on an R object.

## Usage

```
edit(name, ...)
## Default S3 method:
edit(name = NULL, file = "", title = NULL,
      editor = getOption("editor"), ...)
```

```
vi(name = NULL, file = "")
emacs(name = NULL, file = "")
pico(name = NULL, file = "")
xemacs(name = NULL, file = "")
xedit(name = NULL, file = "")
```

## Arguments

|                    |   |
|--------------------|---|
| <code>name</code>  | a named object that you want to edit. For the default method, if <code>name</code> is missing then the file specified by <code>file</code> is opened for editing. |
| <code>file</code>  | a string naming the file to write the edited version to.  |
| <code>title</code> | a display name for the object being edited.   |

`editor` usually a character string naming (or giving the path to) the text editor you want to use. On Unix the default is set from the environment variables `EDITOR` or `VISUAL` if either is set, otherwise `vi` is used. On Windows it defaults to `"internal"`, the script editor. On the macOS GUI the argument is ignored and the document editor is always used.

`editor` can also be an R function, in which case it is called with the arguments `name`, `file`, and `title`. Note that such a function will need to independently implement all desired functionality.

... further arguments to be passed to or from methods.

## Details

`edit` invokes the text editor specified by `editor` with the object `name` to be edited. It is a generic function, currently with a default method and one for data frames and matrices.

`data.entry` can be used to edit data, and is used by `edit` to edit matrices and data frames on systems for which `data.entry` is available.

It is important to realize that `edit` does not change the object called `name`. Instead, a copy of `name` is made and it is that copy which is changed. Should you want the changes to apply to the object `name` you must assign the result of `edit` to `name`. (Try `fix` if you want to make permanent changes to an object.)

In the form `edit(name)`, `edit` deparses `name` into a temporary file and invokes the editor `editor` on this file. Quitting from the editor causes `file` to be parsed and that value returned. Should an error occur in parsing, possibly due to incorrect syntax, no value is returned. Calling `edit()`, with no arguments, will result in the temporary file being reopened for further editing.

Note that deparsing is not perfect, and the object recreated after editing can differ in subtle ways from that deparsed: see `dput` and `.deparseOpts`. (The deparse options used are the same as the defaults for `dump`.) Editing a function will preserve its environment. See `edit.data.frame` for further changes that can occur when editing a data frame or matrix.

Currently only the internal editor in Windows makes use of the `title` option; it displays the given `name` in the window header.

## Note

The functions `vi`, `emacs`, `pico`, `xemacs`, `xedit` rely on the corresponding editor being available and being on the path. This is system-dependent.

## See Also

`edit.data.frame`, `data.entry`, `fix`.

## Examples

```
## Not run:
# use xedit on the function mean and assign the changes
mean <- edit(mean, editor = "xedit")

# use vi on mean and write the result to file mean.out
vi(mean, file = "mean.out")

## End(Not run)
```

## Description

Use data editor on data frame or matrix contents.

## Usage

```
## S3 method for class 'data.frame'
edit(name, factor.mode = c("character", "numeric"),
      edit.row.names = any(row.names(name) != 1:nrow(name)), ...)

## S3 method for class 'matrix'
edit(name, edit.row.names = !is.null(dn[[1]]), ...)
```

## Arguments

|                             |  |
|-----------------------------|--|
| <code>name</code>           | A data frame or (numeric, logical or character) matrix.  |
| <code>factor.mode</code>    | How to handle factors (as integers or using character levels) in a data frame. Can be abbreviated.   |
| <code>edit.row.names</code> | logical. Show the row names (if they exist) be displayed as a separate editable column? It is an error to ask for this on a matrix with <code>NULL</code> row names. |
| <code>...</code>            | further arguments passed to or from other methods.   |

## Details

At present, this only works on simple data frames containing numeric, logical or character vectors and factors, and numeric, logical or character matrices. Any other mode of matrix will give an error, and a warning is given when the matrix has a class (which will be discarded).

Data frame columns are coerced on input to *character* unless numeric (in the sense of `is.numeric`), logical or factor. A warning is given when classes are discarded. Special characters (tabs, non-printing ASCII, etc.) will be displayed as escape sequences.

Factors columns are represented in the spreadsheet as either numeric vectors (which are more suitable for data entry) or character vectors (better for browsing). After editing, vectors are padded with NA to have the same length and factor attributes are restored. The set of factor levels can not be changed by editing in numeric mode; invalid levels are changed to NA and a warning is issued. If new factor levels are introduced in character mode, they are added at the end of the list of levels in the order in which they encountered.

It is possible to use the data-editor's facilities to select the mode of columns to swap between numerical and factor columns in a data frame. Changing any column in a numerical matrix to character will cause the result to be coerced to a character matrix. Changing the mode of logical columns is not supported.

For a data frame, the row names will be taken from the original object if `edit.row.names = FALSE` and the number of rows is unchanged, and from the edited output if `edit.row.names = TRUE` and there are no duplicates. (If the `row.names` column is incomplete, it is extended by entries like `row223`.) In all other cases the row names are replaced by `seq(length = nrow)`.

For a matrix, colnames will be added (of the form `col7`) if needed. The rownames will be taken from the original object if `edit.row.names = FALSE` and the number of rows is unchanged (otherwise `NULL`), and from the edited output if `edit.row.names = TRUE`. (If the `row.names` column is incomplete, it is extended by entries like `row223`.)

Editing a matrix or data frame will lose all attributes apart from the row and column names.

### Value

The edited data frame or matrix.

### Note

`fix(dataframe)` works for in-place editing by calling this function.

If the data editor is not available, a dump of the object is presented for editing using the default method of `edit`.

At present the data editor is limited to 65535 rows.

example

*Run an Examples Section from the Online Help*

---

### Description

Run all the **R** code from the **Examples** part of R's online help topic `topic`, with possible exceptions due to `\dontrun`, `\dontshow`, and `\donttest` tags, see 'Details' below.

### Usage

```
example(topic, package = NULL, lib.loc = NULL,
        character.only = FALSE, give.lines = FALSE, local = FALSE,
        type = c("console", "html"), echo = TRUE,
        verbose = getOption("verbose"),
        setRNG = FALSE, ask = getOption("example.ask"),
        prompt.prefix = abbreviate(topic, 6),
        catch.aborts = FALSE,
        run.dontrun = FALSE, run.donttest = interactive())
```

## Arguments

|                             |  |
|-----------------------------|--|
| <code>topic</code>          | name or literal character string: the online <a href="#">help</a> topic the examples of which should be run.   |
| <code>package</code>        | a character vector giving the package names to look into for the topic, or <code>NULL</code> (the default), when all packages on the <a href="#">search</a> path are used.   |
| <code>lib.loc</code>        | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.   |
| <code>character.only</code> | a logical indicating whether <code>topic</code> can be assumed to be a character string.   |
| <code>give.lines</code>     | logical: if true, the <i>lines</i> of the example source code are returned as a character vector.  |
| <code>local</code>          | logical: if <code>TRUE</code> evaluate locally, if <code>FALSE</code> evaluate in the workspace.   |
| <code>type</code>           | character: whether to show output in the console or a browser (using the dynamic help system). The latter is honored only in interactive sessions and if the <a href="#">knitr</a> package is installed. Several other arguments are silently ignored in that case, including <code>setRNG</code> and <code>lib.loc</code> .   |
| <code>echo</code>           | logical; if <code>TRUE</code> , show the R input when sourcing.  |
| <code>verbose</code>        | logical; if <code>TRUE</code> , show even more when running example code.  |
| <code>setRNG</code>         | logical or expression; if not <code>FALSE</code> , the random number generator state is saved, then initialized to a specified state, the example is run and the (saved) state is restored. <code>setRNG = TRUE</code> sets the same state as R CMD <a href="#">check</a> does for running a package's examples. This is currently equivalent to <code>setRNG = {RNGkind("default", "default", "default"); set.seed(1)}</code> . |
| <code>ask</code>            | logical (or "default") indicating if <a href="#">devAskNewPage</a> ( <code>ask = TRUE</code> ) should be called before graphical output happens from the example code. The value "default" (the factory-fresh default) means to ask if <code>echo</code> is true and the graphics device appears to be interactive. This parameter applies both to any currently opened device and to any devices opened by the example code.    |
| <code>prompt.prefix</code>  | character; prefixes the prompt to be used if <code>echo</code> is true (as it is by default).  |
| <code>catch.aborts</code>   | logical, passed on to <a href="#">source()</a> , indicating that "abort"ing errors should be caught.   |
| <code>run.dontrun</code>    | logical indicating that <code>\dontrun</code> should be ignored, i.e., do run the enclosed code.   |
| <code>run.donttest</code>   | logical indicating that <code>\donttest</code> should be ignored, i.e., do run the enclosed code.  |

## Details

If `lib.loc` is not specified, the packages are searched for amongst those already loaded, then in the libraries given by [.libPaths\(\)](#). If `lib.loc` is specified, packages are searched for only in the specified libraries, even if they are already loaded from another library. The search stops at the first package found that has help on the topic.

An attempt is made to load the package before running the examples, but this will not replace a package loaded from another location.

If `local = TRUE` objects are not created in the workspace and so not available for examination after `example` completes: on the other hand they cannot overwrite objects of the same name in the workspace.

As detailed in the ‘Writing R Extensions’ manual, the author of the help page can tag parts of the examples with the following exception rules:

`\dontrun` encloses code that should not be run.

`\dontshow` encloses code that is invisible on help pages, but will be run both by the package checking tools, and the `example()` function. This was previously `\testonly`, and that form is still accepted.

`\donttest` encloses code that typically should be run, but not during package checking. The default `run.donttest = interactive()` leads `example()` use in other help page examples to skip `\donttest` sections appropriately.

The additional `\dontdiff` tag (in  $R \geq 4.4.0$ ) produces special comments in the code run by `example` (for `Rdiff`-based testing of example output), but does not affect which code is run or displayed on the help page.

## Value

The value of the last evaluated expression, unless `give.lines` is true, where a `character` vector is returned.

lengths(lmex)
```

file.edit

*Edit One or More Files***Description**

Edit one or more files in a text editor.

**Usage**

```
file.edit(..., title = file, editor = getOption("editor"),
          fileEncoding = "")
```

**Arguments**

|                           |  |
|---------------------------|--|
| <code>...</code>          | one or more character vectors containing the names of the files to be displayed. These will be tilde-expanded: see <a href="#">path.expand</a> .     |
| <code>title</code>        | the title to use in the editor; defaults to the filename.  |
| <code>editor</code>       | the text editor to be used, usually as a character string naming (or giving the path to) the text editor you want to use See ‘Details’.              |
| <code>fileEncoding</code> | the encoding to assume for the file: the default is to assume the native encoding. See the ‘Encoding’ section of the help for <a href="#">file</a> . |

**Details**

The behaviour of this function is very system-dependent. Currently files can be opened only one at a time on Unix; on Windows, the internal editor allows multiple files to be opened, but has a limit of 50 simultaneous edit windows.

The `title` argument is used for the window caption in Windows, and is currently ignored on other platforms.

Any error in re-encoding the files to the native encoding will cause the function to fail.

The default for `editor` is system-dependent. On Windows it defaults to "internal", the script editor, and in the macOS GUI the document editor is used whatever the value of `editor`. On Unix the default is set from the environment variables `EDITOR` or `VISUAL` if either is set, otherwise `vi` is used.

`editor` can also be an R function, in which case it is called with the arguments `name`, `file`, and `title`. Note that such a function will need to independently implement all desired functionality.

On Windows, UTF-8-encoded paths not valid in the current locale can be used.

[files](#), [file.show](#), [edit](#), [fix](#),

**Examples**

```
## Not run:
# open two R scripts for editing
file.edit("script1.R", "script2.R")

## End(Not run)
```

## Description

Utility for shell-style file tests.

## Usage

```
file_test(op, x, y)
```

## Arguments

|      |  |
|------|--|
| op   | a character string specifying the test to be performed. Unary tests (only x is used) are "-f" (existence and not being a directory), "-d" (existence and directory), "-L" or "-h" (existence and symbolic link), "-x" (executable as a file or searchable as a directory), "-w" (writable) and "-r" (readable). Binary tests are "-nt" (strictly newer than, using the modification dates) and "-ot" (strictly older than): in both cases the test is false unless both files exist. |
| x, y | character vectors giving file paths.   |

## Details

'Existence' here means being on the file system and accessible by the `stat` system call (or a 64-bit extension) – on a Unix-alike this requires execute permission on all of the directories in the path that leads to the file, but no permissions on the file itself.

For the meaning of "-x" on Windows see [file.access](#).

## See Also

[file.exists](#) which only tests for existence (`test -e` on some systems) but not for not being a directory.

[file.path](#), [file.info](#)

## Examples

```
dir <- file.path(R.home(), "library", "stats")
file_test("-d", dir)
file_test("-nt", file.path(dir, "R"), file.path(dir, "demo"))
```

---

|                |                                    |
|----------------|------------------------------------|
| findCRANmirror | <i>Find CRAN Mirror Preference</i> |
|----------------|------------------------------------|

---

## Description

Find out if a CRAN mirror has been selected for the current session.

## Usage

```
findCRANmirror(type = c("src", "web"))
```

## Arguments

|      |  |
|------|--|
| type | Is the mirror to be used for package sources or web information? |
|------|--|

## Details

Find out if a CRAN mirror has been selected for the current session. If so, return its URL else return `"https://CRAN.R-project.org"`.

The mirror is looked for in several places.

- The value of the environment variable `R_CRAN_SRC` or `R_CRAN_WEB` (depending on `type`), if set.
- An entry in `getOption("repos")` named `'CRAN'` which is not the default `"@CRAN@"`.
- The `'CRAN'` URL entry in the `'repositories'` file (see [setRepositories](#)), if it is not the default `"@CRAN@"`.

The two types allow for partial local CRAN mirrors, for example those mirroring only the package sources where `getOption("repos")` might point to the partial mirror and `R_CRAN_WEB` point to a full (remote) mirror.

## Value

A character string.

## See Also

[setRepositories](#), [chooseCRANmirror](#)

## Examples

```
c(findCRANmirror("src"), findCRANmirror("web"))

Sys.setenv(R_CRAN_WEB = "https://cloud.r-project.org")
c(findCRANmirror("src"), findCRANmirror("web"))
```

---

|             |  |
|-------------|--|
| findLineNum | <i>Find the Location of a Line of Source Code, or Set a Breakpoint There</i> |
|-------------|--|

---

## Description

These functions locate objects containing particular lines of source code, using the information saved when the code was parsed with `keep.source = TRUE`.

## Usage

```
findLineNum(srcfile, line, nameonly = TRUE,
            envir = parent.frame(), lastenv)

setBreakpoint(srcfile, line, nameonly = TRUE,
              envir = parent.frame(), lastenv, verbose = TRUE,
              tracer, print = FALSE, clear = FALSE, ...)
```

## Arguments

|                       |  |
|-----------------------|--|
| <code>srcfile</code>  | The name of the file containing the source code.   |
| <code>line</code>     | The line number within the file. See Details for an alternate way to specify this.   |
| <code>nameonly</code> | If <code>TRUE</code> (the default), we require only a match to <code>basename(srcfile)</code> , not to the full path.            |
| <code>envir</code>    | Where do we start looking for function objects?  |
| <code>lastenv</code>  | Where do we stop? See the Details.   |
| <code>verbose</code>  | Should we print information on where breakpoints were set?   |
| <code>tracer</code>   | An optional <code>tracer</code> function to pass to <code>trace</code> . By default, a call to <code>browser</code> is inserted. |
| <code>print</code>    | The <code>print</code> argument to pass to <code>trace</code> .  |
| <code>clear</code>    | If <code>TRUE</code> , call <code>untrace</code> rather than <code>trace</code> .  |
| <code>...</code>      | Additional arguments to pass to <code>trace</code> .   |

## Details

The `findLineNum` function searches through all objects in environment `envir`, its parent, grand-parent, etc., all the way back to `lastenv`.

`lastenv` defaults to the global environment if `envir` is not specified, and to the root environment `emptyenv()` if `envir` is specified. (The first default tends to be quite fast, and will usually find all user code other than S4 methods; the second one is quite slow, as it will typically search all attached system libraries.)

For convenience, `envir` may be specified indirectly: if it is not an environment, it will be replaced with `environment(envir)`.

`setBreakpoint` is a simple wrapper function for `trace` and `untrace`. It will set or clear breakpoints at the locations found by `findLineNum`.

The `srcfile` is normally a filename entered as a character string, but it may be a "`srcfile`" object, or it may include a suffix like "`filename.R#nn`", in which case the number `nn` will be used as a default value for `line`.

As described in the description of the `where` argument on the man page for `trace`, the R package system uses a complicated scheme that may include more than one copy of a function in a package. The user will typically see the public one on the search path, while code in the package will see a private one in the package namespace. If you set `envir` to the environment of a function in the package, by default `findLineNum` will find both versions, and `setBreakpoint` will set the breakpoint in both. (This can be controlled using `lastenv`; e.g., `envir = environment(foo)`, `lastenv = globalenv()` will find only the private copy, as the search is stopped before seeing the public copy.)

S version 4 methods are also somewhat tricky to find. They are stored with the generic function, which may be in the **base** or other package, so it is usually necessary to have `lastenv = emptyenv()` in order to find them. In some cases transformations are done by R when storing them and `findLineNum` may not be able to find the original code. Many special cases, e.g. methods on primitive generics, are not yet supported.

### Value

`findLineNum` returns a list of objects containing location information. A `print` method is defined for them.

`setBreakpoint` has no useful return value; it is called for the side effect of calling `trace` or `untrace`.

### Author(s)

Duncan Murdoch

### See Also

`trace`

### Examples

```
## Not run:
# Find what function was defined in the file mysource.R at line 100:
findLineNum("mysource.R#100")

# Set a breakpoint in both copies of that function, assuming one is in the
# same namespace as myfunction and the other is on the search path
setBreakpoint("mysource.R#100", envir = myfunction)

## End(Not run)
```

---

fix

*Fix an Object*

---

### Description

`fix` invokes `edit` on `x` and then assigns the new (edited) version of `x` in the user's workspace.

### Usage

```
fix(x, ...)
```

## Arguments

- `x`                      the name of an R object, as a name or a character string.
- `...`                    arguments to pass to editor: see [edit](#).

## Details

The name supplied as `x` need not exist as an R object, in which case a function with no arguments and an empty body is supplied for editing.

Editing an R object may change it in ways other than are obvious: see the comment under [edit](#). See [edit.data.frame](#) for changes that can occur when editing a data frame or matrix.

## See Also

[edit](#), [edit.data.frame](#)

## Examples

```
## Not run:
## Assume 'my.fun' is a user defined function :
fix(my.fun)
## now my.fun is changed
## Also,
fix(my.data.frame) # calls up data editor
fix(my.data.frame, factor.mode="char") # use of ...

## End(Not run)
```

---

flush.console

*Flush Output to a Console*

---

## Description

This does nothing except on console-based versions of R. On the macOS and Windows GUIs, it ensures that the display of output in the console is current, even if output buffering is on.

## Usage

```
flush.console()
```

format

*Format Unordered and Ordered Lists***Description**

Format unordered (itemize) and ordered (enumerate) lists.

**Usage**

```
formatUL(x, label = "*", offset = 0,
         width = 0.9 * getOption("width"))
formatOL(x, type = "arabic", offset = 0, start = 1,
         width = 0.9 * getOption("width"))
```

**Arguments**

|                     |  |
|---------------------|--|
| <code>x</code>      | a character vector of list items.  |
| <code>label</code>  | a character string used for labelling the items.   |
| <code>offset</code> | a non-negative integer giving the offset (indentation) of the list.  |
| <code>width</code>  | a positive integer giving the target column for wrapping lines in the output.  |
| <code>type</code>   | a character string specifying the ‘type’ of the labels in the ordered list. If "arabic" (default), arabic numerals are used. For "Alph" or "alph", single upper or lower case letters are employed (in this case, the number of the last item must not exceed 26). Finally, for "Roman" or "roman", the labels are given as upper or lower case roman numerals (with the number of the last item maximally 3999). <code>type</code> can be given as a unique abbreviation of the above, or as one of the HTML style tokens "1" (arabic), "A"/"a" (alphabetic), or "I"/"i" (roman), respectively. |
| <code>start</code>  | a positive integer specifying the starting number of the first item in an ordered list.  |

**Value**

A character vector with the formatted entries.

**See Also**

[formatDL](#) for formatting description lists.

**Examples**

```
## A simpler recipe.
x <- c("Mix dry ingredients thoroughly.",
      "Pour in wet ingredients.",
      "Mix for 10 minutes.",
      "Bake for one hour at 300 degrees.")
## Format and output as an unordered list.
writeLines(formatUL(x))
## Format and output as an ordered list.
writeLines(formatOL(x))
## Ordered list using lower case roman numerals.
```

```
writeLines(formatOL(x, type = "i"))
## Ordered list using upper case letters and some offset.
writeLines(formatOL(x, type = "A", offset = 5))
```

---

|             |   |
|-------------|---|
| getAnywhere | <i>Retrieve an R Object, Including from a Namespace</i> |
|-------------|---|

---

## Description

These functions locate all objects with name matching their argument, whether visible on the search path, registered as an S3 method or in a namespace but not exported. `getAnywhere()` returns the objects and `argsAnywhere()` returns the arguments of any objects that are functions.

## Usage

```
getAnywhere(x)
argsAnywhere(x)
```

## Arguments

`x` a character string or name.

## Details

These functions look at all loaded namespaces, whether or not they are associated with a package on the search list.

They do not search literally “anywhere”: for example, local evaluation frames and namespaces that are not loaded will not be searched.

Where functions are found as registered S3 methods, an attempt is made to find which namespace registered them. This may not be correct, especially if namespaces have been unloaded.

## Value

For `getAnywhere()` an object of class “getAnywhere”. This is a list with components

|                      |  |
|----------------------|--|
| <code>name</code>    | the name searched for  |
| <code>objs</code>    | a list of objects found                                      |
| <code>where</code>   | a character vector explaining where the object(s) were found |
| <code>visible</code> | logical: is the object visible                               |
| <code>dups</code>    | logical: is the object identical to one earlier in the list. |

In computing whether objects are identical, their environments are ignored.

Normally the structure will be hidden by the `print` method. There is a `[` method to extract one or more of the objects found.

For `argsAnywhere()` one or more argument lists as returned by [args](#).

## See Also

[getS3method](#) to find the method which would be used: this might not be the one of those returned by `getAnywhere` since it might have come from a namespace which was unloaded or be registered under another name.

[get](#), [getFromNamespace](#), [args](#)

## Examples

```
getAnywhere("format.dist")
getAnywhere("simpleLoess") # not exported from stats
argsAnywhere(format.dist)
```

---

getFromNamespace      *Utility Functions for Developing Namespaces*

---

## Description

Utility functions to access and replace the non-exported functions in a namespace, for use in developing packages with namespaces.

They should not be used in production code (except perhaps `assignInMyNamespace`, but see the ‘Note’).

## Usage

```
getFromNamespace(x, ns, pos = -1, envir = as.environment(pos))

assignInNamespace(x, value, ns, pos = -1,
                  envir = as.environment(pos))

assignInMyNamespace(x, value)

fixInNamespace(x, ns, pos = -1, envir = as.environment(pos), ...)
```

## Arguments

|                    |   |
|--------------------|---|
| <code>x</code>     | an object name (given as a character string).               |
| <code>value</code> | an R object.  |
| <code>ns</code>    | a namespace, or character string giving the namespace.      |
| <code>pos</code>   | where to look for the object: see <a href="#">get</a> .     |
| <code>envir</code> | an alternative way to specify an environment to look in.    |
| <code>...</code>   | arguments to pass to the editor: see <a href="#">edit</a> . |

## Details

`assignInMyNamespace` is intended to be called from functions within a package, and chooses the namespace as the environment of the function calling it.

The namespace can be specified in several ways. Using, for example, `ns = "stats"` is the most direct, but a loaded package can be specified via any of the methods used for [get](#): `ns` can also be the environment printed as ‘<namespace:foo>’.

`getFromNamespace` is similar to (but predates) the `:::` operator: it is more flexible in how the namespace is specified.

`fixInNamespace` invokes [edit](#) on the object named `x` and assigns the revised object in place of the original object. For compatibility with `fix`, `x` can be unquoted.

**Value**

getFromNamespace returns the object found (or gives an error).

assignInNamespace, assignInMyNamespace and fixInNamespace are invoked for their side effect of changing the object in the namespace.

**Warning**

assignInNamespace should not be used in final code, and will in future throw an error if called from a package. Already certain uses are disallowed.

**Note**

assignInNamespace, assignInMyNamespace and fixInNamespace change the copy in the namespace, but not any copies already exported from the namespace, in particular an object of that name in the package (if already attached) and any copies already imported into other namespaces. They are really intended to be used *only* for objects which are not exported from the namespace. They do attempt to alter a copy registered as an S3 method if one is found.

They can only be used to change the values of objects in the namespace, not to create new objects.

**See Also**

[get](#), [fix](#), [getS3method](#)

**Examples**

```
getFromNamespace("findGeneric", "utils")
## Not run:
fixInNamespace("predict.ppr", "stats")
stats:::predict.ppr
getS3method("predict", "ppr")
## alternatively
fixInNamespace("predict.ppr", pos = 3)
fixInNamespace("predict.ppr", pos = "package:stats")

## End(Not run)
```

---

getParseData

*Get Detailed Parse Information from Object*

---

**Description**

If the "keep.source" option is TRUE, R's parser will attach detailed information on the object it has parsed. These functions retrieve that information.

**Usage**

```
getParseData(x, includeText = NA)
getParseText(parseData, id)
```

## Arguments

|                          |  |
|--------------------------|--|
| <code>x</code>           | an expression returned from <code>parse</code> , or a function or other object with source reference information |
| <code>includeText</code> | logical; whether to include the text of parsed items in the result   |
| <code>parseData</code>   | a data frame returned from <code>getParseData</code>   |
| <code>id</code>          | a vector of item identifiers whose text is to be retrieved   |

## Details

In version 3.0.0, the R parser was modified to include code written by Romain Francois in his **parser** package. This constructs a detailed table of information about every token and higher level construct in parsed code. This table is stored in the `srcfile` record associated with source references in the parsed code, and retrieved by the `getParseData` function.

## Value

For `getParseData`:

If parse data is not present, `NULL`. Otherwise a data frame is returned, containing the following columns:

|                       |  |
|-----------------------|--|
| <code>line1</code>    | integer. The line number where the item starts. This is the parsed line number called "parse" in <code>getSrcLocation</code> , which ignores <code>#line</code> directives.  |
| <code>col1</code>     | integer. The column number where the item starts. The first character is column 1. This corresponds to "column" in <code>getSrcLocation</code> .   |
| <code>line2</code>    | integer. The line number where the item ends.  |
| <code>col2</code>     | integer. The column number where the item ends.  |
| <code>id</code>       | integer. An identifier associated with this item.  |
| <code>parent</code>   | integer. The <code>id</code> of the parent of this item.   |
| <code>token</code>    | character string. The type of the token.   |
| <code>terminal</code> | logical. Whether the token is "terminal", i.e. a leaf in the parse tree.   |
| <code>text</code>     | character string. If <code>includeText</code> is <code>TRUE</code> , the text of all tokens; if it is <code>NA</code> (the default), the text of terminal tokens. If <code>includeText == FALSE</code> , this column is not included. Very long strings (with source of 1000 characters or more) will not be stored; a message giving their length and delimiter will be included instead. |

The rownames of the data frame will be equal to the `id` values, and the data frame will have a "srcfile" attribute containing the `srcfile` record which was used. The rows will be ordered by starting position within the source file, with parent items occurring before their children.

For `getParseText`:

A character vector of the same length as `id` containing the associated text items. If they are not included in `parseData`, they will be retrieved from the original file.

## Note

There are a number of differences in the results returned by `getParseData` relative to those in the original **parser** code:

- Fewer columns are kept.
- The internal token number is not returned.

- `coll` starts counting at 1, not 0.
- The `id` values are not attached to the elements of the parse tree, they are only retained in the table returned by `getParseData`.
- `#line` directives are identified, but other comment markup (e.g., **roxygen** comments) are not.

Parse data by design explore details of the parser implementation, which are subject to change without notice. Applications computing on the parse data may require updates for each R release.

### Examples

```
fn <- function(x) {
  x + 1 # A comment, kept as part of the source
}

d <- getParseData(fn)
if (!is.null(d)) {
  plus <- which(d$token == "'+'")
  sum <- d$parent[plus]
  print(d[as.character(sum),])
  print(getParseText(d, sum))
}
```

---

getS3method

*Get an S3 Method*

---

### Description

Get a method for an S3 generic, possibly from a namespace or the generic's registry.

### Usage

```
getS3method(f, class, optional = FALSE, envir = parent.frame())
```

### Arguments

|                       |   |
|-----------------------|---|
| <code>f</code>        | a character string giving the name of the generic.                                      |
| <code>class</code>    | a character string giving the name of the class.  |
| <code>optional</code> | logical: should failure to find the generic or a method be allowed?                     |
| <code>envir</code>    | the <a href="#">environment</a> in which the method and its generic are searched first. |

## Details

S3 methods may be hidden in namespaces, and will not then be found by `get`: this function can retrieve such functions, primarily for debugging purposes.

Further, S3 methods can be registered on the generic when a namespace is loaded, and the registered method will be used if none is visible (using namespace scoping rules).

It is possible that which S3 method will be used may depend on where the generic `f` is called from: `getS3method` returns the method found if `f` were called from the same environment.

## Value

The function found, or `NULL` if no function is found and `optional = TRUE`.

## See Also

`methods`, `get`, `getAnywhere`

## Examples

```
require(stats)
exists("predict.ppr") # false
getS3method("predict", "ppr")
```

---

getWindowsHandle      *Get a Windows Handle*

---

## Description

Get the Windows handle of a window or of the R process in MS Windows.

## Usage

```
getWindowsHandle(which = "Console")
```

## Arguments

`which`                      a string (see below), or the number of a graphics device window (which must a `windows` one).

## Details

`getWindowsHandle` gets the Windows handle. Possible choices for `which` are:

|                 |  |
|-----------------|--|
| "Console"       | The console window handle.             |
| "Frame"         | The MDI frame window handle.           |
| "Process"       | The process pseudo-handle.             |
| A device number | The window handle of a graphics device |

These values are not normally useful to users, but may be used by developers making addons to R. `NULL` is returned for the Frame handle if not running in MDI mode, for the Console handle when running Rterm, for any unrecognized string for `which`, or for a graphics device with no corresponding window.

Other windows (help browsers, etc.) are not accessible through this function.

**Value**

An external pointer holding the Windows handle, or `NULL`.

**Note**

This is only available on Windows.

**See Also**

[getIdentification](#), [getWindowsHandles](#)

**Examples**

```
if(.Platform$OS.type == "windows")
  print( getWindowsHandle() )
```

---

`getWindowsHandles`    *Get handles of Windows in the MS Windows RGui*

---

**Description**

This function gets the Windows handles of visible top level windows or windows within the R MDI frame (when using the Rgui).

**Usage**

```
getWindowsHandles(which = "R", pattern = "", minimized = FALSE)
```

**Arguments**

|                        |  |
|------------------------|--|
| <code>which</code>     | A vector of strings "R" or "all" (possibly with repetitions). See the Details section. |
| <code>pattern</code>   | A vector of patterns that the titles of the windows must match.                        |
| <code>minimized</code> | A logical vector indicating whether minimized windows should be considered.            |

**Details**

This function will search for Windows handles, for passing to external GUIs or to the [arrangeWindows](#) function. Each of the arguments may be a vector of values. These will be treated as follows:

- The arguments will all be recycled to the same length.
- The corresponding elements of each argument will be applied in separate searches.
- The final result will be the union of the windows identified in each of the searches.

If an element of `which` is "R", only windows belonging to the current R process will be returned. In MDI mode, those will be the child windows within the R GUI (Rgui) frame. In SDI mode, all windows belonging to the process will be included.

If the element is "all", then top level windows will be returned.

The elements of `pattern` will be used to make a subset of windows whose title text matches (according to [grep](#)) the pattern.

If `minimized = FALSE`, minimized windows will be ignored.

### Value

A list of external pointers containing the window handles.

### Note

This is only available on Windows.

### Author(s)

Duncan Murdoch

### See Also

[arrangeWindows](#), [getWindowsHandle](#) (singular).

### Examples

```
if(.Platform$OS.type == "windows") withAutoprint({
  getWindowsHandles()
  getWindowsHandles("all")
})
```

---

glob2rx

*Change Wildcard or Globbing Pattern into Regular Expression*

---

### Description

Change *wildcard* aka *globbing* patterns into the corresponding regular expressions ([regexp](#)).

This is also a practical didactical example for the use of [sub\(\)](#) and regular expressions.

### Usage

```
glob2rx(pattern, trim.head = FALSE, trim.tail = TRUE)
```

### Arguments

|                        |   |
|------------------------|---|
| <code>pattern</code>   | character vector  |
| <code>trim.head</code> | logical specifying if leading " <code>^.*</code> " should be trimmed from the result.   |
| <code>trim.tail</code> | logical specifying if trailing " <code>.*\$</code> " should be trimmed from the result. |

## Details

This takes a wildcard as used by most shells and returns an equivalent regular expression. ‘?’ is mapped to ‘.’ (match a single character), ‘\*’ to ‘.’ (match any string, including an empty one), and the pattern is anchored (it must start at the beginning and end at the end). Optionally, the resulting regexp is simplified.

Note that now even ‘(’, ‘[’ and ‘{’ can be used in `pattern`, but `glob2rx()` may not work correctly with arbitrary characters in `pattern`, for example escaped special characters.

## Value

A character vector of the same length as the input `pattern` where each wildcard is translated to the corresponding regular expression.

## Author(s)

Martin Maechler, Unix/sed based version, 1991; current: 2004

## See Also

[regexp](#) about regular expression, [sub](#), etc about substitutions using regexps. [Sys.glob](#) does wildcard expansio, i.e., “globbing” on file paths more subtly, e.g., allowing to escape special characters.

## Examples

```
stopifnot(glob2rx("abc.*") == "^abc\\.\"",
  glob2rx("a?b.*") == "^a.b\\.\"",
  glob2rx("a?b.*", trim.tail = FALSE) == "^a.b\\.\\.\\.*$\"",
  glob2rx("*.doc") == "^.*\\.\\.doc$",
  glob2rx("*.doc", trim.head = TRUE) == "\\\\.\\.doc$",
  glob2rx("*.t*") == "^.*\\.\\.t\"",
  glob2rx("*.t??") == "^.*\\.\\.t\\.\\.\"",
  glob2rx("[*]") == "^.*\\["
)
```

---

|                 |  |
|-----------------|--|
| globalVariables | <i>Declarations Used in Checking a Package</i> |
|-----------------|--|

---

## Description

For `globalVariables`, the names supplied are of functions or other objects that should be regarded as defined globally when the `check` tool is applied to this package. The call to `globalVariables` will be included in the package’s source. Repeated calls in the same package accumulate the names of the global variables.

Typical examples are the fields and methods in reference classes, which appear to be global objects to `codetools`. (This case is handled automatically by `setRefClass()` and friends, using the supplied field and method names.)

For `suppressForeignCheck`, the names supplied are of variables used as `.NAME` in foreign function calls which should not be checked by `checkFF(registration = TRUE)`. Without this declaration, expressions other than simple character strings are assumed to evaluate to registered native symbol objects. The type of call (`.Call`, `.External`, etc.) and argument counts will be

checked. With this declaration, checks on those names will usually be suppressed. (If the code uses an expression that should only be evaluated at runtime, the message can be suppressed by wrapping it in a `dontCheck` function call, or by saving it to a local variable, and suppressing messages about that variable. See the example below.)

### Usage

```
globalVariables(names, package, add = TRUE)
suppressForeignCheck(names, package, add = TRUE)
```

### Arguments

|         |   |
|---------|---|
| names   | The character vector of object names. If omitted, the current list of global variables declared in the package will be returned, unchanged.   |
| package | The relevant package, usually the character string name of the package but optionally its corresponding namespace environment.<br>When the call to <code>globalVariables</code> or <code>suppressForeignCheck</code> comes in the package's source file, the argument is normally omitted, as in the example below. |
| add     | Should the contents of <code>names</code> be added to the current global variables or replace it?   |

### Details

The lists of declared global variables and native symbol objects are stored in a metadata object in the package's namespace, assuming the `globalVariables` or `suppressForeignCheck` call(s) occur as top-level calls in the package's source code.

The check command, as implemented in package `tools`, queries the list before checking the R source code in the package for possible problems.

`globalVariables` was introduced in R 2.15.1 and `suppressForeignCheck` was introduced in R 3.1.0 so both should be used conditionally: see the example.

### Value

`globalVariables` returns the current list of declared global variables, possibly modified by this call.

`suppressForeignCheck` returns the current list of native symbol objects which are not to be checked.

### Note

The global variables list really belongs to a restricted scope (a function or a group of method definitions, for example) rather than the package as a whole. However, implementing finer control would require changes in `check` and/or in `codetools`, so in this version the information is stored at the package level.

### Author(s)

John Chambers and Duncan Murdoch

### See Also

`dontCheck`.

**Examples**

```
## Not run:
## assume your package has some code that assigns ".obj1" and ".obj2"
## but not in a way that codetools can find.
## In the same source file (to remind you that you did it) add:
if(getRversion() >= "2.15.1") utils::globalVariables(c(".obj1", ".obj2"))

## To suppress messages about a run-time calculated native symbol,
## save it to a local variable.

## At top level, put this:
if(getRversion() >= "3.1.0") utils::suppressForeignCheck("localvariable")

## Within your function, do the call like this:
localvariable <- if (condition) entry1 else entry2
.Call(localvariable, 1, 2, 3)

## HOWEVER, it is much better practice to write code
## that can be checked thoroughly, e.g.
if(condition) .Call(entry1, 1, 2, 3) else .Call(entry2, 1, 2, 3)

## End(Not run)
```

hashtab

*Hash Tables (Experimental)***Description**

Create and manipulate mutable hash tables.

**Usage**

```
hashtab(type = c("identical", "address"), size)
gethash(h, key, nomatch = NULL)
sethash(h, key, value)
remhash(h, key)
numhash(h)
typhash(h)
maphash(h, FUN)
clrhash(h)
is.hashtab(x)
## S3 method for class 'hashtab'
h[[key, nomatch = NULL, ...]]
## S3 replacement method for class 'hashtab'
h[[key, ...]] <- value
## S3 method for class 'hashtab'
print(x, ...)
## S3 method for class 'hashtab'
format(x, ...)
## S3 method for class 'hashtab'
length(x)
## S3 method for class 'hashtab'
str(object, ...)
```

## Arguments

|                        |   |
|------------------------|---|
| <code>type</code>      | a <a href="#">character</a> string specifying the hash table type.                          |
| <code>size</code>      | an integer specifying the expected number of entries.                                       |
| <code>h, object</code> | a hash table.   |
| <code>key</code>       | an R object to use as a key.  |
| <code>nomatch</code>   | value to return if <code>key</code> does not match.   |
| <code>value</code>     | new value to associate with <code>key</code> .  |
| <code>FUN</code>       | a <a href="#">function</a> of two arguments, the key and the value, to call for each entry. |
| <code>x</code>         | object to be tested, printed, or formatted.   |
| <code>...</code>       | additional arguments.   |

## Details

Hash tables are a data structure for efficiently associating keys with values. Hash tables are similar to [environments](#), but keys can be arbitrary objects. Like environments, and unlike named lists and most other objects in R, hash tables are mutable, i.e., they are *not* copied when modified and assignment means just giving a new name to the same object.

New hash tables are created by `hashtab`. Two variants are available: keys can be considered to match if they are `identical()` (`type = "identical"`, the default), or if their addresses in memory are equal (`type = "address"`). The default `"identical"` type is almost always the right choice. The `size` argument provides a hint for setting the initial hash table size. The hash table will grow if necessary, but specifying an expected size can be more efficient.

`gethash` returns the value associated with `key`. If `key` is not present in the table, then the value of `nomatch` is returned.

`sethash` adds a new key/value association or changes the current value for an existing key. `remhash` removes the entry for `key`, if there is one.

`maphash` calls `FUN` for each entry in the hash table with two arguments, the entry key and the entry value. The order in which the entries are processed is not predictable. The consequence of `FUN` adding entries to the table or deleting entries from the table is also not predictable, except that removing the entry currently being processed will have the desired effect.

`clrhash` removes all entries from the hash table.

## Value

`hashtab` returns a new hash table of the specified `type`.

`gethash` returns the value associated with `key`, or `nomatch` if there is no such value.

`sethash` returns `value` invisibly.

`remhash` invisibly returns `TRUE` if an entry for `key` was found and removed, and `FALSE` if no entry was found.

`numhash` returns the current number of entries in the table.

`typhash` returns a character string specifying the type of the hash table, one of `"identical"` or `"address"`.

`maphash` and `clrhash` return `NULL` invisibly.

## Notes

The interface design is based loosely on hash table support in Common Lisp.

The hash function and equality test used for "identical" hash tables are the same as the ones used internally by `duplicated` and `unique`, with two exceptions:

- Closure environments are not ignored when comparing closures. This corresponds to calling `identical()` with `ignore.environment = FALSE`, which is the default for `identical()`.
- External pointer objects are compared as reference objects, corresponding to calling `identical()` with `extptr.as.ref = TRUE`. This ensures that hash tables with keys containing external pointers behave reasonably when serialized and unserialized.

As an experimental feature, the element operator `[ ]` can also be used get or set hash table entries, and `length` can be used to obtain the number of entries. It is not yet clear whether this is a good idea.

## Examples

```
## Create a new empty hash table.
h1 <- hashtab()
h1

## Add some key/value pairs.
sethash(h1, NULL, 1)
sethash(h1, .GlobalEnv, 2)
for (i in seq_along(LETTERS)) sethash(h1, LETTERS[i], i)

## Look up values for some keys.
gethash(h1, NULL)
gethash(h1, .GlobalEnv)
gethash(h1, "Q")

## Remove an entry.
(remhash(h1, NULL))
gethash(h1, NULL)
(remhash(h1, "XYZ"))

## Using the element operator.
h1[["ABC"]]
h1[["ABC", nomatch = 77]]
h1[["ABC"]] <- "DEF"
h1[["ABC"]]

## Integers and real numbers that are equal are considered different
## (not identical) as keys:
identical(3, 3L)
sethash(h1, 3L, "DEF")
gethash(h1, 3L)
gethash(h1, 3)

## Two variables can refer to the same hash table.
h2 <- h1
identical(h1, h2)
## set in one, see in the "other" <==> really one object with 2 names
sethash(h2, NULL, 77)
```

```
gethash(h1, NULL)
str(h1)

## An example of using maphash(): get all hashkeys of a hash table:
hashkeys <- function(h) {
  val <- vector("list", numhash(h))
  idx <- 0
  maphash(h, function(k, v) { idx <-< idx + 1
                                val[idx] <-< list(k) })
  val
}

kList <- hashkeys(h1)
str(kList) # the *order* is "arbitrary" & cannot be "known"
```

hasName

*Check for Name***Description**

hasName is a convenient way to test for one or more names in an R object.

**Usage**

```
hasName(x, name)
```

**Arguments**

|      |   |
|------|---|
| x    | Any object.                               |
| name | One or more character values to look for. |

**Details**

hasName(x, name) is defined to be equivalent to name %in% names(x), though it will evaluate slightly more quickly. It is intended to replace the common idiom !is.null(x\$name). The latter can be unreliable due to partial name matching; see the example below.

**Value**

A logical vector of the same length as name containing TRUE if the corresponding entry is in names(x).

**See Also**

[%in%, exists](#)

**Examples**

```
x <- list(abc = 1, def = 2)
!is.null(x$abc) # correct
!is.null(x$a)   # this is the wrong test!
hasName(x, "abc")
hasName(x, "a")
```

---

head

*Return the First or Last Parts of an Object*

---

## Description

Returns the first or last parts of a vector, matrix, table, data frame or function. Since `head()` and `tail()` are generic functions, they may also have been extended to other classes.

## Usage

```
head(x, ...)
## Default S3 method:
head(x, n = 6L, ...)
## S3 method for class 'matrix'
head(x, n = 6L, ...) # is exported as head.matrix()
## NB: The methods for 'data.frame' and 'array' are identical to the 'matrix' one

## S3 method for class 'ftable'
head(x, n = 6L, ...)
## S3 method for class 'function'
head(x, n = 6L, ...)

tail(x, ...)
## Default S3 method:
tail(x, n = 6L, keepnums = FALSE, addrownums, ...)
## S3 method for class 'matrix'
tail(x, n = 6L, keepnums = TRUE, addrownums, ...) # exported as tail.matrix()
## NB: The methods for 'data.frame', 'array', and 'table'
##       are identical to the 'matrix' one

## S3 method for class 'ftable'
tail(x, n = 6L, keepnums = FALSE, addrownums, ...)
## S3 method for class 'function'
tail(x, n = 6L, ...)
```

## Arguments

|          |   |
|----------|---|
| x        | an object   |
| n        | an integer vector of length up to <code>dim(x)</code> (or 1, for non-dimensioned objects). A logical is silently coerced to integer. Values specify the indices to be selected in the corresponding dimension (or along the length) of the object. A positive value of <code>n[i]</code> includes the first/last <code>n[i]</code> indices in that dimension, while a negative value excludes the last/first <code>abs(n[i])</code> , including all remaining indices. NA or non-specified values (when <code>length(n) &lt; length(dim(x))</code> ) select all indices in that dimension. Must contain at least one non-missing value. |
| keepnums | in each dimension, if no names in that dimension are present, create them using the indices included in that dimension. Ignored if <code>dim(x)</code> is NULL or its length 1.   |

`addrownums`      deprecated - `keepnums` should be used instead. Taken as the value of `keepnums` if it is explicitly set when `keepnums` is not.

`...`              arguments to be passed to or from other methods.

## Details

For vector/array based objects, `head()` (`tail()`) returns a subset of the same dimensionality as `x`, usually of the same class. For historical reasons, by default they select the first (last) 6 indices in the first dimension ("rows") or along the length of a non-dimensionalised vector, and the full extent (all indices) in any remaining dimensions. `head.matrix()` and `tail.matrix()` are exported.

The default and array(/matrix) methods for `head()` and `tail()` are quite general. They will work as is for any class which has a `dim()` method, a `length()` method (only required if `dim()` returns `NULL`), and a `[]` method (that accepts the `drop` argument and can subset in all dimensions in the dimensioned case).

For functions, the lines of the deparsed function are returned as character strings.

When `x` is an array(/matrix) of dimensionality two and more, `tail()` will add `dimnames` similar to how they would appear in a full printing of `x` for all dimensions `k` where `n[k]` is specified and non-missing and `dimnames(x)[[k]]` (or `dimnames(x)` itself) is `NULL`. Specifically, the form of the added `dimnames` will vary for different dimensions as follows:

`k=1 (rows):`    "`[n, ]`" (right justified with whitespace padding)

`k=2 (columns):` "`[ , n]`" (with *no* whitespace padding)

`k>2 (higher dims):` "`n`", i.e., the indices as *character* values

Setting `keepnums = FALSE` suppresses this behaviour.

As `data.frame` subsetting ('indexing') keeps `attributes`, so do the `head()` and `tail()` methods for data frames.

## Value

An object (usually) like `x` but generally smaller. Hence, for `arrays`, the result corresponds to `x[... , drop=FALSE]`. For `ftable` objects `x`, a transformed `format(x)`.

## Note

For array inputs the output of `tail` when `keepnums` is `TRUE`, any `dimnames` vectors added for dimensions `>2` are the original numeric indices in that dimension *as character vectors*. This means that, e.g., for 3-dimensional array `arr`, `tail(arr, c(2,2,-1))[ , , 2]` and `tail(arr, c(2,2,-1))[ , , "2"]` may both be valid but have completely different meanings.

## Author(s)

Patrick Burns, improved and corrected by R-Core. Negative argument added by Vincent Goulet. Multi-dimension support added by Gabriel Becker.

## Examples

```
head(letters)
head(letters, n = -6L)

head(freeny.x, n = 10L)
head(freeny.y)
```

```

head(iris3)
head(iris3, c(6L, 2L))
head(iris3, c(6L, -1L, 2L))

tail(letters)
tail(letters, n = -6L)

tail(freeny.x)
## the bottom-right "corner" :
tail(freeny.x, n = c(4, 2))
tail(freeny.y)

tail(iris3)
tail(iris3, c(6L, 2L))
tail(iris3, c(6L, -1L, 2L))

## iris with dimnames stripped
a3d <- iris3 ; dimnames(a3d) <- NULL
tail(a3d, c(6, -1, 2)) # keepnums = TRUE is default here!
tail(a3d, c(6, -1, 2), keepnums = FALSE)

## data frame w/ a (non-standard) attribute:
treeS <- structure(trees, foo = "bar")
(n <- nrow(treeS))
stopifnot(exprs = { # attribute is kept
  identical(htS <- head(treeS), treeS[1:6, ])
  identical(attr(htS, "foo"), "bar")
  identical(tlS <- tail(treeS), treeS[(n-5):n, ])
  ## BUT if I use "useAttrib(.)", this is *not* ok, when n is of length 2:
  ## --- because [i,j]-indexing of data frames *also* drops "other" attributes ..
  identical(tail(treeS, 3:2), treeS[(n-2):n, 2:3] )
})

tail(library) # last lines of function

head(stats::ftable(Titanic))

## 1d-array (with named dim) :
a1 <- array(1:7, 7); names(dim(a1)) <- "O2"
stopifnot(exprs = {
  identical( tail(a1, 10), a1)
  identical( head(a1, 10), a1)
  identical( head(a1, 1), a1 [1 , drop=FALSE] ) # was a1[1] in R <= 3.6.x
  identical( tail(a1, 2), a1[6:7])
  identical( tail(a1, 1), a1 [7 , drop=FALSE] ) # was a1[7] in R <= 3.6.x
})

```

## Description

help is the primary interface to the help systems.

**Usage**

```
help(topic, package = NULL, lib.loc = NULL,
      verbose = getOption("verbose"),
      try.all.packages = getOption("help.try.all.packages"),
      help_type = getOption("help_type"))
```

**Arguments**

|                               |   |
|-------------------------------|---|
| <code>topic</code>            | usually, a <a href="#">name</a> or character string specifying the topic for which help is sought. A character string (enclosed in explicit single or double quotes) is always taken as naming a topic.<br><br>If the value of <code>topic</code> is a length-one character vector the topic is taken to be the value of the only element. Otherwise <code>topic</code> must be a name or a <a href="#">reserved</a> word (if syntactically valid) or character string.<br>See ‘Details’ for what happens if this is omitted. |
| <code>package</code>          | a name or character vector giving the packages to look into for documentation, or <code>NULL</code> . By default, all packages whose namespaces are loaded are used. To avoid a name being deparsed use e.g. <code>(pkg_ref)</code> (see the examples).   |
| <code>lib.loc</code>          | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries. This is not used for HTML help (see ‘Details’).  |
| <code>verbose</code>          | logical; if <code>TRUE</code> , the file name is reported.  |
| <code>try.all.packages</code> | logical; see Note.  |
| <code>help_type</code>        | character string: the type of help required. Possible values are <code>"text"</code> , <code>"html"</code> and <code>"pdf"</code> . Case is ignored, and partial matching is allowed.   |

**Details**

The following types of help are available:

- Plain text help
- HTML help pages with hyperlinks to other topics, shown in a browser by [browseURL](#). (On Unix-alikes, where possible an existing browser window is re-used: the macOS GUI uses its own browser window.)  
If for some reason HTML help is unavailable (see [startDynamicHelp](#)), plain text help will be used instead.
- For help only, typeset as PDF – see the section on ‘Offline help’.

**On Unix-alikes:** The ‘factory-fresh’ default is text help except from the macOS GUI, which uses HTML help displayed in its own browser window.

**On Windows:** The default for the type of help is selected when R is installed – the ‘factory-fresh’ default is HTML help.

The rendering of text help will use directional quotes in suitable locales (UTF-8 and single-byte Windows locales): sometimes the fonts used do not support these quotes so this can be turned off by setting [options](#) (`useFancyQuotes = FALSE`).

`topic` is not optional: if it is omitted R will give

- If a package is specified, (text or, in interactive use only, HTML) information on the package, including hints/links to suitable help topics.
- If `lib.loc` only is specified, a (text) list of available packages.
- Help on `help` itself if none of the first three arguments is specified.

Some topics need to be quoted (by [backticks](#)) or given as a character string. These include those which cannot syntactically appear on their own such as unary and binary operators, function and control-flow [reserved](#) words (including `if`, `else`, `for`, `in`, `repeat`, `while`, `break` and `next`). The other reserved words can be used as if they were names, for example `TRUE`, `NA` and `Inf`.

If multiple help files matching `topic` are found, in interactive use a menu is presented for the user to choose one: in batch use the first on the search path is used. (For HTML help the menu will be an HTML page, otherwise a graphical menu if possible if `getOption("menu.graphics")` is true, the default.)

Note that HTML help does not make use of `lib.loc`: it will always look first in the loaded packages and then along `.libPaths()`.

## Offline help

Typeset documentation is produced by running the LaTeX version of the help page through `pdflatex`: this will produce a PDF file.

The appearance of the output can be customized through a file `'Rhelp.cfg'` somewhere in your LaTeX search path: this will be input as a LaTeX style file after `Rd.sty`. Some [environment variables](#) are consulted, notably `R_PAPERSIZE` (via `getOption("papersize")`) and `R_RD4PDF` (see ‘Making manuals’ in the ‘R Installation and Administration’ manual).

If there is a function `offline_help_helper` in the workspace or further down the search path it is used to do the typesetting, otherwise the function of that name in the `utils` namespace (to which the first paragraph applies). It should accept at least two arguments, the name of the LaTeX file to be typeset and the type (which is nowadays ignored). It accepts a third argument, `texinputs`, which will give the graphics path when the help document contains figures, and will otherwise not be supplied.

## Note

Unless `lib.loc` is specified explicitly, the loaded packages are searched before those in the specified libraries. This ensures that if a library is loaded from a library not in the known library trees, then the help from the loaded library is used. If `lib.loc` is specified explicitly, the loaded packages are *not* searched.

If this search fails and argument `try.all.packages` is `TRUE` and neither packages nor `lib.loc` is specified, then all the packages in the known library trees are searched for help on `topic` and a list of (any) packages where help may be found is displayed (with hyperlinks for `help_type = "html"`). **NB:** searching all packages can be slow, especially the first time (caching of files by the OS can expedite subsequent searches dramatically).

## See Also

`?`  for shortcuts to help topics.

`help.search()` or `??` for finding help pages on a vague topic; `help.start()` which opens the HTML version of the R help pages; `library()` for listing available packages and the help objects they contain; `data()` for listing available data sets; `methods()`.

Use `prompt()` to get a prototype for writing help pages of your own package.

## Examples

```
help()
help(help)                # the same

help(lapply)

help("for")                # or ?"for", but quotes/backticks are needed

try({# requires working TeX installation:
  help(dgamma, help_type = "pdf")
  ## -> nicely formatted pdf -- including math formula -- for help(dgamma):
  system2(getOption("pdfviewer"), "dgamma.pdf", wait = FALSE)
})

help(package = "splines") # get help even when package is not loaded

topi <- "women"
help(topi)

try(help("bs", try.all.packages = FALSE)) # reports not found (an error)
help("bs", try.all.packages = TRUE)       # reports can be found
                                           # in package 'splines'

## For programmatic use:
topic <- "family"; pkg_ref <- "stats"
help((topic), (pkg_ref))
```

---

help.request

*Send a Post to R-help*

---

## Description

Prompts the user to check they have done all that is expected of them before sending a post to the R-help mailing list, provides a template for the post with session information included and optionally sends the email (on Unix systems).

## Usage

```
help.request(subject = "",
             address = "r-help@R-project.org",
             file = "R.help.request", ...)
```

**Arguments**

|         |   |
|---------|---|
| subject | subject of the email. Please do not use single quotes (') in the subject! Post separate help requests for multiple queries. |
| address | recipient's email address.  |
| file    | filename to use (if needed) for setting up the email.   |
| ...     | additional named arguments such as <code>method</code> and <code>ccaddress</code> to pass to <code>create.post</code> .     |

**Details**

This function is not intended to replace the posting guide. Please read the guide before posting to R-help or using this function (see <https://www.r-project.org/posting-guide.html>).

The `help.request` function:

- asks whether the user has consulted relevant resources, stopping and opening the relevant URL if a negative response if given.
- checks whether the current version of R is being used and whether the add-on packages are up-to-date, giving the option of updating where necessary.
- asks whether the user has prepared appropriate (minimal, reproducible, self-contained, commented) example code ready to paste into the post.

Once this checklist has been completed a template post is prepared including current session information, and passed to `create.post`.

**Value**

Nothing useful.

**Author(s)**

Heather Turner, based on the then current code and help page of `bug.report()`.

**See Also**

The posting guide (<https://www.r-project.org/posting-guide.html>), also `sessionInfo()` from which you may add to the help request.  
`create.post`.

**Description**

Allows for searching the help system for documentation matching a given character string in the (file) name, alias, title, concept or keyword entries (or any combination thereof), using either [fuzzy matching](#) or [regular expression](#) matching. Names and titles of the matched help entries are displayed nicely formatted.

Vignette names, titles and keywords and demo names and titles may also be searched.

**Usage**

```
help.search(pattern, fields = c("alias", "concept", "title"),
            apropos, keyword, whatis, ignore.case = TRUE,
            package = NULL, lib.loc = NULL,
            help.db = getOption("help.db"),
            verbose = getOption("verbose"),
            rebuild = FALSE, agrep = NULL, use_UTF8 = FALSE,
            types = getOption("help.search.types"))

??pattern
field??pattern
```

**Arguments**

|             |  |
|-------------|--|
| pattern     | a character string to be matched in the specified fields. If this is given, the arguments <code>apropos</code> , <code>keyword</code> , and <code>whatis</code> are ignored.   |
| fields      | a character vector specifying the fields of the help database to be searched. The entries must be abbreviations of "name", "title", "alias", "concept", and "keyword", corresponding to the help page's (file) name, its title, the topics and concepts it provides documentation for, and the keywords it can be classified to. See below for details and how vignettes and demos are searched.   |
| apropos     | a character string to be matched in the help page topics and title.  |
| keyword     | a character string to be matched in the help page 'keywords'. 'Keywords' are really categories: the standard categories are listed in file <code>'R.home("doc")/KEYWORDS'</code> (see also the example) and some package writers have defined their own. If <code>keyword</code> is specified, <code>agrep</code> defaults to <code>FALSE</code> .   |
| whatis      | a character string to be matched in the help page topics.  |
| ignore.case | a logical. If <code>TRUE</code> , case is ignored during matching; if <code>FALSE</code> , pattern matching is case sensitive.   |
| package     | a character vector with the names of packages to search through, or <code>NULL</code> in which case <i>all</i> available packages in the library trees specified by <code>lib.loc</code> are searched.   |
| lib.loc     | a character vector describing the location of R library trees to search through, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known.   |
| help.db     | a character string giving the file path to a previously built and saved help database, or <code>NULL</code> .  |
| verbose     | logical; if <code>TRUE</code> , the search process is traced. Integer values are also accepted, with <code>TRUE</code> being equivalent to 2, and 1 being less verbose. On Windows a progress bar is shown during rebuilding, and on Unix a heartbeat is shown for <code>verbose = 1</code> and a package-by-package list for <code>verbose &gt;= 2</code> .   |
| rebuild     | a logical indicating whether the help database should be rebuilt. This will be done automatically if <code>lib.loc</code> or the search path is changed, or if <code>package</code> is used and a value is not found.  |
| agrep       | if <code>NULL</code> (the default unless <code>keyword</code> is used) and the character string to be matched consists of alphanumeric characters, whitespace or a dash only, approximate (fuzzy) matching via <a href="#">agrep</a> is used unless the string has fewer than 5 characters; otherwise, it is taken to contain a <a href="#">regular expression</a> to be matched via <a href="#">grep</a> . If <code>FALSE</code> , approximate matching is not used. Otherwise, one can give a numeric or a list specifying the maximal distance for the approximate match, see argument <code>max.distance</code> in the documentation for <a href="#">agrep</a> . |

|                       |  |
|-----------------------|--|
| <code>use_UTF8</code> | logical: should results be given in UTF-8 encoding? Also changes the meaning of regexps in <code>agrep</code> to be Perl regexps.  |
| <code>types</code>    | a character vector listing the types of documentation to search. The entries must be abbreviations of "vignette" "help" or "demo". Results will be presented in the order specified. |
| <code>field</code>    | a single value of <code>fields</code> to search.   |

## Details

Upon installation of a package, a pre-built `help.search` index is serialized as `'hsearch.rds'` in the `'Meta'` directory (provided the package has any help pages). Vignettes are also indexed in the `'Meta/vignette.rds'` file. These files are used to create the help search database via [hsearch\\_db](#).

The arguments `apropos` and `whatIs` play a role similar to the Unix commands with the same names.

Searching with `agrep = FALSE` will be several times faster than the default (once the database is built). However, approximate searches should be fast enough (around a second with 5000 packages installed).

If possible, the help database is saved in memory for use by subsequent calls in the session.

Note that currently the aliases in the matching help files are not displayed.

As with `?`, in `??` the pattern may be prefixed with a package name followed by `::` or `:::` to limit the search to that package.

For help files, `'\keyword'` entries which are not among the standard keywords as listed in file `'KEYWORDS'` in the R documentation directory are taken as concepts. For standard keyword entries different from `'internal'`, the corresponding descriptions from file `'KEYWORDS'` are additionally taken as concepts. All `'\concept'` entries used as concepts.

Vignettes are searched as follows. The `"name"` and `"alias"` are both the base of the vignette filename, and the `"concept"` entries are taken from the `'\VignetteKeyword'` entries. Vignettes are not classified using the help system `"keyword"` classifications. Demos are handled similarly to vignettes, without the `"concept"` search.

## Value

The results are returned in a list object of class `"hsearch"`, which has a print method for nicely formatting the results of the query. This mechanism is experimental, and may change in future versions of R.

In `R.app` on macOS, this will show up a browser with selectable items. On exiting this browser, the help pages for the selected items will be shown in separate help windows.

The internal format of the class is undocumented and subject to change.

## See Also

[hsearch\\_db](#) for more information on the help search database employed, and for utilities to inspect available concepts and keywords.

[help](#); [help.start](#) for starting the hypertext (currently HTML) version of R's online documentation, which offers a similar search mechanism.

[RSiteSearch](#) to access an on-line search of R resources.

[apropos](#) uses regexps and has nice examples.

## Examples

```

help.search("linear models")      # In case you forgot how to fit linear
                                # models
help.search("non-existent topic")

??utils::help # All the topics matching "help" in the utils package

## Documentation with topic/concept/title matching 'print'
## (disabling fuzzy matching to not also match 'point')
help.search("print", agrep = FALSE)
help.search(apropos = "print", agrep = FALSE) # ignores concepts

## Help pages with documented topics starting with 'try':
help.search("^try", fields = "alias")
alias??"^try" # the same

## Help pages documenting high-level plots:
help.search(keyword = "hplot")

RShowDoc("KEYWORDS") # show all keywords

```

---

help.start

*Hypertext Documentation*

---

## Description

Start the hypertext (currently HTML) version of R's online documentation.

## Usage

```

help.start(update = FALSE, gui = "irrelevant",
            browser = getOption("browser"), remote = NULL)

```

## Arguments

|         |   |
|---------|---|
| update  | logical: should this attempt to update the package index to reflect the currently available packages. (Not attempted if <code>remote</code> is non-NULL.)   |
| gui     | just for compatibility with S-PLUS.   |
| browser | the name of the program to be used as hypertext browser. It should be in the <code>PATH</code> , or a full path specified. Alternatively, it can be an R function which will be called with a URL as its only argument. This option is normally unset on Windows, when the file-association mechanism will be used. |
| remote  | A character string giving a valid URL for the ' <a href="#">R_HOME</a> ' directory on a remote location.  |

## Details

Unless `remote` is specified this requires the HTTP server to be available (it will be started if possible: see [startDynamicHelp](#)).

One of the links on the index page is the HTML package index, '[R\\_DOC\\_DIR/html/packages.html](#)', which can be remade by

`make.packages.html()`. For local operation, the HTTP server will remake a temporary version of this list when the link is first clicked, and each time thereafter check if updating is needed (if `.libPaths` has changed or any of the directories has been changed). This can be slow, and using `update = TRUE` will ensure that the packages list is updated before launching the index page.

Argument `remote` can be used to point to HTML help published by another R installation: it will typically only show packages from the main library of that installation.

### See Also

`help()` for on- and off-line help in other formats.

`browseURL` for how the help file is displayed.

`RSiteSearch` to access an on-line search of R resources.

### Examples

```
help.start()

## the 'remote' arg can be tested by
help.start(remote = paste0("file://", R.home()))
```

---

hsearch-utils

*Help Search Utilities*

---

### Description

Utilities for searching the help system.

### Usage

```
hsearch_db(package = NULL, lib.loc = NULL,
            types = getOption("help.search.types"),
            verbose = getOption("verbose"),
            rebuild = FALSE, use_UTF8 = FALSE)
hsearch_db_concepts(db = hsearch_db())
hsearch_db_keywords(db = hsearch_db())
```

### Arguments

|                       |  |
|-----------------------|--|
| <code>package</code>  | a character vector with the names of packages to search through, or <code>NULL</code> in which case <i>all</i> available packages in the library trees specified by <code>lib.loc</code> are searched. |
| <code>lib.loc</code>  | a character vector describing the location of R library trees to search through, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known.           |
| <code>types</code>    | a character vector listing the types of documentation to search. See <a href="#">help.search</a> for details.  |
| <code>verbose</code>  | a logical controlling the verbosity of building the help search database. See <a href="#">help.search</a> for details.   |
| <code>rebuild</code>  | a logical indicating whether the help search database should be rebuilt. See <a href="#">help.search</a> for details.  |
| <code>use_UTF8</code> | logical: should results be given in UTF-8 encoding?  |
| <code>db</code>       | a help search database as obtained by calls to <code>hsearch_db()</code> .   |

## Details

`hsearch_db()` builds and caches the help search database for subsequent use by [help.search](#). (In fact, re-builds only when forced (`rebuild = TRUE`) or “necessary”.)

The format of the help search database is still experimental, and may change in future versions. Currently, it consists of four tables: one with base information about all documentation objects found, including their names and titles and unique ids; three more tables contain the individual aliases, concepts and keywords together with the ids of the documentation objects they belong to. Separating out the latter three tables accounts for the fact that a single documentation object may provide several of these entries, and allows for efficient searching.

See the details in [help.search](#) for how searchable entries are interpreted according to help type.

`hsearch_db_concepts()` and `hsearch_db_keywords()` extract all concepts or keywords, respectively, from a help search database, and return these in a data frame together with their total frequencies and the numbers of packages they are used in, with entries sorted in decreasing total frequency.

## Examples

```
db <- hsearch_db()
## Total numbers of documentation objects, aliases, keywords and
## concepts (using the current format):
sapply(db, NROW)
## Can also be obtained from print method:
db
## 10 most frequent concepts:
head(hsearch_db_concepts(), 10)
## 10 most frequent keywords:
head(hsearch_db_keywords(), 10)
```

---

INSTALL

*Install Add-on Packages*

---

## Description

Utility for installing add-on packages.

## Usage

```
R CMD INSTALL [options] [-l lib] pkgs
```

## Arguments

|                      |  |
|----------------------|--|
| <code>pkgs</code>    | a space-separated list with the path names of the packages to be installed. See ‘Details’.   |
| <code>lib</code>     | the path name of the R library tree to install to. Also accepted in the form ‘ <code>--library=lib</code> ’. Paths including spaces should be quoted, using the conventions for the shell in use.    |
| <code>options</code> | a space-separated list of options through which in particular the process for building the help files can be controlled. Use <code>R CMD INSTALL --help</code> for the full current list of options. |

## Details

This will stop at the first error, so if you want all the `pkgs` to be tried, call this via a shell loop.

If used as `R CMD INSTALL pkgs` without explicitly specifying `lib`, packages are installed into the library tree rooted at the first directory in the library path which would be used by R run in the current environment.

To install into the library tree `lib`, use `R CMD INSTALL -l lib pkgs`. This prepends `lib` to the library path for duration of the install, so required packages in the installation directory will be found (and used in preference to those in other libraries).

Both `lib` and the elements of `pkgs` may be absolute or relative path names of directories. `pkgs` may also contain names of package archive files: these are then extracted to a temporary directory. These are tarballs containing a single directory, optionally compressed by `gzip`, `bzip2`, `xz` or `compress`. Finally, binary package archive files (as created by `R CMD INSTALL --build`) can be supplied.

Tarballs are by default unpackaged by the internal `untar` function: if needed an external `tar` command can be specified by the environment variable `R_INSTALL_TAR`: please ensure that it can handle the type of compression used on the tarball. (This is sometimes needed for tarballs containing invalid or unsupported sections, and can be faster on very large tarballs. Setting `R_INSTALL_TAR` to `'tar.exe'` has been needed to overcome permissions issues on some Windows systems.)

The package sources can be cleaned up prior to installation by `'--preclean'` or after by `'--clean'`: cleaning is essential if the sources are to be used with more than one architecture or platform.

Some package sources contain a `'configure'` script that can be passed arguments or variables via the option `'--configure-args'` and `'--configure-vars'`, respectively, if necessary. The latter is useful in particular if libraries or header files needed for the package are in non-system directories. In this case, one can use the configure variables `LIBS` and `CPPFLAGS` to specify these locations (and set these via `'--configure-vars'`), see section 'Configuration variables' in 'R Installation and Administration' for more information. (If these are used more than once on the command line they are concatenated.) The configure mechanism can be bypassed using the option `'--no-configure'`.

If the attempt to install the package fails, leftovers are removed. If the package was already installed, the old version is restored. This happens either if a command encounters an error or if the install is interrupted from the keyboard: after cleaning up the script terminates.

For details of the locking which is done, see the section 'Locking' in the help for [install.packages](#).

Option `'--build'` can be used to tar up the installed package for distribution as a binary package (as used on macOS). This is done by `utils::tar` unless environment variable `R_INSTALL_TAR` is set.

By default a package is installed with static HTML help pages if and only if R was: use options `'--html'` and `'--no-html'` to override this.

Packages are not by default installed keeping the source formatting (see the `keep.source` argument to [source](#)): this can be enabled by the option `'--with-keep.source'` or by setting environment variable `R_KEEP_PKG_SOURCE` to `yes`.

Specifying the `'--install-tests'` option copies the contents of the `'tests'` directory into the package installation. If the `R_ALWAYS_INSTALL_TESTS` environment variable is set to a true value, the tests will be installed even if `'--install-tests'` is omitted.

Use `R CMD INSTALL --help` for concise usage information, including all the available options.

## Sub-architectures

An R installation can support more than one sub-architecture: currently this is most commonly used for 32- and 64-bit builds on Windows.

For such installations, the default behaviour is to try to install source packages for all installed sub-architectures unless the package has a configure script or a 'src/Makefile' (or 'src/Makefile.win' on Windows), when only compiled code for the sub-architecture running R CMD INSTALL is installed.

To install a source package with compiled code only for the sub-architecture used by R CMD INSTALL, use '--no-multiarch'. To install just the compiled code for another sub-architecture, use '--libs-only'.

There are two ways to install for all available sub-architectures. If the configure script is known to work for both Windows architectures, use flag '--force-biarch' (and packages can specify this *via* a 'Biarch: yes' field in their DESCRIPTION files). Second, a single tarball can be installed with

```
R CMD INSTALL --merge-multiarch mypkg_version.tar.gz
```

## Staged installation

The default way to install source packages changed in R 3.6.0, so packages are first installed to a temporary location and then (if successful) moved to the destination library directory. Some older packages were written in ways that assume direct installation to the destination library.

Staged installation can currently be overridden by having a line 'StagedInstall: no' in the package's 'DESCRIPTION' file, *via* flag '--no-staged-install' or by setting environment variable R\_INSTALL\_STAGED to a false value (e.g. 'false' or 'no').

Staged installation requires either '--pkglock' or '--lock', one of which is used by default.

## Note

The options do not have to precede 'pkgs' on the command line, although it will be more legible if they do. All the options are processed before any packages, and where options have conflicting effects the last one will win.

Some parts of the operation of INSTALL depend on the R temporary directory (see [tempdir](#), usually under '/tmp') having both write and execution access to the account running R. This is usually the case, but if '/tmp' has been mounted as `noexec`, environment variable TMPDIR may need to be set to a directory from which execution is allowed.

---

install.packages     *Install Packages from Repositories or Local Files*

---

## Description

Download and install packages from CRAN-like repositories or from local files.

## Usage

```
install.packages(pkgs, lib, repos = getOption("repos"),
  contriburl = contrib.url(repos, type),
  method, available = NULL, destdir = NULL,
  dependencies = NA, type = getOption("pkgType"),
  configure.args = getOption("configure.args"),
  configure.vars = getOption("configure.vars"),
  clean = FALSE, Ncpus = getOption("Ncpus", 1L),
  verbose = getOption("verbose"),
  libs_only = FALSE, INSTALL_opts, quiet = FALSE,
  keep_outputs = FALSE, ...)
```

## Arguments

|            |   |
|------------|---|
| pkgs       | <p>character vector of the names of packages whose current versions should be downloaded from the repositories.</p> <p>If <code>repos = NULL</code>, a character vector of file paths,</p> <p><b>on Windows</b>, file paths of <code>.zip</code> files containing binary builds of packages. (<code>'http://'</code> and <code>'file://'</code> URLs are also accepted and the files will be downloaded and installed from local copies.) Source directories or file paths or URLs of archives may be specified with <code>type = "source"</code>, but some packages need suitable tools installed (see the <code>'Details'</code> section).</p> <p><b>On Unix-alikes</b>, these file paths can be source directories or archives or binary package archive files (as created by <code>R CMD build --binary</code>). (<code>'http://'</code> and <code>'file://'</code> URLs are also accepted and the files will be downloaded and installed from local copies.) On a CRAN build of R for macOS these can be <code>.tgz</code> files containing binary package archives. Tilde-expansion will be done on file paths.</p> <p>If this is missing, a listbox of available packages is presented where possible in an interactive R session.</p> |
| lib        | <p>character vector giving the library directories where to install the packages. Recycled as needed. If missing, defaults to the first element of <code>.libPaths()</code>.</p>  |
| repos      | <p>character vector, the base URL(s) of the repositories to use, e.g., the URL of a CRAN mirror such as <code>"https://cloud.r-project.org"</code>. For more details on supported URL schemes see <a href="#">url</a>.</p> <p>Can be <code>NULL</code> to install from local files, directories or URLs: this will be inferred by extension from <code>pkgs</code> if of length one.</p>  |
| contriburl | <p>URL(s) of the contrib sections of the repositories. Use this argument if your repository mirror is incomplete, e.g., because you mirrored only the <code>'contrib'</code> section, or only have binary packages. Overrides argument <code>repos</code>. Incompatible with <code>type = "both"</code>.</p>  |

|                |  |
|----------------|--|
| method         | download method, see <code>download.file</code> . Unused if a non-NULL available is supplied.  |
| available      | a matrix as returned by <code>available.packages</code> listing packages available at the repositories, or NULL when the function makes an internal call to <code>available.packages</code> . Incompatible with <code>type = "both"</code> .   |
| destdir        | directory where downloaded packages are stored. If it is NULL (the default) a subdirectory <code>downloaded_packages</code> of the session temporary directory will be used (and the files will be deleted at the end of the session).   |
| dependencies   | <p>logical indicating whether to also install uninstalled packages which these packages depend on/link to/import/suggest (and so on recursively). Not used if <code>repos = NULL</code>. Can also be a character vector, a subset of <code>c("Depends", "Imports", "LinkingTo", "Suggests", "Enhances")</code>.</p> <p>Only supported if <code>lib</code> is of length one (or missing), so it is unambiguous where to install the dependent packages. If this is not the case it is ignored, with a warning.</p> <p>The default, NA, means <code>c("Depends", "Imports", "LinkingTo")</code>. TRUE means to use <code>c("Depends", "Imports", "LinkingTo", "Suggests")</code> for <code>pkgs</code> and <code>c("Depends", "Imports", "LinkingTo")</code> for added dependencies: this installs all the packages needed to run <code>pkgs</code>, their examples, tests and vignettes (if the package author specified them correctly).</p> <p>In all of these, "LinkingTo" is omitted for binary packages.</p> |
| type           | character, indicating the type of package to download and install. Will be "source" except on Windows and some macOS builds: see the section on 'Binary packages' for those.   |
| configure.args | <p>(Used only for source installs.) A character vector or a named list. If a character vector with no names is supplied, the elements are concatenated into a single string (separated by a space) and used as the value for the '--configure-args' flag in the call to <code>R CMD INSTALL</code>. If the character vector has names these are assumed to identify values for '--configure-args' for individual packages. This allows one to specify settings for an entire collection of packages which will be used if any of those packages are to be installed. (These settings can therefore be re-used and act as default settings.)</p> <p>A named list can be used also to the same effect, and that allows multi-element character strings for each package which are concatenated to a single string to be used as the value for '--configure-args'.</p>  |
| configure.vars | <p>(Used only for source installs.) Analogous to <code>configure.args</code> for flag '--configure-vars', which is used to set environment variables for the configure run.</p>  |
| clean          | a logical value indicating whether to add the '--clean' flag to the call to <code>R CMD INSTALL</code> . This is sometimes used to perform additional operations at the end of the package installation in addition to removing intermediate files.  |
| Ncpus          | the number of parallel processes to use for a parallel install of more than one source package. Values greater than one are supported if the make command specified by <code>Sys.getenv("MAKE", "make")</code> accepts argument ' <code>-k -j &lt;Ncpus&gt;</code> '.  |
| verbose        | a logical indicating if some "progress report" should be given.  |

|                           |   |
|---------------------------|---|
| <code>libs_only</code>    | a logical value: should the ‘ <code>--libs-only</code> ’ option be used to install only additional sub-architectures for source installs? (See also <code>INSTALL_opts</code> .) This can also be used on Windows to install just the DLL(s) from a binary package, e.g. to add 64-bit DLLs to a 32-bit install.  |
| <code>INSTALL_opts</code> | an optional character vector of additional option(s) to be passed to <code>R CMD INSTALL</code> for a source package install. E.g., <code>c("--html", "--no-multiarch", "--no-test-load")</code> .<br><br>Can also be a named list of character vectors to be used as additional options, with names the respective package names.  |
| <code>quiet</code>        | logical: if true, reduce the amount of output. This is <i>not</i> passed to <code>available.packages()</code> in case that is called, on purpose.   |
| <code>keep_outputs</code> | a logical: if true, keep the outputs from installing source packages in the current working directory, with the names of the output files the package names with ‘.out’ appended (overwriting existing files, possibly from previous installation attempts). Alternatively, a character string giving the directory in which to save the outputs. Ignored when installing from local files. |
| <code>...</code>          | further arguments to be passed to <code>download.file</code> , <code>available.packages</code> , or to the functions for binary installs on macOS and Windows (which accept an argument “lock”: see the section on ‘Locking’).  |

## Details

This is the main function to install packages. It takes a vector of names and a destination library, downloads the packages from the repositories and installs them. (If the library is omitted it defaults to the first directory in `.libPaths()`, with a message if there is more than one.) If `lib` is omitted or is of length one and is not a (group) writable directory, in interactive use the code offers to create a personal library tree (the first element of `Sys.getenv("R_LIBS_USER")`) and install there.

Detection of a writable directory is problematic on Windows: see the ‘Note’ section.

For installs from a repository an attempt is made to install the packages in an order that respects their dependencies. This does assume that all the entries in `lib` are on the default library path for installs (set by environment variable `R_LIBS`).

You are advised to run `update.packages` before `install.packages` to ensure that any already installed dependencies have their latest versions.

## Value

Invisible `NULL`.

## Binary packages

This section applies only to platforms where binary packages are available: Windows and CRAN builds for macOS.

R packages are primarily distributed as *source* packages, but *binary* packages (a packaging up of the installed package) are also supported, and the type most commonly used on Windows and by the CRAN builds for macOS. This function can install either type, either by downloading a file from a repository or from a local file.

Possible values of `type` are (currently) “source”, “mac.binary”, and “win.binary”: the appropriate binary type where supported can also be selected as “binary”.

For a binary install from a repository, the function checks for the availability of a source package on the same repository, and reports if the source package has a later version, or is available but no binary version is. This check can be suppressed by using

```
options(install.packages.check.source = "no")
```

and should be if there is a partial repository containing only binary files.

An alternative (and the current default) is "both" which means 'use binary if available and current, otherwise try source'. The action if there are source packages which are preferred but may contain code which needs to be compiled is controlled by `getOption("install.packages.compile.from.source")`. `type = "both"` will be silently changed to "binary" if either `contriburl` or `available` is specified.

Using packages with `type = "source"` always works provided the package contains no C/C++/Fortran code that needs compilation. Otherwise,

**on Windows**, you will need to have installed the Rtools collection as described in the 'R for Windows FAQ' and you must have the `PATH` environment variable set up as required by Rtools.

For a 32/64-bit installation of R on Windows, a small minority of packages with compiled code need either `INSTALL_opts = "--force-biarch"` or `INSTALL_opts = "--merge-multiarch"` for a source installation. (It is safe to always set the latter when installing from a repository or tarballs, although it will be a little slower.)

When installing a package on Windows, `install.packages` will abort the install if it detects that the package is already installed and is currently in use. In some circumstances (e.g., multiple instances of R running at the same time and sharing a library) it will not detect a problem, but the installation may fail as Windows locks files in use.

**On Unix-alikes**, when the package contains C/C++/Fortran code that needs compilation, suitable compilers and related tools need to be installed. On macOS you need to have installed the 'Command-line tools for Xcode' (see the 'R Installation and Administration' manual) and if needed by the package a Fortran compiler, and have them in your path.

## Locking

There are various options for locking: these differ between source and binary installs.

By default for a source install, the library directory is 'locked' by creating a directory `'00LOCK'` within it. This has two purposes: it prevents any other process installing into that library concurrently, and is used to store any previous version of the package to restore on error. A finer-grained locking is provided by the option `'--pkglock'` which creates a separate lock for each package: this allows enough freedom for parallel installation. Per-package locking is the default when installing a single package, and for multiple packages when `Ncpus > 1L`. Finally locking (and restoration on error) can be suppressed by `'--no-lock'`.

For a macOS binary install, no locking is done by default. Setting argument `lock` to `TRUE` (it defaults to the value of `getOption("install.lock", FALSE)`) will use per-directory locking as described for source installs. For Windows binary install, per-directory locking is used by default (`lock` defaults to the value of `getOption("install.lock", TRUE)`). If the value is `"pkglock"` per-package locking will be used.

If package locking is used on Windows with `libs_only = TRUE` and the installation fails, the package will be restored to its previous state.

Note that it is possible for the package installation to fail so badly that the lock directory is not removed: this inhibits any further installs to the library directory (or for `'--pkglock'`, of the package) until the lock directory is removed manually.

## Parallel installs

Parallel installs are attempted if `pkgs` has length greater than one and `Ncpus > 1`. It makes use of a parallel make, so the make specified (default make) when R was built must be capable of supporting make `-j N`: GNU make, dmake and pmake do, but Solaris make and older FreeBSD make do not: if necessary environment variable `MAKE` can be set for the current session to select a suitable make.

`install.packages` needs to be able to compute all the dependencies of `pkgs` from available, including if one element of `pkgs` depends indirectly on another. This means that if for example you are installing CRAN packages which depend on Bioconductor packages which in turn depend on CRAN packages, `available` needs to cover both CRAN and Bioconductor packages.

## Timeouts

A limit on the elapsed time for each call to R CMD INSTALL (so for source installs) can be set *via* environment variable `_R_INSTALL_PACKAGES_ELAPSED_TIMEOUT_`: in seconds (or in minutes or hours with optional suffix 'm' or 'h', suffix 's' being allowed for the default seconds) with 0 meaning no limit.

For non-parallel installs this is implemented *via* the `timeout` argument of `system2`: for parallel installs *via* the OS's `timeout` command. (The one tested is from GNU **coreutils**, commonly available on Linux but not other Unix-alikes. If no such command is available the timeout request is ignored, with a warning. On Windows, one needs to specify a suitable `timeout` command *via* environment variable `R_TIMEOUT`, because 'c:/Windows/system32/timeout.exe' is not.) For parallel installs a 'Error 124' message from make indicates that timeout occurred.

Timeouts during installation might leave lock directories behind and not restore previous versions.

## Version requirements on source installs

If you are not running an up-to-date version of R you may see a message like

```
package 'RODBC' is not available (for R version 3.5.3)
```

One possibility is that the package is not available in any of the selected repositories; another is that is available but only for current or recent versions of R. For CRAN packages take a look at the package's CRAN page (e.g., <https://cran.r-project.org/package=RODBC>). If that indicates in the 'Depends' field a dependence on a later version of R you will need to look in the 'Old sources' section and select the URL of a version of comparable age to your R. Then you can supply that URL as the first argument of `install.packages()`: you may need to first manually install its dependencies.

For other repositories, using `available.packages(filters = "OS_type") [pkgsname, ]` will show if the package is available for any R version (for your OS).

## Note

**On Unix-alikes:** Some binary distributions of R have `INSTALL` in a separate bundle, e.g. an R-devel RPM. `install.packages` will give an error if called with `type = "source"` on such a system.

Some binary Linux distributions of R can be installed on a machine without the tools needed to install packages: a possible remedy is to do a complete install of R which should bring in all those tools as dependencies.

**On Windows:** `install.packages` tries to detect if you have write permission on the library directories specified, but Windows reports unreliably. If there is only one library directory (the default), R tries to find out by creating a test directory, but even this need not be the whole story: you may have permission to write in a library directory but lack permission to write binary files (such as `.dll` files) there. See the ‘R for Windows FAQ’ for workarounds.

### See Also

`update.packages`, `available.packages`, `download.packages`,  
`installed.packages`, `contrib.url`.

See `download.file` for how to handle proxies and other options to monitor file transfers.

`INSTALL`, `REMOVE`, `remove.packages`, `library`, `.packages`, `read.dcf`

The ‘R Installation and Administration’ manual for how to set up a repository.

### Examples

```
## Not run:
## A Linux example for Fedora's layout of udunits2 headers.
install.packages(c("ncdf4", "RNetCDF"),
  configure.args = c(RNetCDF = "--with-netcdf-include=/usr/include/udunits2"))

## End(Not run)
```

---

`installed.packages` *Find Installed Packages*

---

### Description

Find (or retrieve) details of all packages installed in the specified libraries.

### Usage

```
installed.packages(lib.loc = NULL, priority = NULL,
  noCache = FALSE, fields = NULL,
  subarch = .Platform$r_arch, ...)
```

### Arguments

|                       |   |
|-----------------------|---|
| <code>lib.loc</code>  | character vector describing the location of R library trees to search through, or NULL for all known trees (see <code>.libPaths</code> ).   |
| <code>priority</code> | character vector or NULL (default). If non-null, used to select packages; "high" is equivalent to <code>c("base", "recommended")</code> . To select all packages without an assigned priority use <code>priority = NA_character_</code> . |
| <code>noCache</code>  | Do not use cached information, nor cache it.  |
| <code>fields</code>   | a character vector giving the fields to extract from each package's 'DESCRIPTION' file in addition to the default ones, or NULL (default). Unavailable fields result in NA values.  |
| <code>subarch</code>  | character string or NULL. If non-null and non-empty, used to select packages which are installed for that sub-architecture.   |
| <code>...</code>      | allows unused arguments to be passed down from other functions.   |

## Details

`installed.packages` scans the 'DESCRIPTION' files of each package found along `lib.loc` and returns a matrix of package names, library paths and version numbers.

The information found is cached (by library) for the R session and specified `fields` argument, and updated only if the top-level library directory has been altered, for example by installing or removing a package. If the cached information becomes confused, it can be avoided by specifying `noCache = TRUE`.

## Value

A matrix with one row per package, row names the package names and column names (currently) "Package", "LibPath", "Version", "Priority", "Depends", "Imports", "LinkingTo", "Suggests", "Enhances", "OS\_type", "License" and "Built" (the R version the package was built under). Additional columns can be specified using the `fields` argument.

## Note

This needs to read several files per installed package, which will be slow on Windows and on some network-mounted file systems.

It will be slow when thousands of packages are installed, so do not use it to find out if a named package is installed (use [find.package](#) or [system.file](#)) nor to find out if a package is usable (call [requireNamespace](#) or [require](#) and check the return value) nor to find details of a small number of packages (use [packageDescription](#)).

## See Also

[update.packages](#), [install.packages](#), [INSTALL](#), [REMOVE](#).

## Examples

```
## confine search to .Library for speed
str(ip <- installed.packages(.Library, priority = "high"))
ip[, c(1,3:5)]
plic <- installed.packages(.Library, priority = "high", fields = "License")
## what licenses are there:
table( plic[, "License"] )

## Recommended setup (by many pros):
## Keep packages that come with R (priority="high") and all others separate!
## Consequently, .Library, R's "system" library, shouldn't have any
## non-"high"-priority packages :
pSys <- installed.packages(.Library, priority = NA_character_)
length(pSys) == 0 # TRUE under such a setup
```

## Description

Checks if `method` is the name of a valid / registered S3 method. Alternatively, when `f` and `class` are specified, it is checked if `f` is the name of an S3 generic function and `paste(f, class, sep=" ")` is a valid S3 method.

**Usage**

```
isS3method(method, f, class, envir = parent.frame())
```

**Arguments**

|                     |   |
|---------------------|---|
| <code>method</code> | a character string, typically of the form <code>"fn.class"</code> . If omitted, <code>f</code> and <code>class</code> have to be specified instead. |
| <code>f</code>      | optional character string, typically specifying an S3 generic function. Used, when <code>method</code> is not specified.                            |
| <code>class</code>  | optional character string, typically specifying an S3 class name. Used, when <code>method</code> is not specified.                                  |
| <code>envir</code>  | the <a href="#">environment</a> in which the method and its generic are searched first, as in <a href="#">getS3method()</a> .                       |

**Value**

logical TRUE or FALSE

**See Also**

[methods](#), [getS3method](#).

**Examples**

```
isS3method("t")           # FALSE - it is an S3 generic
isS3method("t.default")   # TRUE
isS3method("t.ts")        # TRUE
isS3method("t.test")      # FALSE
isS3method("t.data.frame") # TRUE
isS3method("t.lm")        # FALSE - not existing
isS3method("t.foo.bar")   # FALSE - not existing

## S3 methods with "4 parts" in their name:
ff <- c("as.list", "as.matrix", "is.na", "row.names", "row.names<-")
for(m in ff) if(isS3method(m)) stop("wrongly declared an S3 method: ", m)
(m4 <- paste(ff, "data.frame", sep="."))
for(m in m4) if(!isS3method(m)) stop("not an S3 method: ", m)
```

---

isS3stdGeneric

---

*Check if a Function Acts as an S3 Generic*

---

**Description**

Determines whether `f` acts as a standard S3-style generic function.

**Usage**

```
isS3stdGeneric(f)
```

**Arguments**

`f` a function object

**Details**

A closure is considered a standard S3 generic if the first expression in its body calls `UseMethod`. Functions which perform operations before calling `UseMethod` will not be considered “standard” S3 generics.

If `f` is currently being traced, i.e., inheriting from class `"traceable"`, the definition of the original untraced version of the function is used instead.

**Value**

If `f` is an S3 generic, a logical containing `TRUE` with the name of the S3 generic (the string passed to `UseMethod`). Otherwise, `FALSE` (unnamed).

---

 LINK

---

*Create Executable Programs on Unix-alikes*

---

**Description**

Front-end for creating executable programs on unix-alikes, i.e., not on Windows.

**Usage**

```
R CMD LINK [options] linkcmd
```

**Arguments**

|                      |   |
|----------------------|---|
| <code>linkcmd</code> | a list of commands to link together suitable object files (include library objects) to create the executable program. |
| <code>options</code> | further options to control the linking, or for obtaining information about usage and version.                         |

**Details**

The linker front-end is useful in particular when linking against the R shared or static library: see the examples.

The actual linking command is constructed by the version of `libtool` installed at `'R_HOME/bin'`.

`R CMD LINK --help` gives usage information.

**Note**

Some binary distributions of R have LINK in a separate bundle, e.g. an R-devel RPM. This is not available on Windows.

**See Also**

[COMPILE](#).

## Examples

```
## Not run: ## examples of front-ends linked against R.
## First a C program
CC=`R CMD config CC`
R CMD LINK $CC -o foo foo.o `R CMD config --ldflags`

## if Fortran code has been compiled into ForFoo.o
FLIBS=`R CMD config FLIBS`
R CMD LINK $CC -o foo foo.o ForFoo.o `R CMD config --ldflags` $FLIBS

## And for a C++ front-end
CXX=`R CMD config CXX`
R CMD COMPILE foo.cc
R CMD LINK $CXX -o foo foo.o `R CMD config --ldflags`

## End(Not run)
```

---

|                 |   |
|-----------------|---|
| localeToCharset | <i>Select a Suitable Encoding Name from a Locale Name</i> |
|-----------------|---|

---

## Description

This functions aims to find a suitable coding for the locale named, by default the current locale, and if it is a UTF-8 locale a suitable single-byte encoding.

## Usage

```
localeToCharset(locale = Sys.getlocale("LC_CTYPE"))
```

## Arguments

locale                      character string naming a locale.

## Details

The operation differs by OS.

**On Windows,** a locale is specified like "English\_United Kingdom.1252". The final component gives the codepage, and this defines the encoding.

**On Unix-alikes:** Locale names are normally like es\_MX.iso88591. If final component indicates an encoding and it is not utf8 we just need to look up the equivalent encoding name. Otherwise, the language (here es) is used to choose a primary or fallback encoding.

In the C locale the answer will be "ASCII".

## Value

A character vector naming an encoding and possibly a fallback single-encoding, NA if unknown.

## Note

The encoding names are those used by libiconv, and ought also to work with glibc but maybe not with commercial Unixen.

**See Also**

[Sys.getlocale](#), [iconv](#).

**Examples**

```
localeToCharset()
```

---

ls.str

*List Objects and their Structure*

---

**Description**

ls.str and lsf.str are variations of [ls](#) applying [str\(\)](#) to each matched name: see section [Value](#).

**Usage**

```
ls.str(pos = -1, name, envir, all.names = FALSE,
       pattern, mode = "any")

lsf.str(pos = -1, envir, ...)

## S3 method for class 'ls_str'
print(x, max.level = 1, give.attr = FALSE, ...,
      digits = max(1, getOption("str")$digits.d))
```

**Arguments**

|           |   |
|-----------|---|
| pos       | integer indicating <a href="#">search</a> path position, or -1 for the current environment.   |
| name      | optional name indicating <a href="#">search</a> path position, see <a href="#">ls</a> .   |
| envir     | environment to use, see <a href="#">ls</a> .  |
| all.names | logical indicating if names which begin with a . are omitted; see <a href="#">ls</a> .  |
| pattern   | a <a href="#">regular expression</a> passed to <a href="#">ls</a> . Only names matching pattern are considered.   |
| max.level | maximal level of nesting which is applied for displaying nested structures, e.g., a list containing sub lists. Default 1: Display only the first nested level.                          |
| give.attr | logical; if TRUE (default), show attributes as sub structures.  |
| mode      | character specifying the <a href="#">mode</a> of objects to consider. Passed to <a href="#">exists</a> and <a href="#">get</a> .  |
| x         | an object of class "ls_str".  |
| ...       | further arguments to pass. lsf.str passes them to ls.str which passes them on to <a href="#">ls</a> . The (non-exported) print method print.ls_str passes them to <a href="#">str</a> . |
| digits    | the number of significant digits to use for printing.   |

**Value**

ls.str and lsf.str return an object of class "ls\_str", basically the character vector of matching names (functions only for lsf.str), similarly to [ls](#), with a print() method that calls [str\(\)](#) on each object.

**Author(s)**

Martin Maechler

**See Also**

[str](#), [summary](#), [args](#).

**Examples**

```
require(stats)

lsf.str()  #- how do the functions look like which I am using?
ls.str(mode = "list")  #- what are the structured objects I have defined?

## create a few objects
example(glm, echo = FALSE)
ll <- as.list(LETTERS)
print(ls.str(), max.level = 0) # don't show details

## which base functions have "file" in their name ?
lsf.str(pos = length(search()), pattern = "file")

## demonstrating that ls.str() works inside functions
## ["browser/debug mode"]:
tt <- function(x, y = 1) { aa <- 7; r <- x + y; ls.str() }
(nms <- sapply(strsplit(capture.output(tt(2)), " *: *"), `[, 1])
stopifnot(nms == c("aa", "r", "x", "y"))
```

---

`maintainer`

*Show Package Maintainer*

---

**Description**

Show the name and email address of the maintainer of an installed package.

**Usage**

```
maintainer(pkg)
```

**Arguments**

`pkg` a character string, the name of an installed package.

**Details**

Accesses the [package description](#) to return the name and email address of the maintainer.

Questions about contributed packages should often be addressed to the package maintainer; questions about base packages should usually be addressed to the R-help or R-devel mailing lists. Bug reports should be submitted using the [bug.report](#) function.

**Value**

A character string giving the name and email address of the maintainer of the package, or `NA_character_` if no such package is installed.

**Author(s)**

David Scott <d.scott@auckland.ac.nz> from code on R-help originally due to Charlie Sharpsteen <source@sharpsteen.net>; multiple corrections by R-core.

**References**

<https://stat.ethz.ch/pipermail/r-help/2010-February/230027.html>

**See Also**

[packageDescription](#), [bug.report](#)

**Examples**

```
maintainer("MASS")
```

---

make.packages.html *Update HTML Package List*

---

**Description**

Re-create the HTML list of packages.

**Usage**

```
make.packages.html(lib.loc = .libPaths(), temp = FALSE,  
                   verbose = TRUE, docdir = R.home("doc"))
```

**Arguments**

|                      |   |
|----------------------|---|
| <code>lib.loc</code> | character vector. List of libraries to be included.   |
| <code>temp</code>    | logical: should the package indices be created in a temporary location for use by the HTTP server?                    |
| <code>verbose</code> | logical. If true, print out a message.  |
| <code>docdir</code>  | If <code>temp</code> is false, directory in whose ‘html’ directory the ‘packages.html’ file is to be created/updated. |

**Details**

This creates the ‘packages.html’ file, either a temporary copy for use by [help.start](#), or the copy in ‘R.home("doc")/html’ (for which you will need write permission).

It can be very slow, as all the package ‘DESCRIPTION’ files in all the library trees are read.

For `temp = TRUE` there is some caching of information, so the file will only be re-created if `lib.loc` or any of the directories it lists have been changed.

**Value**

Invisible logical, with FALSE indicating a failure to create the file, probably due to lack of suitable permissions.

**See Also**

[help.start](#)

**Examples**

```
## Not run:
make.packages.html()
# this can be slow for large numbers of installed packages.

## End(Not run)
```

---

make.socket

*Create a Socket Connection*

---

**Description**

With `server = FALSE` attempts to open a client socket to the specified port and host. With `server = TRUE` the R process listens on the specified port for a connection and then returns a server socket. It is a good idea to use [on.exit](#) to ensure that a socket is closed, as you only get 64 of them.

**Usage**

```
make.socket(host = "localhost", port, fail = TRUE, server = FALSE)
```

**Arguments**

|        |                                 |
|--------|---------------------------------|
| host   | name of remote host             |
| port   | port to connect to/listen on    |
| fail   | failure to connect is an error? |
| server | a server socket?                |

**Value**

An object of class "socket", a list with components:

|        |   |
|--------|---|
| socket | socket number. This is for internal use. On a Unix-alike it is a file descriptor. |
| port   | port number of the connection.  |
| host   | name of remote computer.  |

**Warning**

I don't know if the connecting host name returned when `server = TRUE` can be trusted. I suspect not.

**Author(s)**

Thomas Lumley

## References

Adapted from Luke Tierney's code for XLISP-Stat, in turn based on code from Robbins and Robbins "Practical UNIX Programming".

## See Also

`close.socket`, `read.socket`.

Compiling in support for sockets was optional prior to R 3.3.0: see `capabilities("sockets")` to see if it is available.

## Examples

```
daytime <- function(host = "localhost"){
  a <- make.socket(host, 13)
  on.exit(close.socket(a))
  read.socket(a)
}
## Official time (UTC) from US Naval Observatory
## Not run: daytime("tick.usno.navy.mil")
```

---

|      |                                  |
|------|----------------------------------|
| menu | <i>Menu Interaction Function</i> |
|------|----------------------------------|

---

## Description

`menu` presents the user with a menu of choices labelled from 1 to the number of choices. To exit without choosing an item one can select '0'.

## Usage

```
menu(choices, graphics = FALSE, title = NULL)
```

## Arguments

|                       |   |
|-----------------------|---|
| <code>choices</code>  | a character vector of choices   |
| <code>graphics</code> | a logical indicating whether a graphics menu should be used if available.                   |
| <code>title</code>    | a character string to be used as the title of the menu. <code>NULL</code> is also accepted. |

## Details

If `graphics = TRUE` and a windowing system is available (Windows, macOS or X11 *via* Tcl/Tk) a listbox widget is used, otherwise a text menu. It is an error to use `menu` in a non-interactive session.

Ten or fewer items will be displayed in a single column, more in multiple columns if possible within the current display width.

No title is displayed if `title` is `NULL` or `" "`.

## Value

The number corresponding to the selected item, or 0 if no choice was made.

## References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

## See Also

`select.list`, which is used to implement the graphical menu, and allows multiple selections.

## Examples

```
## Not run:
switch(menu(c("List letters", "List LETTERS")) + 1,
        cat("Nothing done\n"), letters, LETTERS)

## End(Not run)
```

---

methods

*List Methods for S3 Generic Functions or Classes*

---

## Description

List all available methods for a S3 and S4 generic function, or all methods for an S3 or S4 class.

## Usage

```
methods(generic.function, class, all.names = FALSE, dropPath = FALSE)
.S3methods(generic.function, class, envir = parent.frame(),
            all.names = FALSE, dropPath = FALSE)

## S3 method for class 'MethodsFunction'
format(x, byclass = attr(x, "byclass"), ...)
## S3 method for class 'MethodsFunction'
print(x, byclass = attr(x, "byclass"), ...)
```

## Arguments

|                               |   |
|-------------------------------|---|
| <code>generic.function</code> | a generic function, or a character string naming a generic function.  |
| <code>class</code>            | a symbol or character string naming a class: only used if <code>generic.function</code> is not supplied.  |
| <code>envir</code>            | the environment in which to look for the definition of the generic function, when the generic function is passed as a character string.   |
| <code>all.names</code>        | a <a href="#">logical</a> indicating if all object names are returned. When <code>FALSE</code> as by default, names beginning with a <code>'.'</code> are omitted.  |
| <code>dropPath</code>         | a <a href="#">logical</a> indicating if the <code>search()</code> path, apart from <code>.GlobalEnv</code> and <code>package:base</code> (i.e., <code>baseenv()</code> ), should be skipped when searching for method definitions. The default <code>FALSE</code> is back compatible and typically desired for <code>print()</code> ing, with or without asterisk; <code>dropPath=TRUE</code> has been hard coded in R 4.3.0 and is faster for non-small <code>search()</code> paths. |

|                      |  |
|----------------------|--|
| <code>x</code>       | typically the result of <code>methods(...)</code> , an R object of S3 class "MethodsFunction", see 'Value' below.                      |
| <code>byclass</code> | an optional <a href="#">logical</a> allowing to override the "byclass" attribute determining how the result is printed, see 'Details'. |
| <code>...</code>     | potentially further arguments passed to and from <code>methods</code> ; unused currently.  |

### Details

`methods()` finds S3 and S4 methods associated with either the `generic.function` or `class` argument. Methods found are those provided by all loaded namespaces via registration, see [UseMethod](#); normally, this includes all packages on the current `search()` path. `.S3methods()` finds only S3 methods, `.S4methods()` finds only S4 methods.

When invoked with the `generic.function` argument, the "byclass" attribute (see Details) is FALSE, and the `print` method by default displays the signatures (full names) of S3 and S4 methods. S3 methods are printed by pasting the generic function and class together, separated by a '.', as `generic.class`. The S3 method name is followed by an asterisk \* if the method definition is not exported from the package namespace in which the method is defined. S4 method signatures are printed as `generic, class-method`; S4 allows for multiple dispatch, so there may be several classes in the signature `generic, A, B-method`.

When invoked with the `class` argument, "byclass" is TRUE, and the `print` method by default displays the names of the generic functions associated with the class, `generic`.

The source code for all functions is available. For S3 functions exported from the namespace, enter the method at the command line as `generic.class`. For S3 functions not exported from the namespace, see `getAnywhere` or `getS3method`. For S4 methods, see `getMethod`.

Help is available for each method, in addition to each generic. For interactive help, use the documentation shortcut `?`  with the name of the generic and tab completion, `? "generic<tab>"` to select the method for which help is desired.

The S3 functions listed are those which *are named like methods* and may not actually be methods (known exceptions are discarded in the code).

### Value

An object of class "MethodsFunction", a character vector of method names with "byclass" and "info" attributes. The "byclass" attribute is a [logical](#) indicating if the results were obtained with argument `class` defined. The "info" attribute is a data frame with columns:

**generic** [character](#) vector of the names of the generic.

**visible** `logical()`, is the method "visible" to the user? When true, it typically is exported from the namespace of the package in which it is defined, and the package is [attach\(\)](#)ed to the [search\(\)](#) path.

**isS4** `logical()`, true when the method is an S4 method.

**from** a [factor](#), the location or package name where the method was found.

### Note

The original `methods` function was written by Martin Maechler.

 mirrorAdmin

*Managing Repository Mirrors*

---

**Description**

Functions helping to maintain CRAN, some of them may also be useful for administrators of other repository networks.

**Usage**

```
mirror2html(mirrors = NULL, file = "mirrors.html",
  head = "mirrors-head.html", foot = "mirrors-foot.html")
checkCRAN(method)
```

**Arguments**

|         |  |
|---------|--|
| mirrors | A data frame, by default the CRAN list of mirrors is used. |
| file    | A <a href="#">connection</a> or a character string.        |

|        |   |
|--------|---|
| head   | Name of optional header file.                     |
| foot   | Name of optional footer file.                     |
| method | Download method, see <code>download.file</code> . |

### Details

`mirror2html` creates the HTML file for the CRAN list of mirrors and invisibly returns the HTML text.

`checkCRAN` performs a sanity checks on all CRAN mirrors.

---

|                         |  |
|-------------------------|--|
| <code>modifyList</code> | <i>Recursively Modify Elements of a List</i> |
|-------------------------|--|

---

### Description

Modifies a possibly nested list recursively by changing a subset of elements at each level to match a second list.

### Usage

```
modifyList(x, val, keep.null = FALSE)
```

### Arguments

|                        |  |
|------------------------|--|
| <code>x</code>         | A named <code>list</code> , possibly empty.  |
| <code>val</code>       | A named list with components to replace corresponding components in <code>x</code> or add new components.  |
| <code>keep.null</code> | If <code>TRUE</code> , <code>NULL</code> elements in <code>val</code> become <code>NULL</code> elements in <code>x</code> . Otherwise, the corresponding element, if present, is deleted from <code>x</code> . |

### Value

A modified version of `x`, with the modifications determined as follows (here, list elements are identified by their names). Elements in `val` which are missing from `x` are added to `x`. For elements that are common to both but are not both lists themselves, the component in `x` is replaced (or possibly deleted, depending on the value of `keep.null`) by the one in `val`. For common elements that are in both lists, `x[[name]]` is replaced by `modifyList(x[[name]], val[[name]])`.

### Author(s)

Deepayan Sarkar <Deepayan.Sarkar@R-project.org>

### Examples

```
foo <- list(a = 1, b = list(c = "a", d = FALSE))
bar <- modifyList(foo, list(e = 2, b = list(d = TRUE)))
str(foo)
str(bar)
```

**Description**

Build and query the news data base for R or add-on packages.

**Usage**

```
news(query, package = "R", lib.loc = NULL, format = NULL,
      reader = NULL, db = NULL)

## S3 method for class 'news_db'
print(x, doBrowse = interactive(),
      browser = getOption("browser"), ...)
```

**Arguments**

|          |  |
|----------|--|
| query    | an optional expression for selecting news entries.   |
| package  | a character string giving the name of an installed add-on package, or "R" or "R-3" or "R-2".   |
| lib.loc  | a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known.   |
| format   | Not yet used.  |
| reader   | Not yet used.  |
| db, x    | a news db obtained from <code>news()</code> .  |
| doBrowse | logical specifying that the news should be opened in the browser (by <a href="#">browseURL</a> , accessible as via <a href="#">help.start</a> ) instead of printed to the console. |
| browser  | the browser to be used, see <a href="#">browseURL</a> .  |
| ...      | potentially further arguments passed to <code>print()</code> .   |

**Details**

If `package` is "R" (default), a news db is built with the news since the 4.0.0 release of R, corresponding to the 'NEWS' file in the `R.home("doc")` directory. "R-3" or "R-2" give the news for R 3.x.y or R 2.x.y respectively. Otherwise, if the given add-on package can be found in the given libraries, it is attempted to read its news in structured form from files 'inst/NEWS.Rd', 'NEWS.md' (since R version 3.6.0, needs packages **commonmark** and **xml2** to be available), 'NEWS' or 'inst/NEWS' (in that order). See section 'NEWS Formats' for the file specifications.

Using `query`, one can select news entries from the db. If missing or NULL, the complete db is returned. Otherwise, `query` should be an expression involving (a subset of) the variables `Version`, `Category`, `Date` and `Text`, and when evaluated within the db returning a logical vector with length the number of entries in the db. The entries for which evaluation gave TRUE are selected. When evaluating, `Version` and `Date` are coerced to [numeric\\_version](#) and [Date](#) objects, respectively, so that the comparison operators for these classes can be employed.

**Value**

A data frame inheriting from class "news\_db", with character variables `Version`, `Category`, `Date`, `Text` and `HTML`, where the last two each contain the entry texts read (in plain-text and HTML format, respectively), and the other variables may be NA if they were missing or could not be determined. The data frame has `attributes` "package" (and "subset" if the query lead to proper subsetting).

**NEWS Formats**

**‘inst/NEWS.Rd’:** File ‘inst/NEWS.Rd’ should be an Rd file given the entries as Rd `\itemize` lists, grouped according to version using `\section` elements. Section titles start with a suitable prefix followed by a space and the version number, and optionally end with a (parenthesized) ISO 8601 (%Y-%m-%d, see `strptime`) format date (optionally including a note), for example:

```
\section{Changes in version 2.0 (2020-02-02, <note>)}{
  \itemize{
    \item ....
  }
}
```

The entries can be further grouped according to categories using `\subsection` elements named as the categories. The ‘NEWS.Rd’ file is assumed to be UTF-8-encoded (but an included `\encoding` specification takes precedence).

**‘NEWS.md’:** File ‘NEWS.md’ should contain the news in Markdown (following the Common-Mark (<https://commonmark.org/>) specification), with the primary heading level giving the version number after a prefix followed by a space, and optionally followed by a space and a parenthesized ISO 8601 format date. Where available, secondary headings are taken to indicate categories. To accommodate for common practice, news entries are only split down to the category level.

**‘NEWS’:** The plain text ‘NEWS’ files in add-on packages use a variety of different formats; the default news reader should be capable to extract individual news entries from a majority of packages from the standard repositories, which use (slight variations of) the following format:

- Entries are grouped according to version, with version header “Changes in version” at the beginning of a line, followed by a version number, optionally followed by an ISO 8601 format date, possibly parenthesized.
- Entries may be grouped according to category, with a category header (different from a version header) starting at the beginning of a line.
- Entries are written as itemize-type lists, using one of ‘o’, ‘\*’, ‘-’ or ‘+’ as item tag. Entries must be indented, and ideally use a common indentation for the item texts.

Package **tools** provides an (internal) utility function `news2Rd` to convert plain text ‘NEWS’ files to Rd. For ‘NEWS’ files in a format which can successfully be handled by the default reader, package maintainers can use `tools::news2Rd(dir, "NEWS.Rd")`, possibly with additional argument `codify = TRUE`, with `dir` a character string specifying the path to a package’s root directory. Upon success, the ‘NEWS.Rd’ file can further be improved and then be moved to the ‘inst’ subdirectory of the package source directory.

Additional formats and readers may be supported in the future.

## Examples

```
## Build a db of all R news entries.
db <- news()

## Bug fixes with PR number in 4.0.0.
db4 <- news(Version == "4.0.0" & grepl("^BUG", Category) & grepl("PR#", Text),
            db = db)
nrow(db4)

## print db4 to show in an HTML browser.

## News from a date range ('Matrix' is there in a regular R installation):
if(length(iM <- find.package("Matrix", quiet = TRUE)) && nzchar(iM)) {
  dM <- news(package="Matrix")
  stopifnot(identical(dM, news(db=dM)))
  dM2014 <- news("2014-01-01" <= Date & Date <= "2014-12-31", db = dM)
  stopifnot(paste0("1.1-", 2:4) %in% dM2014[, "Version"])
}

## Which categories have been in use? % R-core maybe should standardize a bit more
sort(table(db[, "Category"]), decreasing = TRUE)
## Entries with version >= 4.0.0
table(news(Version >= "4.0.0", db = db)$Version)

## do the same for R 3.x.y, more slowly
db3 <- news(package = "R-3")
sort(table(db3[, "Category"]), decreasing = TRUE)
## Entries with version >= 3.6.0
table(news(Version >= "3.6.0", db = db3)$Version)
```

---

nsl

---

*Look up the IP Address by Hostname (on Unix-alikes)*

---

## Description

Interface to the system `gethostbyname`, currently available only on unix-alikes, i.e., not on Windows.

## Usage

```
nsl(hostname)
```

## Arguments

`hostname`      the name of the host.

## Details

This was included as a test of internet connectivity, to fail if the node running R is not connected. It will also return NULL if BSD networking is not supported, including the header file `'arpa/inet.h'`.

This function is not available on Windows.

Value

The IP address, as a character string, or NULL if the call fails.

Examples

```
if(.Platform$OS.type == "unix") # includes Mac
  print( nsl("www.r-project.org") )
```

---

|             |   |
|-------------|---|
| object.size | <i>Report the Space Allocated for an Object</i> |
|-------------|---|

---

Description

Provides an estimate of the memory that is being used to store an R object.

Usage

```
object.size(x)

## S3 method for class 'object_size'
format(x, units = "b", standard = "auto", digits = 1L, ...)
## S3 method for class 'object_size'
print(x, quote = FALSE, units = "b", standard = "auto",
      digits = 1L, ...)
```

Arguments

|          |   |
|----------|---|
| x        | an R object.  |
| quote    | logical, indicating whether or not the result should be printed with surrounding quotes.  |
| units    | <p>the units to be used in formatting and printing the size. Allowed values for the different standards are</p> <p>standard = "legacy": "b", "Kb", "Mb", "Gb", "Tb", "Pb", "B", "KB", "MB", "GB", "TB" and "PB".</p> <p>standard = "IEC": "B", "KiB", "MiB", "GiB", "TiB", "PiB", "EiB", "ZiB" and "YiB".</p> <p>standard = "SI": "B", "kB", "MB", "GB", "TB", "PB", "EB", "ZB", "YB", "RB", and "QB".</p> <p>For all standards, units = "auto" is also allowed. If standard = "auto", any of the "legacy" and IEC units are allowed. See ‘Formatting and printing object sizes’ for details.</p> |
| standard | the byte-size unit standard to be used. A character string, possibly abbreviated from "legacy", "IEC", "SI" and "auto". See ‘Formatting and printing object sizes’ for details.   |
| digits   | the number of digits after the decimal point, passed to <a href="#">round</a> .   |
| ...      | arguments to be passed to or from other methods.  |

Details

Exactly which parts of the memory allocation should be attributed to which object is not clear-cut. This function merely provides a rough indication: it should be reasonably accurate for atomic vectors, but does not detect if elements of a list are shared, for example. (Sharing amongst elements of a character vector is taken into account, but not that between character vectors in a single object.)

The calculation is of the size of the object, and excludes the space needed to store its name in the symbol table.

Associated space (e.g., the environment of a function and what the pointer in a `EXTPTRSXP` points to) is not included in the calculation.

Object sizes are larger on 64-bit builds than 32-bit ones, but will very likely be the same on different platforms with the same word length and pointer size.

Sizes of objects using a compact internal representation may be over-estimated.

Value

An object of class `"object_size"` with a length-one double value, an estimate of the memory allocation attributable to the object in bytes.

Formatting and printing object sizes

Object sizes can be formatted using byte-size units from R's legacy standard, the IEC standard, or the SI standard. As illustrated by below tables, the legacy and IEC standards use *binary* units (multiples of 1024), whereas the SI standard uses *decimal* units (multiples of 1000).

For methods `format` and `print`, argument `standard` specifies which standard to use and argument `units` specifies which byte-size unit to use. `units = "auto"` chooses the largest units in which the result is one or more (before rounding). Byte sizes are rounded to `digits` decimal places. `standard = "auto"` chooses the standard based on `units`, if possible, otherwise, the legacy standard is used.

Summary of R's legacy and IEC units:

| object size | legacy  | IEC   |
|-------------|---------|-------|
| 1           | 1 bytes | 1 B   |
| 1024        | 1 Kb    | 1 KiB |
| 1024^2      | 1 Mb    | 1 MiB |
| 1024^3      | 1 Gb    | 1 GiB |
| 1024^4      | 1 Tb    | 1 TiB |
| 1024^5      | 1 Pb    | 1 PiB |
| 1024^6      |         | 1 EiB |
| 1024^7      |         | 1 ZiB |
| 1024^8      |         | 1 YiB |

Summary of SI units:

| object size | SI   |
|-------------|------|
| 1           | 1 B  |
| 1000        | 1 kB |
| 1000^2      | 1 MB |
| 1000^3      | 1 GB |
| 1000^4      | 1 TB |

|         |      |
|---------|------|
| 1000^5  | 1 PB |
| 1000^6  | 1 EB |
| 1000^7  | 1 ZB |
| 1000^8  | 1 YB |
| 1000^9  | 1 RB |
| 1000^10 | 1 QB |

**Author(s)**

R Core; Henrik Bengtsson for the non-legacy standards.

**References**

The wikipedia page, [https://en.wikipedia.org/wiki/Binary\\_prefix](https://en.wikipedia.org/wiki/Binary_prefix), is extensive on the different standards, usages and their history.

**See Also**

[Memory-limits](#) for the design limitations on object size.

**Examples**

```
object.size(letters)
object.size(ls)
format(object.size(library), units = "auto")

sl <- object.size(rep(letters, 1000))

print(sl)                                ## 209288 bytes
print(sl, units = "auto")                 ## 204.4 Kb
print(sl, units = "auto", standard = "IEC") ## 204.4 KiB
print(sl, units = "auto", standard = "SI")  ## 209.3 kB

(fsl <- sapply(c("Kb", "KB", "KiB"),
  function(u) format(sl, units = u)))
stopifnot(identical( ## assert that all three are the same :
  unique(substr(as.vector(fsl), 1,5)),
  format(round(as.vector(sl)/1024, 1))))

## find the 10 largest objects in the base package
z <- sapply(ls("package:base"), function(x)
  object.size(get(x, envir = baseenv())))
if(interactive()) {
  as.matrix(rev(sort(z))[1:10])
} else # (more constant over time):
  names(rev(sort(z))[1:10])
```

## Description

`package.skeleton` automates some of the setup for a new source package. It creates directories, saves functions, data, and R code files to appropriate places, and creates skeleton help files and a ‘Read-and-delete-me’ file describing further steps in packaging.

## Usage

```
package.skeleton(name = "anRpackage", list,
                 environment = .GlobalEnv,
                 path = ".", force = FALSE,
                 code_files = character(), encoding = "unknown")
```

## Arguments

|                          |   |
|--------------------------|---|
| <code>name</code>        | character string: the package name and directory name for your package. Must be a valid package name.   |
| <code>list</code>        | character vector naming the R objects to put in the package. Usually, at most one of <code>list</code> , <code>environment</code> , or <code>code_files</code> will be supplied. See ‘Details’.                               |
| <code>environment</code> | an environment where objects are looked for. See ‘Details’.   |
| <code>path</code>        | path to put the package directory in.   |
| <code>force</code>       | If <code>FALSE</code> will not overwrite an existing directory.   |
| <code>code_files</code>  | a character vector with the paths to R code files to build the package around. See ‘Details’.   |
| <code>encoding</code>    | optionally a <a href="#">character</a> string with an encoding for an optional ‘Encoding:’ line in ‘DESCRIPTION’ when non-ASCII characters will be used; typically one of "latin1", "latin2", or "UTF-8"; see the WRE manual. |

## Details

The arguments `list`, `environment`, and `code_files` provide alternative ways to initialize the package. If `code_files` is supplied, the files so named will be sourced to form the environment, then used to generate the package skeleton. Otherwise `list` defaults to the objects in `environment` (including those whose names start with `.`), but can be supplied to select a subset of the objects in that environment.

Stubs of help files are generated for functions, data objects, and S4 classes and methods, using the [prompt](#), [promptClass](#), and [promptMethods](#) functions. If an object from another package is intended to be imported and re-exported without changes, the [promptImport](#) function should be used after `package.skeleton` to generate a simple help file linking to the original one.

The package sources are placed in subdirectory `name` of `path`. If `code_files` is supplied, these files are copied; otherwise, objects will be dumped into individual source files. The file names in `code_files` should have suffix `".R"` and be in the current working directory.

The filenames created for source and documentation try to be valid for all OSes known to run R. Invalid characters are replaced by `_`, invalid names are preceded by `zz`, names are converted to lower case (to avoid case collisions on case-insensitive file systems) and finally the converted names are made unique by [make.unique](#) (`sep = "_"`). This can be done for code and help files but not data files (which are looked for by name). Also, the code and help files should have names starting with an ASCII letter or digit, and this is checked and if necessary `z` prepended.

Functions with names starting with a dot are placed in file `‘R/name-internal.R’`.

When you are done, delete the ‘Read-and-delete-me’ file, as it should not be distributed.

**Value**

Used for its side-effects.

**References**

Read the ‘Writing R Extensions’ manual for more details.

Once you have created a *source* package you need to install it: see the ‘R Installation and Administration’ manual, [INSTALL](#) and [install.packages](#).

**See Also**

[prompt](#), [promptClass](#), and [promptMethods](#).

[package\\_native\\_routine\\_registration\\_skeleton](#) for helping in preparing packages with compiled code.

**Examples**

```
require(stats)
## two functions and two "data sets" :
f <- function(x, y) x+y
g <- function(x, y) x-y
d <- data.frame(a = 1, b = 2)
e <- rnorm(1000)

package.skeleton(list = c("f", "g", "d", "e"), name = "mypkg")
```

---

packageDescription *Package Description*

---

**Description**

Parses and returns the ‘DESCRIPTION’ file of a package as a "packageDescription".

Utility functions return (transformed) parts of that.

**Usage**

```
packageDescription(pkg, lib.loc = NULL, fields = NULL,
                  drop = TRUE, encoding = "")
packageVersion(pkg, lib.loc = NULL)
packageDate(pkg, lib.loc = NULL,
            date.fields = c("Date", "Packaged", "Date/Publication", "Built"),
            tryFormats = c("%Y-%m-%d", "%Y/%m/%d", "%D", "%m/%d/%Y"),
            desc = packageDescription(pkg, lib.loc=lib.loc, fields=date.fields))
asDateBuilt(built)
```

**Arguments**

|                          |   |
|--------------------------|---|
| <code>pkg</code>         | a character string with the package name.   |
| <code>lib.loc</code>     | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. If the default is used, the loaded packages and namespaces are searched before the libraries.       |
| <code>fields</code>      | a character vector giving the tags of fields to return (if other fields occur in the file they are ignored).  |
| <code>drop</code>        | If <code>TRUE</code> and the length of <code>fields</code> is 1, then a single character string with the value of the respective field is returned instead of an object of class <code>"packageDescription"</code> .  |
| <code>encoding</code>    | If there is an <code>Encoding</code> field, to what encoding should re-encoding be attempted? If <code>NA</code> , no re-encoding. The other values are as used by <code>iconv</code> , so the default <code>" "</code> indicates the encoding of the current locale. |
| <code>date.fields</code> | character vector of field tags to be tried. The first for which <code>as.Date(.)</code> is not <code>NA</code> will be returned. (Partly experimental, see <i>Note</i> .)   |
| <code>tryFormats</code>  | date formats to try, see <code>as.Date.character()</code> .   |
| <code>desc</code>        | optionally, a named <code>list</code> with components named from <code>date.fields</code> ; where the default is fine, a complete <code>packageDescription()</code> maybe specified as well.  |
| <code>built</code>       | for <code>asDateBuilt()</code> , a <code>character</code> string as from <code>packageDescription(*, fields="Built")</code> .   |

**Details**

A package will not be ‘found’ unless it has a ‘DESCRIPTION’ file which contains a valid `Version` field. Different warnings are given when no package directory is found and when there is a suitable directory but no valid ‘DESCRIPTION’ file.

An `attached` environment named to look like a package (e.g., `package:utils2`) will be ignored.

`packageVersion()` is a convenience shortcut, allowing things like `if (packageVersion("MASS") < "7.3") { do.things }`.

For `packageDate()`, if `desc` is valid, both `pkg` and `lib.loc` are not made use of.

**Value**

If a ‘DESCRIPTION’ file for the given package is found and can successfully be read, `packageDescription` returns an object of class `"packageDescription"`, which is a named list with the values of the (given) fields as elements and the tags as names, unless `drop = TRUE`.

If parsing the ‘DESCRIPTION’ file was not successful, it returns a named list of `NA`s with the field tags as names if `fields` is not null, and `NA` otherwise.

`packageVersion()` returns a (length-one) object of class `"package_version"`.

`packageDate()` will return a `"Date"` object from `as.Date()` or `NA`.

`asDateBuilt(built)` returns a `"Date"` object or signals an error if `built` is invalid.

**Note**

The default behavior of `packageDate()`, notably for `date.fields`, is somewhat experimental and may change.

**See Also**

**Examples**

```
packageDescription("stats")
packageDescription("stats", fields = c("Package", "Version"))

packageDescription("stats", fields = "Version")
packageDescription("stats", fields = "Version", drop = FALSE)

if(requireNamespace("MASS") && packageVersion("MASS") < "7.3.29")
  message("you need to update 'MASS'")

pu <- packageDate("utils")
str(pu)
stopifnot(identical(pu, packageDate(desc = packageDescription("utils"))),
           identical(pu, packageDate("stats"))) # as "utils" and "stats" are
                                                # both 'base R' and "Built" at same time
```

---

packageName

*Find Package Associated with an Environment*

---

**Description**

Many environments are associated with a package; this function attempts to determine that package.

**Usage**

```
packageName(env = parent.frame())
```

**Arguments**

env                      The environment whose name we seek.

**Details**

Environment `env` would be associated with a package if `topenv(env)` is the namespace environment for that package. Thus when `env` is the environment associated with functions inside a package, or local functions defined within them, `packageName` will normally return the package name.

Not all environments are associated with a package: for example, the global environment, or the evaluation frames of functions defined there. `packageName` will return `NULL` in these cases.

**Value**

A length one character vector containing the name of the package, or `NULL` if there is no name.

**See Also**

[getPackageName](#) is a more elaborate function that can construct a name if none is found.

## Examples

```
packageName()
packageName(environment(mean))
```

---

packageStatus

*Package Management Tools*

---

## Description

Summarize information about installed packages and packages available at various repositories, and automatically upgrade outdated packages.

## Usage

```
packageStatus(lib.loc = NULL, repositories = NULL, method,
              type = getOption("pkgType"), ...)

## S3 method for class 'packageStatus'
summary(object, ...)

## S3 method for class 'packageStatus'
update(object, lib.loc = levels(object$inst$LibPath),
        repositories = levels(object$avail$Repository), ...)

## S3 method for class 'packageStatus'
upgrade(object, ask = TRUE, ...)
```

## Arguments

|                           |   |
|---------------------------|---|
| <code>lib.loc</code>      | a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to all libraries currently known.   |
| <code>repositories</code> | a character vector of URLs describing the location of R package repositories on the Internet or on the local machine. These should be full paths to the appropriate ‘contrib’ sections of the repositories. The default (NULL) derives URLs from <a href="#">option</a> "repos" and type. |
| <code>method</code>       | download method, see <a href="#">download.file</a> .  |
| <code>type</code>         | type of package distribution: see <a href="#">install.packages</a> .  |
| <code>object</code>       | an object of class "packageStatus" as returned by packageStatus.  |
| <code>ask</code>          | if TRUE, the user is prompted which packages should be upgraded and which not.  |
| <code>...</code>          | for packageStatus: arguments to be passed to <a href="#">available.packages</a> and <a href="#">installed.packages</a> .<br>for the upgrade method, arguments to be passed to <a href="#">install.packages</a><br>for other methods: currently not used.                                  |

## Details

There are `print` and `summary` methods for the "packageStatus" objects: the `print` method gives a brief tabular summary and the `summary` method prints the results.

The `update` method updates the "packageStatus" object. The `upgrade` method is similar to [update.packages](#): it offers to install the current versions of those packages which are not currently up-to-date.

## Value

An object of class "packageStatus". This is a list with two components

|                    |  |
|--------------------|--|
| <code>inst</code>  | a data frame with columns as the <i>matrix</i> returned by <a href="#">installed.packages</a> plus "Status", a factor with levels <code>c("ok", "upgrade", "unavailable")</code> . Only the newest version of each package is reported, in the first repository in which it appears. |
| <code>avail</code> | a data frame with columns as the <i>matrix</i> returned by <a href="#">available.packages</a> plus "Status", a factor with levels <code>c("installed", "not installed")</code> .   |

For the `summary` method the result is also of class "summary.packageStatus" with additional components

|                    |   |
|--------------------|---|
| <code>Libs</code>  | a list with one element for each library    |
| <code>Repos</code> | a list with one element for each repository |

with the elements being lists of character vectors of package name for each status.

## See Also

[installed.packages](#), [available.packages](#)

## Examples

```
x <- packageStatus(repositories = contrib.url(findCRANmirror("web")))
print(x)
summary(x)

## Not run:
upgrade(x)
x <- update(x)
print(x)

## End(Not run)
```

---

page

*Invoke a Pager on an R Object*

---

### Description

Displays a representation of the object named by `x` in a pager *via* `file.show`.

### Usage

```
page(x, method = c("dput", "print"), ...)
```

### Arguments

|                     |  |
|---------------------|--|
| <code>x</code>      | An R object, or a character string naming an object.   |
| <code>method</code> | The default method is to dump the object <i>via</i> <code>dput</code> . An alternative is to use <code>print</code> and capture the output to be shown in the pager. Can be abbreviated. |
| <code>...</code>    | additional arguments for <code>dput</code> , <code>print</code> or <code>file.show</code> (such as <code>title</code> ).   |

### Details

If `x` is a length-one character vector, it is used as the name of an object to look up in the environment from which `page` is called. All other objects are displayed directly.

A default value of `title` is passed to `file.show` if one is not supplied in `...`

### See Also

`file.show`, `edit`, `fix`.

To go to a new page when graphing, see `frame`.

### Examples

```
## Not run: ## four ways to look at the code of 'page'
page(page)           # as an object
page("page")        # a character string
v <- "page"; page(v)  # a length-one character vector
page(utils::page)    # a call

## End(Not run)
```

---

person

*Persons*

---

### Description

A class and utility methods for holding information about persons like name and email address.

**Usage**

```

person(given = NULL, family = NULL, middle = NULL,
       email = NULL, role = NULL, comment = NULL,
       first = NULL, last = NULL)

as.person(x)
## Default S3 method:
as.person(x)

## S3 method for class 'person'
format(x,
       include = c("given", "family", "email", "role", "comment"),
       braces = list(given = "", family = "", email = c("<", ">"),
                     role = c("[", "]"), comment = c("(", ")")),
       collapse = list(given = " ", family = " ", email = ", ",
                       role = ", ", comment = ", "),
       ...,
       style = c("text", "R"))

## S3 method for class 'person'
toBibtex(object, escape = FALSE, ...)

```

**Arguments**

|                       |  |
|-----------------------|--|
| <code>given</code>    | a character vector with the <i>given</i> names, or a list thereof.   |
| <code>family</code>   | a character string with the <i>family</i> name, or a list thereof.   |
| <code>middle</code>   | a character string with the collapsed middle name(s). Deprecated, see <b>Details</b> .   |
| <code>email</code>    | a character string (or vector) giving an e-mail address (each), or a list thereof.   |
| <code>role</code>     | a character vector specifying the role(s) of the person (see <b>Details</b> ), or a list thereof.  |
| <code>comment</code>  | a character string (or vector) providing comments, or a list thereof.  |
| <code>first</code>    | a character string giving the first name. Deprecated, see <b>Details</b> .   |
| <code>last</code>     | a character string giving the last name. Deprecated, see <b>Details</b> .  |
| <code>x</code>        | an object for the <code>as.person</code> generic; a character string for the <code>as.person</code> default method; an object of class "person" otherwise. |
| <code>include</code>  | a character vector giving the fields to be included when formatting.   |
| <code>braces</code>   | a list of characters (see <b>Details</b> ).  |
| <code>collapse</code> | a list of characters (see <b>Details</b> ).  |
| <code>...</code>      | currently not used.  |
| <code>style</code>    | a character string specifying the print style, with "R" yielding formatting as R code.   |
| <code>object</code>   | an R object inhering from class "person".  |
| <code>escape</code>   | a logical indicating whether non-ASCII characters should be translated to LaTeX escape sequences.  |

## Details

Objects of class "person" can hold information about an arbitrary positive number of persons. These can be obtained by one call to `person()` with list arguments, or by first creating objects representing single persons and combining these via `c()`.

The `format()` method collapses information about persons into character vectors (one string for each person): the fields in `include` are selected, each collapsed to a string using the respective element of `collapse` and subsequently "embraced" using the respective element of `braces`, and finally collapsed into one string separated by white space. If `braces` and/or `collapse` do not specify characters for all fields, the defaults shown in the usage are imputed. If `collapse` is `FALSE` or `NA` the corresponding field is not collapsed but only the first element is used. The `print()` method calls the `format()` method and prints the result, the `toBibtex()` method creates a suitable BibTeX representation.

Person objects can be subscripted by fields (using `$`) or by position (using `[]`).

`as.person()` is a generic function. Its default method tries to reverse the default person formatting, and can also handle formatted person entries collapsed by comma or "and" (with appropriate white space).

Personal names are rather tricky, e.g., [https://en.wikipedia.org/wiki/Personal\\_name](https://en.wikipedia.org/wiki/Personal_name).

The current implementation (starting from R 2.12.0) of the "person" class uses the notions of *given* (including middle names) and *family* names, as specified by `given` and `family` respectively. Earlier versions used a scheme based on first, middle and last names, as appropriate for most of Western culture where the given name precedes the family name, but not universal, as some other cultures place it after the family name, or use no family name. To smooth the transition to the new scheme, arguments `first`, `middle` and `last` are still supported, but their use is deprecated and they must not be given in combination with the corresponding new style arguments. For persons which are not natural persons (e.g., institutions, companies, etc.) it is appropriate to use `given` (but not `family`) for the name, e.g., `person("R Core Team", role = "aut")`.

The new scheme also adds the possibility of specifying *roles* based on a subset of the MARC Code List for Relators (<https://www.loc.gov/marc/relators/relaterm.html>). When giving the roles of persons in the context of authoring R packages, the following usage is suggested.

"aut" (Author) Use for full authors who have made substantial contributions to the package and should show up in the package citation.

"com" (Compiler) Use for persons who collected code (potentially in other languages) but did not make further substantial contributions to the package.

"cph" (Copyright holder) Use for all copyright holders. This is a legal concept so should use the legal name of an institution or corporate body. Note that authors which are 'natural persons' are by default copyright holders and so do not need to be given this role.

"cre" (Creator) Use for the package maintainer.

"ctb" (Contributor) Use for authors who have made smaller contributions (such as code patches etc.) but should not show up in the package citation.

"ctr" (Contractor) Use for authors who have been contracted to write (parts of) the package and hence do not own intellectual property.

"dtr" (Data contributor) Use for persons who contributed data sets for the package.

"fnd" (Funder) Use for persons or organizations that furnished financial support for the development of the package.

"rev" (Reviewer) Use for persons or organizations responsible for reviewing (parts of) the package.

"ths" (Thesis advisor) If the package is part of a thesis, use for the thesis advisor.

"trl" (Translator) If the R code is a translation from another language (typically S), use for the translator to R.

In the old scheme, person objects were used for single persons, and a separate "personList" class with corresponding creator `personList()` for collections of these. The new scheme employs a single class for information about an arbitrary positive number of persons, eliminating the need for the `personList` mechanism.

The `comment` field can be used for "arbitrary" additional information about persons. Elements named "ORCID" will be taken to give ORCID identifiers (see <https://orcid.org/> for more information), and be displayed as the corresponding URIs by the `print()` and `format()` methods (see **Examples** below).

Where more than one entity is given a "cph" role, the `comment` field should be used to delimit who owns the copyright to what parts of the package.

## Value

`person()` and `as.person()` return objects of class "person".

## See Also

[citation](#)

## Examples

```
## Create a person object directly ...
p1 <- person("Karl", "Pearson", email = "pearson@stats.heaven")

## ... or convert a string.
p2 <- as.person("Ronald Aylmer Fisher")

## Combining and subsetting.
p <- c(p1, p2)
p[1]
p[-1]

## Extracting fields.
p$family
p$email
p[1]$email

## Specifying package authors, example from "boot":
## AC is the first author [aut] who wrote the S original.
## BR is the second author [aut], who translated the code to R [trl],
## and maintains the package [cre].
b <- c(person("Angelo", "Canty", role = "aut", comment =
  "S original, <http://statwww.epfl.ch/davison/BMA/library.html>"),
  person(c("Brian", "D."), "Ripley", role = c("aut", "trl", "cre"),
    comment = "R port", email = "ripley@stats.ox.ac.uk")
  )
b

## Formatting.
format(b)
format(b, include = c("family", "given", "role"),
```

```
braces = list(family = c("", ", "), role = c("(Role(s): ", ")))

## Conversion to BibTeX author field.
paste(format(b, include = c("given", "family")), collapse = " and ")
toBibtex(b)

## ORCID identifiers.
(p3 <- person("Achim", "Zeileis",
              comment = c(ORCID = "0000-0003-0918-3766")))
```

---

personList

*Collections of Persons (Older Interface)*

---

### Description

Old interface providing functionality for information about collections of persons. Since R 2.14.0 [person](#) objects can be combined with the corresponding `c` method which supersedes the `personList` function.

### Usage

```
personList(...)
as.personList(x)
```

### Arguments

|                  |   |
|------------------|---|
| <code>...</code> | person objects (inheriting from class " <a href="#">person</a> ")           |
| <code>x</code>   | an object the elements of which are coercible via <a href="#">as.person</a> |

### Value

a person object (inheriting from class "[person](#)")

### See Also

[person](#) for the new functionality for representing and manipulating information about persons.

---

PkgUtils

*Utilities for Building and Checking Add-on Packages*

---

### Description

Utilities for checking whether the sources of an R add-on package work correctly, and for building a source package from them.

### Usage

```
R CMD check [options] pkgdirs
R CMD build [options] pkgdirs
```

## Arguments

|                      |  |
|----------------------|--|
| <code>pkgdirs</code> | a list of names of directories with sources of R add-on packages. For check these can also be the filenames of compressed tar archives with extension <code>‘.tar.gz’</code> , <code>‘.tgz’</code> , <code>‘.tar.bz2’</code> or <code>‘.tar.xz’</code> . |
| <code>options</code> | further options to control the processing, or for obtaining information about usage and version of the utility.  |

## Details

R CMD `check` checks R add-on packages from their sources, performing a wide variety of diagnostic checks.

R CMD `build` builds R source tarballs. The name(s) of the packages are taken from the `‘DESCRIPTION’` files and not from the directory names. This works entirely on a copy of the supplied source directories.

Use R CMD `foo --help` to obtain usage information on utility `foo`, notably the possible options.

The defaults for some of the options to R CMD `build` can be set by environment variables `_R_BUILD_RESAVE_DATA_` and `_R_BUILD_COMPACT_VIGNETTES_`: see `‘Writing R Extensions’`. Many of the checks in R CMD `check` can be turned off or on by environment variables: see Chapter `‘Tools’` of the `‘R Internals’` manual.

By default R CMD `build` uses the `"internal"` option to `tar` to prepare the tarball. An external `tar` program can be specified by the `R_BUILD_TAR` environment variable. This may be substantially faster for very large packages, and can be needed for packages with long path names (over 100 bytes) or very large files (over 8GB): however, the resulting tarball may not be portable.

R CMD `check` by default unpacks tarballs by the internal `untar` function: if needed an external `tar` command can be specified by the environment variable `R_INSTALL_TAR`: please ensure that it can handle the type of compression used on the tarball. (This is sometimes needed for tarballs containing invalid or unsupported sections, and can be faster on very large tarballs. Setting `R_INSTALL_TAR` to `‘tar.exe’` has been needed to overcome permissions issues on some Windows systems.)

## Note

Only on Windows: They make use of a temporary directory specified by the environment variable `TMPDIR` and defaulting to `‘c:/TEMP’`. Do ensure that if set forward slashes are used.

## See Also

The sections on `‘Checking and building packages’` and `‘Processing documentation files’` in `‘Writing R Extensions’`: `RShowDoc("R-exts")`.

## Description

R front ends like the Windows GUI handle key presses and mouse clicks through “events” generated by the OS. These are processed automatically by R at intervals during computations, but in some cases it may be desirable to trigger immediate event handling. The `process.events` function does that.

**Usage**

```
process.events()
```

**Details**

This is a simple wrapper for the C API function `R_ProcessEvents`. As such, it is possible that it will not return if the user has signalled to interrupt the calculation.

**Value**

NULL is returned invisibly.

**Author(s)**

Duncan Murdoch

**See Also**

See ‘Writing R Extensions’ and the ‘R for Windows FAQ’ for more discussion of the `R_ProcessEvents` function.

---

prompt

*Produce Prototype of an R Documentation File*

---

**Description**

Facilitate the constructing of files documenting R objects.

**Usage**

```
prompt(object, filename = NULL, name = NULL, ...)

## Default S3 method:
prompt(object, filename = NULL, name = NULL,
       force.function = FALSE, ...)

## S3 method for class 'data.frame'
prompt(object, filename = NULL, name = NULL, ...)

promptImport(object, filename = NULL, name = NULL,
             importedFrom = NULL, importPage = name, ...)
```

**Arguments**

|                       |  |
|-----------------------|--|
| <code>object</code>   | an R object, typically a function for the default method. Can be <a href="#">missing</a> when name is specified.   |
| <code>filename</code> | usually, a <a href="#">connection</a> or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is <code>name</code> followed by <code>".Rd"</code> . Can also be NA (see below). |
| <code>name</code>     | a character string specifying the name of the object.  |

|                             |   |
|-----------------------------|---|
| <code>force.function</code> | a logical. If TRUE, treat <code>object</code> as function in any case.  |
| <code>...</code>            | further arguments passed to or from other methods.  |
| <code>importedFrom</code>   | a character string naming the package from which <code>object</code> was imported. Defaults to the environment of <code>object</code> if <code>object</code> is a function. |
| <code>importPage</code>     | a character string naming the help page in the package from which <code>object</code> was imported.   |

## Details

Unless `filename` is NA, a documentation shell for `object` is written to the file specified by `filename`, and a message about this is given. For function objects, this shell contains the proper function and argument names. R documentation files thus created still need to be edited and moved into the ‘man’ subdirectory of the package containing the object to be documented.

If `filename` is NA, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n")`, where `x` is the list-style representation.

When `prompt` is used in `for` loops or scripts, the explicit name specification will be useful.

The `importPage` argument for `promptImport` needs to give the base of the name of the help file of the original help page. For example, the `approx` function is documented in ‘`approxfun.Rd`’ in the **stats** package, so if it were imported and re-exported it should have `importPage = "approxfun"`. Objects that are imported from other packages are not normally documented unless re-exported.

## Value

If `filename` is NA, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

## Warning

The default `filename` may not be a valid filename under limited file systems (e.g., those on Windows).

Currently, calling `prompt` on a non-function object assumes that the object is in fact a data set and hence documents it as such. This may change in future versions of R. Use `promptData` to create documentation skeletons for data sets.

## Note

The documentation file produced by `prompt.data.frame` does not have the same format as many of the data frame documentation files in the **base** package. We are trying to settle on a preferred format for the documentation.

## Author(s)

Douglas Bates for `prompt.data.frame`

To prompt the user for input, see [readline](#).

**Examples**

```
require(graphics)

prompt(plot.default)
prompt(interactive, force.function = TRUE)
unlink("plot.default.Rd")
unlink("interactive.Rd")

prompt(women) # data.frame
unlink("women.Rd")

prompt(sunspots) # non-data.frame data
unlink("sunspots.Rd")

## Not run:
## Create a help file for each function in the .GlobalEnv:
for(f in ls()) if(is.function(get(f))) prompt(name = f)

## End(Not run)
```

---

promptData

*Generate Outline Documentation for a Data Set*

---

**Description**

Generates a shell of documentation for a data set.

**Usage**

```
promptData(object, filename = NULL, name = NULL)
```

**Arguments**

|          |   |
|----------|---|
| object   | an R object to be documented as a data set.   |
| filename | usually, a <a href="#">connection</a> or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is name followed by ".Rd". Can also be NA (see below). |
| name     | a character string specifying the name of the object.   |

## Details

Unless `filename` is `NA`, a documentation shell for `object` is written to the file specified by `filename`, and a message about this is given.

If `filename` is `NA`, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n")`, where `x` is the list-style representation.

Currently, only data frames are handled explicitly by the code.

## Value

If `filename` is `NA`, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

## See Also

[prompt](#)

## Examples

```
promptData(sunspots)
unlink("sunspots.Rd")
```

---

promptPackage

*Generate a Shell for Documentation of a Package*

---

## Description

Generates a prototype of a package overview help page using Rd macros that dynamically extract information from package metadata when building the package.

## Usage

```
promptPackage(package, lib.loc = NULL, filename = NULL,
              name = NULL, final = FALSE)
```

## Arguments

|                       |   |
|-----------------------|---|
| <code>package</code>  | a <a href="#">character</a> string with the name of the package to be documented.   |
| <code>lib.loc</code>  | ignored.  |
| <code>filename</code> | usually, a <a href="#">connection</a> or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is <code>name</code> followed by <code>".Rd"</code> . Can also be <code>NA</code> (see below). |
| <code>name</code>     | a character string specifying the name of the help topic; defaults to <code>"pkgname-package"</code> , which is the required <code>\alias</code> for the overview help page.  |
| <code>final</code>    | a logical value indicating whether to attempt to create a usable version of the help topic, rather than just a shell.   |

**Details**

Unless `filename` is `NA`, a documentation shell for `package` is written to the file specified by `filename`, and a message about this is given.

If `filename` is `NA`, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n")`, where `x` is the list-style representation.

If `final` is `TRUE`, the generated documentation will not include the place-holder slots for manual editing, it will be usable as-is. In most cases a manually edited file is preferable (but `final = TRUE` is certainly less work).

**Value**

If `filename` is `NA`, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

**See Also**

[prompt](#), [package.skeleton](#)

**Examples**

```
filename <- tempfile()
promptPackage("utils", filename = filename)
file.show(filename)
unlink(filename)
```

---

Question

*Documentation Shortcuts*

---

**Description**

These functions provide access to documentation. Documentation on a topic with name `name` (typically, an R object or a data set) can be displayed by either `help("name")` or `?name`.

**Usage**

```
?topic
```

```
type?topic
```

**Arguments**

|                    |  |
|--------------------|--|
| <code>topic</code> | Usually, a <a href="#">name</a> or character string specifying the topic for which help is sought. Alternatively, a function call to ask for documentation on a corresponding S4 method: see the section on S4 method documentation. The calls <code>pkg : : topic</code> and <code>pkg : : : topic</code> are treated specially, and look for help on <code>topic</code> in package <code>pkg</code> .  |
| <code>type</code>  | the special type of documentation to use for this topic; for example, type <code>package</code> will look for the overview help page of a package named <code>topic</code> , and if the type is <code>class</code> , documentation is provided for the S4 class with name <code>topic</code> . See the Section ‘S4 Method Documentation’ for the uses of <code>type</code> to get help on formal methods, including <code>methods?function</code> and <code>method?call</code> . |

## Details

This is a shortcut to [help](#) and uses its default type of help.

Some topics need to be quoted (by [backticks](#)) or given as a character string. There include those which cannot syntactically appear on their own such as unary and binary operators, `function` and control-flow [reserved](#) words (including `if`, `else` `for`, `in`, `repeat`, `while`, `break` and `next`). The other reserved words can be used as if they were names, for example `TRUE`, `NA` and `Inf`.

## S4 Method Documentation

Authors of formal ('S4') methods can provide documentation on specific methods, as well as overall documentation on the methods of a particular function. The `"?"` operator allows access to this documentation in three ways.

The expression `methods?f` will look for the overall documentation methods for the function `f`. Currently, this means the documentation file containing the alias `f-methods`.

There are two different ways to look for documentation on a particular method. The first is to supply the `topic` argument in the form of a function call, omitting the `type` argument. The effect is to look for documentation on the method that would be used if this function call were actually evaluated. See the examples below. If the function is not a generic (no S4 methods are defined for it), the help reverts to documentation on the function name.

The `"?"` operator can also be called with `type` supplied as `method`; in this case also, the `topic` argument is a function call, but the arguments are now interpreted as specifying the class of the argument, not the actual expression that will appear in a real call to the function. See the examples below.

The first approach will be tedious if the actual call involves complicated expressions, and may be slow if the arguments take a long time to evaluate. The second approach avoids these issues, but you do have to know what the classes of the actual arguments will be when they are evaluated.

Both approaches make use of any inherited methods; the signature of the method to be looked up is found by using `selectMethod` (see the documentation for [getMethod](#)). A limitation is that methods in packages (as opposed to regular functions) will only be found if the package exporting them is on the search list, even if it is specified explicitly using the `?package::generic()` notation.

*A Completion Generator for R*

---

## Description

This page documents a mechanism to generate relevant completions from a partially completed command line. It is not intended to be useful by itself, but rather in conjunction with other mechanisms that use it as a backend. The functions listed in the usage section provide a simple control and query mechanism. The actual interface consists of a few unexported functions described further down.

## Usage

```

rc.settings(ops, ns, args, dots, func, ipck, S3, data, help,
            argdb, fuzzy, quotes, files, backtick)

rc.status()
rc.getOption(name)
rc.options(...)

.DollarNames(x, pattern)
.AtNames(x, pattern)

## Default S3 method:
.DollarNames(x, pattern = "")
## S3 method for class 'list'
.DollarNames(x, pattern = "")
## S3 method for class 'environment'

```

```
.DollarNames(x, pattern = "")
## Default S3 method:
.AtNames(x, pattern = "")

findMatches(pattern, values, fuzzy, backtick)
```

## Arguments

|          |   |
|----------|---|
| ops      | Logical flag. Activates completion after the \$ and @ operators.  |
| ns       | Logical flag. Controls namespace related completions.   |
| args     | Logical flag. Enables completion of function arguments.   |
| dots     | Logical flag. If disabled, drops . . . from list of function arguments. Relevant only if args is enabled.   |
| func     | Logical flag. Enables detection of functions. If enabled, a customizable extension ( " ( " by default) is appended to function names. The process of determining whether a potential completion is a function requires evaluation, including for lazy loaded symbols. This is undesirable for large objects, because of potentially wasteful use of memory in addition to the time overhead associated with loading. For this reason, this feature is disabled by default.  |
| S3       | Logical flag. When args = TRUE, activates completion on arguments of all S3 methods (otherwise just the generic, which usually has very few arguments).   |
| ipck     | Logical flag. Enables completion of installed package names inside <a href="#">library</a> and <a href="#">require</a> .  |
| data     | Logical flag. Enables completion of data sets (including those already visible) inside <a href="#">data</a> .   |
| help     | Logical flag. Enables completion of help requests starting with a question mark, by looking inside help index files.  |
| argdb    | Logical flag. When args = TRUE, completion is attempted on function arguments. Generally, the list of valid arguments is determined by dynamic calls to <a href="#">args</a> . While this gives results that are technically correct, the use of the . . . argument often hides some useful arguments. To give more flexibility in this regard, an optional table of valid arguments names for specific functions is retained internally. Setting argdb = TRUE enables preferential lookup in this internal data base for functions with an entry in it. Of course, this is useful only when the data base contains information about the function of interest. Some functions are already included, and more can be added by the user through the unexported function <code>.addFunctionInfo</code> (see below). |
| fuzzy    | Logical flag. Enables fuzzy matching, where close but non-exact matches (e.g., with different case) are considered if no exact matches are found. This feature is experimental and the details can change. In <code>findMatches</code> , this argument defaults to the current setting.   |
| backtick | Logical flag. If enabled, non-syntactic completions are wrapped in backticks to make them syntactically valid. This is useful only if the backend can handle such completions. In <code>findMatches</code> , this argument defaults to the current setting.   |
| quotes   | Logical flag. Enables completion in R code when inside quotes. This normally leads to filename completion, but can be otherwise depending on context (for example, when the open quote is preceded by ?), help completion is invoked.   |

|                        |   |
|------------------------|---|
|                        | Setting this to <code>FALSE</code> relegates completion to the underlying completion front-end, which may do its own processing (for example, <code>readline</code> on Unix-alikes will do filename completion).  |
| <code>files</code>     | Logical flag. Deprecated. Use <code>quotes</code> instead.  |
| <code>name, ...</code> | user-settable options. Currently valid names are<br><code>function.suffix</code> : default <code>" ("</code><br><code>funarg.suffix</code> : default <code>"="</code><br><code>package.suffix</code> default <code>" : "</code><br>Usage is similar to that of <code>options</code> . |
| <code>x</code>         | An R object for which valid names after <code>"\$"</code> are computed and returned.  |
| <code>pattern</code>   | A regular expression. Only matching names are returned.   |
| <code>values</code>    | character string giving set of candidate values in which matches are to be found.   |

## Details

There are several types of completion, some of which can be disabled using `rc.settings`. The arguments of `rc.settings` are all logical flags, turning specific optional completion features on and off. All settings are on by default except `ipck`, `func`, and `fuzzy`. Turn more off if your CPU cycles are valuable; you will still retain basic completion.

The most basic level, which can not be turned off once the completion functionality is activated, provides completion on names visible on the search path, along with a few special keywords (e.g., `TRUE`). This type of completion is not attempted if the partial ‘word’ (a.k.a. token) being completed is empty (since there would be too many completions). The more advanced types of completion are described below.

**Completion after extractors `$` and `@`:** When the `ops` setting is turned on, completion after `$` and `@` is attempted. This requires the prefix to be evaluated, which is attempted unless it involves an explicit function call (implicit function calls involving the use of `[`, `$`, etc *do not* inhibit evaluation).

Valid completions after the `$` and `@` extractors are determined by the generic functions `.DollarNames` and `.AtNames` respectively. A few basic methods are provided, and more can be written for custom classes. The `findMatches` function can be useful for this purpose.

**Completion inside namespaces:** When the `ns` setting is turned on, completion inside namespaces is attempted when a token is preceded by the `::` or `:::` operators. Additionally, the basic completion mechanism is extended to include all loaded namespaces, i.e., `foopkg::` becomes a valid completion of `foo` if `"foopkg"` is a loaded namespace.

The completion of package namespaces applies only to already loaded namespaces, i.e. if `MASS` is not loaded, `MAS` will not complete to `MASS::`. However, attempted completion *inside* an apparent namespace will attempt to load the namespace if it is not already loaded, e.g. trying to complete on `MASS::fr` will load `MASS` if it is not already loaded.

**Completion for help items:** When the `help` setting is turned on, completion on help topics is attempted when a token is preceded by `?`. Prefixes (such as `class`, `method`) are supported, as well as quoted help topics containing special characters.

**Completion of function arguments:** When the `args` setting is turned on, completion on function arguments is attempted whenever deemed appropriate. The mechanism used will currently fail if the relevant function (at the point where completion is requested) was entered on a previous prompt (which implies in particular that the current line is being typed in response to a continuation prompt, usually `+`). Note that separation by newlines is fine.

The list of possible argument completions that is generated can be misleading. There is no problem for non-generic functions (except that `...` is listed as a completion; this is intentional as it signals the fact that the function can accept further arguments). However, for generic functions, it is practically impossible to give a reliable argument list without evaluating arguments (and not even then, in some cases), which is risky (in addition to being difficult to code, which is the real reason it hasn't even been tried), especially when that argument is itself an inline function call. Our compromise is to consider arguments of *all* currently available methods of that generic. This has two drawbacks. First, not all listed completions may be appropriate in the call currently being constructed. Second, for generics with many methods (like `print` and `plot`), many matches will need to be considered, which may take a noticeable amount of time. Despite these drawbacks, we believe this behaviour to be more useful than the only other practical alternative, which is to list arguments of the generic only.

Only S3 methods are currently supported in this fashion, and that can be turned off using the `S3` setting.

Since arguments can be unnamed in R function calls, other types of completion are also appropriate whenever argument completion is. Since there are usually many more visible objects than formal arguments of any particular function, possible argument completions are often buried in a bunch of other possibilities. However, recall that basic completion is suppressed for blank tokens. This can be useful to list possible arguments of a function. For example, trying to complete `seq([TAB]` and `seq(from = 1, [TAB])` will both list only the arguments of `seq` (or any of its methods), whereas trying to complete `seq(length[TAB]` will list both the `length.out` argument and the `length()` function as possible completions. Note that no attempt is made to remove arguments already supplied, as that would incur a further speed penalty.

**Special functions:** For a few special functions (`library`, `data`, etc), the first argument is treated specially, in the sense that normal completion is suppressed, and some function specific completions are enabled if so requested by the settings. The `ipck` setting, which controls whether `library` and `require` will complete on *installed packages*, is disabled by default because the first call to `installed.packages` is potentially time consuming (e.g., when packages are installed on a remote network file server). Note, however, that the results of a call to `installed.packages` is cached, so subsequent calls are usually fast, so turning this option on is not particularly onerous even in such situations.

`findMatches` is an utility function that is used internally to determine matches. It can be used for writing methods for `.DollarNames` or `.AtNames`, the main benefit being that it will take the current `fuzzy` setting into account.

## Value

If `rc.settings` is called without any arguments, it returns the current settings as a named logical vector. Otherwise, it returns `NULL` invisibly.

`rc.status` returns, as a list, the contents of an internal (unexported) environment that is used to record the results of the last completion attempt. This can be useful for debugging. For such use, one must resist the temptation to use completion when typing the call to `rc.status` itself, as that then becomes the last attempt by the time the call is executed.

The items of primary interest in the returned list are:

|                    |  |
|--------------------|--|
| <code>comps</code> | The possible completions generated by the last call to <code>.completeToken</code> , as a character vector.  |
| <code>token</code> | The token that was (or, is to be) completed, as set by the last call to <code>.assignToken</code> (possibly inside a call to <code>.guessTokenFromLine</code> ). |

|                         |  |
|-------------------------|--|
| <code>linebuffer</code> | The full line, as set by the last call to <code>.assignLinebuffer</code> .                                 |
| <code>start</code>      | The start position of the token in the line buffer, as set by the last call to <code>.assignStart</code> . |
| <code>end</code>        | The end position of the token in the line buffer, as set by the last call to <code>.assignEnd</code> .     |
| <code>fileName</code>   | Logical, indicating whether the cursor is currently inside quotes.   |
| <code>fguess</code>     | The name of the function the cursor is currently inside.   |
| <code>isFirstArg</code> | Logical. If cursor is inside a function, is it the first argument?   |

In addition, the components `settings` and `options` give the current values of settings and options respectively.

`rc.getOption` and `rc.options` behave much like `getOption` and `options` respectively.

`findMatches` returns values that match the input pattern, taking the `fuzzy` flag into account.

## Unexported API

There are several unexported functions in the package. Of these, a few are special because they provide the API through which other mechanisms can make use of the facilities provided by this package (they are unexported because they are not meant to be called directly by users). The usage of these functions are:

```
.assignToken(text)
.assignLinebuffer(line)
.assignStart(start)
.assignEnd(end)

.completeToken(custom = TRUE)
.retrieveCompletions()
.getFileComp()

.guessTokenFromLine()
.win32consoleCompletion(linebuffer, cursorPosition,
                        check.repeat = TRUE,
                        minlength = -1)

.addFunctionInfo(...)
```

The first four functions set up a completion attempt by specifying the token to be completed (`text`), and indicating where (`start` and `end`, which should be integers) the token is placed within the complete line typed so far (`line`).

Potential completions of the token are generated by `.completeToken`, and the completions can be retrieved as an R character vector using `.retrieveCompletions`. It is possible for the user to specify a replacement for this function by setting `rc.options("custom.completer")`; if not `NULL`, this function is called to compute potential completions. This facility is meant to help in situations where completing as R code is not appropriate. See source code for more details. Custom completion can be disabled by setting `custom = FALSE` when calling `.completeToken`.

If the cursor is inside quotes, completion may be suppressed. The function `.getFileComp` can be used after a call to `.completeToken` to determine if this is the case (returns `TRUE`), and alternative completions generated as deemed useful. In most cases, filename completion is a reasonable fallback.

The `.guessTokenFromLine` function is provided for use with backends that do not already break a line into tokens. It requires the `linebuffer` and `endpoint` (cursor position) to be already set, and itself sets the token and the start position. It returns the token as a character string.

The `.win32consoleCompletion` is similar in spirit, but is more geared towards the Windows GUI (or rather, any front-end that has no completion facilities of its own). It requires the `linebuffer` and cursor position as arguments, and returns a list with three components, `addition`, `possible` and `comps`. If there is an unambiguous extension at the current position, `addition` contains the additional text that should be inserted at the cursor. If there is more than one possibility, these are available either as a character vector of preformatted strings in `possible`, or as a single string in `comps`. `possible` consists of lines formatted using the current `width` option, so that printing them on the console one line at a time will be a reasonable way to list them. `comps` is a space separated (collapsed) list of the same completions, in case the front-end wishes to display it in some other fashion.

The `minlength` argument can be used to suppress completion when the token is too short (which can be useful if the front-end is set up to try completion on every keypress). If `check.repeat` is `TRUE`, it is detected if the same completion is being requested more than once in a row, and ambiguous completions are returned only in that case. This is an attempt to emulate GNU Readline behaviour, where a single TAB completes up to any unambiguous part, and multiple possibilities are reported only on two consecutive TABs.

As the various front-end interfaces evolve, the details of these functions are likely to change as well.

The function `.addFunctionInfo` can be used to add information about the permitted argument names for specific functions. Multiple named arguments are allowed in calls to it, where the tags are names of functions and values are character vectors representing valid arguments. When the `argdb` setting is `TRUE`, these are used as a source of valid argument names for the relevant functions.

## Note

If you are uncomfortable with unsolicited evaluation of pieces of code, you should set `ops = FALSE`. Otherwise, trying to complete `foo@ba` will evaluate `foo`, trying to complete `foo[i, 1:10]$ba` will evaluate `foo[i, 1:10]`, etc. This should not be too bad, as explicit function calls (involving parentheses) are not evaluated in this manner. However, this *will* affect promises and lazy loaded symbols.

## Author(s)

Deepayan Sarkar, <deepayan.sarkar@r-project.org>

## Description

Reads a file in Data Interchange Format (DIF) and creates a data frame from it. DIF is a format for data matrices such as single spreadsheets.

**Usage**

```
read.DIF(file, header = FALSE,
         dec = ".", numerals = c("allow.loss", "warn.loss", "no.loss"),
         row.names, col.names, as.is = !stringsAsFactors,
         na.strings = "NA", colClasses = NA, nrow = -1,
         skip = 0, check.names = TRUE, blank.lines.skip = TRUE,
         stringsAsFactors = FALSE,
         transpose = FALSE, fileEncoding = "")
```

**Arguments**

- |            |  |
|------------|--|
| file       | <p>the name of the file which the data are to be read from, or a <a href="#">connection</a>, or a complete URL.</p> <p>The name "clipboard" may also be used on Windows, in which case <code>read.DIF("clipboard")</code> will look for a DIF format entry in the Windows clipboard.</p>   |
| header     | <p>a logical value indicating whether the spreadsheet contains the names of the variables as its first line. If missing, the value is determined from the file format: <code>header</code> is set to <code>TRUE</code> if and only if the first row contains only character values and the top left cell is empty.</p>   |
| dec        | <p>the character used in the file for decimal points.</p>  |
| numerals   | <p>string indicating how to convert numbers whose conversion to double precision would lose accuracy, see <a href="#">type.convert</a>.</p>  |
| row.names  | <p>a vector of row names. This can be a vector giving the actual row names, or a single number giving the column of the table which contains the row names, or character string giving the name of the table column containing the row names.</p> <p>If there is a header and the first row contains one fewer field than the number of columns, the first column in the input is used for the row names. Otherwise if <code>row.names</code> is missing, the rows are numbered.</p> <p>Using <code>row.names = NULL</code> forces row numbering.</p>  |
| col.names  | <p>a vector of optional names for the variables. The default is to use "V" followed by the column number.</p>  |
| as.is      | <p>controls conversion of character variables (insofar as they are not converted to logical, numeric or complex) to factors, if not otherwise specified by <code>colClasses</code>. Its value is either a vector of logicals (values are recycled if necessary), or a vector of numeric or character indices which specify which columns should not be converted to factors.</p> <p>Note: In releases prior to R 2.12.1, cells marked as being of character type were converted to logical, numeric or complex using <a href="#">type.convert</a> as in <a href="#">read.table</a>.</p> <p>Note: to suppress all conversions including those of numeric columns, set <code>colClasses = "character"</code>.</p> <p>Note that <code>as.is</code> is specified per column (not per variable) and so includes the column of row names (if any) and any columns to be skipped.</p> |
| na.strings | <p>a character vector of strings which are to be interpreted as <a href="#">NA</a> values. Blank fields are also considered to be missing values in logical, integer, numeric and complex fields.</p>  |

|                               |  |
|-------------------------------|--|
| <code>colClasses</code>       | <p>character. A vector of classes to be assumed for the columns. Recycled as necessary, or if the character vector is named, unspecified values are taken to be NA.</p> <p>Possible values are NA (when <code>type.convert</code> is used), "NULL" (when the column is skipped), one of the atomic vector classes (logical, integer, numeric, complex, character, raw), or "factor", "Date" or "POSIXct". Otherwise there needs to be an <code>as</code> method (from package <b>methods</b>) for conversion from "character" to the specified formal class.</p> <p>Note that <code>colClasses</code> is specified per column (not per variable) and so includes the column of row names (if any).</p> |
| <code>nrows</code>            | the maximum number of rows to read in. Negative values are ignored.  |
| <code>skip</code>             | the number of lines of the data file to skip before beginning to read data.  |
| <code>check.names</code>      | logical. If TRUE then the names of the variables in the data frame are checked to ensure that they are syntactically valid variable names. If necessary they are adjusted (by <code>make.names</code> ) so that they are, and also to ensure that there are no duplicates.   |
| <code>blank.lines.skip</code> | logical: if TRUE blank lines in the input are ignored.   |
| <code>stringsAsFactors</code> | logical: should character vectors be converted to factors?   |
| <code>transpose</code>        | logical, indicating if the row and column interpretation should be transposed. Microsoft's Excel has been known to produce (non-standard conforming) DIF files which would need <code>transpose = TRUE</code> to be read correctly.  |
| <code>fileEncoding</code>     | character string: if non-empty declares the encoding used on a file (not a connection or clipboard) so the character data can be re-encoded. See the 'Encoding' section of the help for <code>file</code> , the 'R Data Import/Export' manual and 'Note'.  |

### Value

A data frame (`data.frame`) containing a representation of the data in the file. Empty input is an error unless `col.names` is specified, when a 0-row data frame is returned: similarly giving just a header line if `header = TRUE` results in a 0-row data frame.

### Note

The columns referred to in `as.is` and `colClasses` include the column of row names (if any).  
 Less memory will be used if `colClasses` is specified as one of the six atomic vector classes.

### Author(s)

R Core; `transpose` option by Christoph Buser, ETH Zurich

### References

The DIF format specification can be found by searching on <http://www.wotsit.org/>; the optional header fields are ignored. See also [https://en.wikipedia.org/wiki/Data\\_Interchange\\_Format](https://en.wikipedia.org/wiki/Data_Interchange_Format).

The term is likely to lead to confusion: Windows will have a 'Windows Data Interchange Format (DIF) data format' as part of its WinFX system, which may or may not be compatible.

The *R Data Import/Export* manual.

[scan](#), [type.convert](#), [read.fwf](#) for reading fixed width formatted input; [read.table](#); [data.frame](#).

**Examples**

```
## read.DIF() may need transpose = TRUE for a file exported from Excel
udir <- system.file("misc", package = "utils")
dd <- read.DIF(file.path(udir, "exDIF.dif"), header = TRUE, transpose = TRUE)
dc <- read.csv(file.path(udir, "exDIF.csv"), header = TRUE)
stopifnot(identical(dd, dc), dim(dd) == c(4,2))
```

---

read.fortran

*Read Fixed-Format Data in a Fortran-like Style*

---

**Description**

Read fixed-format data files using Fortran-style format specifications.

**Usage**

```
read.fortran(file, format, ..., as.is = TRUE, colClasses = NA)
```

**Arguments**

|            |  |
|------------|--|
| file       | File or <a href="#">connection</a> to read from.                                   |
| format     | Character vector or list of vectors. See ‘Details’ below.                          |
| ...        | Other arguments for <a href="#">read.fwf</a> .                                     |
| as.is      | Keep characters as characters?   |
| colClasses | Variable classes to override defaults. See <a href="#">read.table</a> for details. |

**Details**

The format for a field is of one of the following forms: `rFl.d`, `rDl.d`, `rXl`, `rAl`, `rIl`, where `l` is the number of columns, `d` is the number of decimal places, and `r` is the number of repeats. `F` and `D` are numeric formats, `A` is character, `I` is integer, and `X` indicates columns to be skipped. The repeat code `r` and decimal place code `d` are always optional. The length code `l` is required except for `X` formats when `r` is present.

For a single-line record, `format` should be a character vector. For a multiline record it should be a list with a character vector for each line.

Skipped (`X`) columns are not passed to `read.fwf`, so `colClasses`, `col.names`, and similar arguments passed to `read.fwf` should not reference these columns.

**Value**

A data frame

**Note**

`read.fortran` does not use actual Fortran input routines, so the formats are at best rough approximations to the Fortran ones. In particular, specifying `d > 0` in the `F` or `D` format will shift the decimal `d` places to the left, even if it is explicitly specified in the input file.

[read.fwf](#), [read.table](#), [read.csv](#)

**Examples**

```
ff <- tempfile()
cat(file = ff, "123456", "987654", sep = "\n")
read.fortran(ff, c("F2.1", "F2.0", "I2"))
read.fortran(ff, c("2F1.0", "2X", "2A1"))
unlink(ff)
cat(file = ff, "123456AB", "987654CD", sep = "\n")
read.fortran(ff, list(c("2F3.1", "A2"), c("3I2", "2X")))
unlink(ff)
# Note that the first number is read differently than Fortran would
# read it:
cat(file = ff, "12.3456", "1234567", sep = "\n")
read.fortran(ff, "F7.4")
unlink(ff)
```

---

read.fwf

*Read Fixed Width Format Files*

---

**Description**

Read a table of fixed width formatted data into a [data.frame](#).

**Usage**

```
read.fwf(file, widths, header = FALSE, sep = "\t",
         skip = 0, row.names, col.names, n = -1,
         buffersize = 2000, fileEncoding = "", ...)
```

**Arguments**

|                        |   |
|------------------------|---|
| <code>file</code>      | the name of the file which the data are to be read from.<br>Alternatively, <code>file</code> can be a <a href="#">connection</a> , which will be opened if necessary, and if so closed at the end of the function call. |
| <code>widths</code>    | integer vector, giving the widths of the fixed-width fields (of one line), or list of integer vectors giving widths for multiline records.  |
| <code>header</code>    | a logical value indicating whether the file contains the names of the variables as its first line. If present, the names must be delimited by <code>sep</code> .  |
| <code>sep</code>       | character; the separator used internally; should be a character that does not occur in the file (except in the header).   |
| <code>skip</code>      | number of initial lines to skip; see <a href="#">read.table</a> .   |
| <code>row.names</code> | see <a href="#">read.table</a> .  |

|                           |   |
|---------------------------|---|
| <code>col.names</code>    | see <a href="#">read.table</a> .  |
| <code>n</code>            | the maximum number of records (lines) to be read, defaulting to no limit.   |
| <code>buffer size</code>  | Maximum number of lines to read at one time   |
| <code>fileEncoding</code> | character string: if non-empty declares the encoding used on a file (not a connection) so the character data can be re-encoded. See the ‘Encoding’ section of the help for <a href="#">file</a> , the ‘R Data Import/Export’ manual and ‘Note’. |
| <code>...</code>          | further arguments to be passed to <a href="#">read.table</a> . Useful such arguments include <code>as.is</code> , <code>na.strings</code> , <code>colClasses</code> and <code>strip.white</code> .  |

## Details

Multiline records are concatenated to a single line before processing. Fields that are of zero-width or are wholly beyond the end of the line in `file` are replaced by NA.

Negative-width fields are used to indicate columns to be skipped, e.g., `-5` to skip 5 columns. These fields are not seen by `read.table` and so should not be included in a `col.names` or `colClasses` argument (nor in the header line, if present).

Reducing the `buffer size` argument may reduce memory use when reading large files with long lines. Increasing `buffer size` may result in faster processing when enough memory is available.

Note that `read.fwf` (not `read.table`) reads the supplied file, so the latter’s argument `encoding` will not be useful.

## Value

A [data.frame](#) as produced by [read.table](#) which is called internally.

## Author(s)

Brian Ripley for R version: originally in Perl by Kurt Hornik.

## See Also

[scan](#) and [read.table](#).

[read.fortran](#) for another style of fixed-format files.

## Examples

```
ff <- tempfile()
cat(file = ff, "123456", "987654", sep = "\n")
read.fwf(ff, widths = c(1,2,3))      #> 1 23 456 \ 9 87 654
read.fwf(ff, widths = c(1,-2,3))     #> 1 456 \ 9 654
unlink(ff)
cat(file = ff, "123", "987654", sep = "\n")
read.fwf(ff, widths = c(1,0, 2,3))    #> 1 NA 23 NA \ 9 NA 87 654
unlink(ff)
cat(file = ff, "123456", "987654", sep = "\n")
read.fwf(ff, widths = list(c(1,0, 2,3), c(2,2,2))) #> 1 NA 23 456 98 76 54
unlink(ff)
```

|             |                                       |
|-------------|---------------------------------------|
| read.socket | <i>Read from or Write to a Socket</i> |
|-------------|---------------------------------------|

---

## Description

`read.socket` reads a string from the specified socket, `write.socket` writes to the specified socket. There is very little error checking done by either.

## Usage

```
read.socket(socket, maxlen = 256L, loop = FALSE)
write.socket(socket, string)
```

## Arguments

|                     |  |
|---------------------|--|
| <code>socket</code> | a socket object.                             |
| <code>maxlen</code> | maximum length (in bytes) of string to read. |
| <code>loop</code>   | wait for ever if there is nothing to read?   |
| <code>string</code> | string to write to socket.                   |

## Value

`read.socket` returns the string read as a length-one character vector.  
`write.socket` returns the number of bytes written.

## Author(s)

Thomas Lumley

## See Also

    stop("user name must be a string")
  user <- paste(user, "\r\n")
  socket <- make.socket(host, port)
  on.exit(close.socket(socket))
  write.socket(socket, user)
  output <- character(0)
  repeat{
    ss <- read.socket(socket)
    if (ss == "") break
    output <- paste(output, ss)
  }
  close.socket(socket)
  if (print) cat(output)
  invisible(output)
}
```

```

}
## Not run:
finger("root") ## only works if your site provides a finger daemon
## End(Not run)

```

read.table

*Data Input*

## Description

Reads a file in table format and creates a data frame from it, with cases corresponding to lines and variables to fields in the file.

## Usage

```

read.table(file, header = FALSE, sep = "", quote = "\"'",
  dec = ".", numerals = c("allow.loss", "warn.loss", "no.loss"),
  row.names, col.names, as.is = !stringsAsFactors, tryLogical = TRUE,
  na.strings = "NA", colClasses = NA, nrows = -1,
  skip = 0, check.names = TRUE, fill = !blank.lines.skip,
  strip.white = FALSE, blank.lines.skip = TRUE,
  comment.char = "#",
  allowEscapes = FALSE, flush = FALSE,
  stringsAsFactors = FALSE,
  fileEncoding = "", encoding = "unknown", text, skipNul = FALSE)

read.csv(file, header = TRUE, sep = ",", quote = "\"",
  dec = ".", fill = TRUE, comment.char = "", ...)

read.csv2(file, header = TRUE, sep = ";", quote = "\"",
  dec = ",", fill = TRUE, comment.char = "", ...)

read.delim(file, header = TRUE, sep = "\t", quote = "\"",
  dec = ".", fill = TRUE, comment.char = "", ...)

read.delim2(file, header = TRUE, sep = "\t", quote = "\"",
  dec = ",", fill = TRUE, comment.char = "", ...)

```

## Arguments

**file** the name of the file which the data are to be read from. Each row of the table appears as one line of the file. If it does not contain an *absolute* path, the file name is *relative* to the current working directory, `getwd()`. Tilde-expansion is performed where supported. This can be a compressed file (see [file](#)).

Alternatively, *file* can be a readable text-mode [connection](#) (which will be opened for reading if necessary, and if so `closed` (and hence destroyed) at the end of the function call). (If `stdin()` is used, the prompts for lines may be somewhat confusing. Terminate input with a blank line or an EOF signal, Ctrl-D on Unix and Ctrl-Z on Windows. Any pushback on `stdin()` will be cleared before return.)

*file* can also be a complete URL. (For the supported URL schemes, see the ‘URLs’ section of the help for [url](#).)

|            |   |
|------------|---|
| header     | a logical value indicating whether the file contains the names of the variables as its first line. If missing, the value is determined from the file format: <code>header</code> is set to <code>TRUE</code> if and only if the first row contains one fewer field than the number of columns.  |
| sep        | the field separator character. Values on each line of the file are separated by this character. If <code>sep = ""</code> (the default for <code>read.table</code> ) the separator is ‘white space’, that is one or more spaces, tabs, newlines or carriage returns.   |
| quote      | the set of quoting characters. To disable quoting altogether, use <code>quote = ""</code> . See <a href="#">scan</a> for the behaviour on quotes embedded in quotes. Quoting is only considered for columns read as character, which is all of them unless <code>colClasses</code> is specified.  |
| dec        | the character used in the file for decimal points.  |
| numerals   | string indicating how to convert numbers whose conversion to double precision would lose accuracy, see <a href="#">type.convert</a> . Can be abbreviated. (Applies also to complex-number inputs.)  |
| row.names  | <p>a vector of row names. This can be a vector giving the actual row names, or a single number giving the column of the table which contains the row names, or character string giving the name of the table column containing the row names. If there is a header and the first row contains one fewer field than the number of columns, the first column in the input is used for the row names. Otherwise if <code>row.names</code> is missing, the rows are numbered.</p> <p>Using <code>row.names = NULL</code> forces row numbering. Missing or <code>NULL</code> <code>row.names</code> generate row names that are considered to be ‘automatic’ (and not preserved by <a href="#">as.matrix</a>).</p> |
| col.names  | a vector of optional names for the variables. The default is to use "V" followed by the column number.  |
| as.is      | <p>controls conversion of character variables (insofar as they are not converted to logical, numeric or complex) to factors, if not otherwise specified by <code>colClasses</code>. Its value is either a vector of logicals (values are recycled if necessary), or a vector of numeric or character indices which specify which columns should not be converted to factors.</p> <p>Note: to suppress all conversions including those of numeric columns, set <code>colClasses = "character"</code>.</p> <p>Note that <code>as.is</code> is specified per column (not per variable) and so includes the column of row names (if any) and any columns to be skipped.</p>                                       |
| tryLogical | a <a href="#">logical</a> determining if columns consisting entirely of "F", "T", "FALSE", and "TRUE" should be converted to <a href="#">logical</a> ; passed to <a href="#">type.convert</a> , true by default.  |
| na.strings | a character vector of strings which are to be interpreted as <a href="#">NA</a> values. Blank fields are also considered to be missing values in logical, integer, numeric and complex fields. Note that the test happens <i>after</i> white space is stripped from the input (if enabled), so <code>na.strings</code> values may need their own white space stripped in advance.   |
| colClasses | <p>character. A vector of classes to be assumed for the columns. If unnamed, recycled as necessary. If named, names are matched with unspecified values being taken to be <code>NA</code>.</p> <p>Possible values are <code>NA</code> (the default, when <a href="#">type.convert</a> is used), <code>"NULL"</code> (when the column is skipped), one of the atomic vector classes (logical, integer, numeric, complex, character, raw), or <code>"factor"</code>, <code>"Date"</code> or <code>"POSIXct"</code>.</p>   |

|                               |  |
|-------------------------------|--|
|                               | Otherwise there needs to be an <code>as</code> method (from package <b>methods</b> ) for conversion from "character" to the specified formal class.<br>Note that <code>colClasses</code> is specified per column (not per variable) and so includes the column of row names (if any).  |
| <code>nrows</code>            | integer: the maximum number of rows to read in. Negative and other invalid values are ignored.   |
| <code>skip</code>             | integer: the number of lines of the data file to skip before beginning to read data.   |
| <code>check.names</code>      | logical. If <code>TRUE</code> then the names of the variables in the data frame are checked to ensure that they are syntactically valid variable names. If necessary they are adjusted (by <code>make.names</code> ) so that they are, and also to ensure that there are no duplicates.  |
| <code>fill</code>             | logical. If <code>TRUE</code> then in case the rows have unequal length, blank fields are implicitly added. See 'Details'.   |
| <code>strip.white</code>      | logical. Used only when <code>sep</code> has been specified, and allows the stripping of leading and trailing white space from unquoted character fields (numeric fields are always stripped). See <code>scan</code> for further details (including the exact meaning of 'white space'), remembering that the columns may include the row names. |
| <code>blank.lines.skip</code> | logical: if <code>TRUE</code> blank lines in the input are ignored.  |
| <code>comment.char</code>     | character: a character vector of length one containing a single character or an empty string. Use "" to turn off the interpretation of comments altogether.  |
| <code>allowEscapes</code>     | logical. Should C-style escapes such as '\n' be processed or read verbatim (the default)? Note that if not within quotes these could be interpreted as a delimiter (but not as a comment character). For more details see <code>scan</code> .  |
| <code>flush</code>            | logical: if <code>TRUE</code> , <code>scan</code> will flush to the end of the line after reading the last of the fields requested. This allows putting comments after the last field.   |
| <code>stringsAsFactors</code> | logical: should character vectors be converted to factors? Note that this is overridden by <code>as.is</code> and <code>colClasses</code> , both of which allow finer control.   |
| <code>fileEncoding</code>     | character string: if non-empty declares the encoding used on a file when given as a character string (not on an existing connection) so the character data can be re-encoded. See the 'Encoding' section of the help for <code>file</code> , the 'R Data Import/Export' manual and 'Note'.   |
| <code>encoding</code>         | encoding to be assumed for input strings. It is used to mark character strings as known to be in Latin-1 or UTF-8 (see <code>Encoding</code> ): it is not used to re-encode the input, but allows R to handle encoded strings in their native encoding (if one of those two). See 'Value' and 'Note'.  |
| <code>text</code>             | character string: if <code>file</code> is not supplied and this is, then data are read from the value of <code>text</code> via a text connection. Notice that a literal string can be used to include (small) data sets within R code.   |
| <code>skipNul</code>          | logical: should NULs be skipped?   |
| <code>...</code>              | Further arguments to be passed to <code>read.table</code> .  |

### Details

This function is the principal means of reading tabular data into R.

Unless `colClasses` is specified, all columns are read as character columns and then converted using `type.convert` to logical, integer, numeric, complex or (depending on `as.is`) factor as

appropriate. Quotes are (by default) interpreted in all fields, so a column of values like "42" will result in an integer column.

A field or line is 'blank' if it contains nothing (except whitespace if no separator is specified) before a comment character or the end of the field or line.

If `row.names` is not specified and the header line has one less entry than the number of columns, the first column is taken to be the row names. This allows data frames to be read in from the format in which they are printed. If `row.names` is specified and does not refer to the first column, that column is discarded from such files.

The number of data columns is determined by looking at the first five lines of input (or the whole input if it has less than five lines), or from the length of `col.names` if it is specified and is longer. This could conceivably be wrong if `fill` or `blank.lines.skip` are true, so specify `col.names` if necessary (as in the 'Examples').

`read.csv` and `read.csv2` are identical to `read.table` except for the defaults. They are intended for reading 'comma separated value' files (`.csv`) or (`read.csv2`) the variant used in countries that use a comma as decimal point and a semicolon as field separator. Similarly, `read.delim` and `read.delim2` are for reading delimited files, defaulting to the TAB character for the delimiter. Notice that `header = TRUE` and `fill = TRUE` in these variants, and that the comment character is disabled.

The rest of the line after a comment character is skipped; quotes are not processed in comments. Complete comment lines are allowed provided `blank.lines.skip = TRUE`; however, comment lines prior to the header must have the comment character in the first non-blank column.

Quoted fields with embedded newlines are supported except after a comment character. Embedded NULs are unsupported: skipping them (with `skipNul = TRUE`) may work.

## Value

A data frame ([data.frame](#)) containing a representation of the data in the file.

Empty input is an error unless `col.names` is specified, when a 0-row data frame is returned: similarly giving just a header line if `header = TRUE` results in a 0-row data frame. Note that in either case the columns will be logical unless `colClasses` was supplied.

Character strings in the result (including factor levels) will have a declared encoding if `encoding` is "latin1" or "UTF-8".

## CSV files

See the help on [write.csv](#) for the various conventions for `.csv` files. The commonest form of CSV file with row names needs to be read with `read.csv(..., row.names = 1)` to use the names in the first column of the file as row names.

## Memory usage

These functions can use a surprising amount of memory when reading large files. There is extensive discussion in the 'R Data Import/Export' manual, supplementing the notes here.

Less memory will be used if `colClasses` is specified as one of the six [atomic](#) vector classes. This can be particularly so when reading a column that takes many distinct numeric values, as storing each distinct value as a character string can take up to 14 times as much memory as storing it as an integer.

Using `nrows`, even as a mild over-estimate, will help memory usage.

Using `comment.char = ""` will be appreciably faster than the `read.table` default.

`read.table` is not the right tool for reading large matrices, especially those with many columns: it is designed to read *data frames* which may have columns of very different classes. Use [scan](#) instead for matrices.

### Note

The columns referred to in `as.is` and `colClasses` include the column of row names (if any).

There are two approaches for reading input that is not in the local encoding. If the input is known to be UTF-8 or Latin1, use the `encoding` argument to declare that. If the input is in some other encoding, then it may be translated on input. The `fileEncoding` argument achieves this by setting up a connection to do the re-encoding into the current locale. Note that on Windows or other systems not running in a UTF-8 locale, this may not be possible.

[count.fields](#) can be useful to determine problems with reading files which result in reports of incorrect record lengths (see the ‘Examples’ below).

<https://www.rfc-editor.org/rfc/rfc4180> for the IANA definition of CSV files (which requires comma as separator and CRLF line endings).

### Examples

```
## using count.fields to handle unknown maximum number of fields
## when fill = TRUE
test1 <- c(1:5, "6,7", "8,9,10")
tf <- tempfile()
writeLines(test1, tf)

read.csv(tf, fill = TRUE) # 1 column
ncol <- max(count.fields(tf, sep = ","))
read.csv(tf, fill = TRUE, header = FALSE,
         col.names = paste0("V", seq_len(ncol)))
unlink(tf)

## "Inline" data set, using text=
## Notice that leading and trailing empty lines are auto-trimmed

read.table(header = TRUE, text = "
a b
1 2
3 4
")
```

```

    readRegistry(gmt, "HLM")
  })
## Not run: ## on a 64-bit R need this to find 32-bit JAGS
readRegistry("SOFTWARE\\JAGS", maxdepth = 3, view = "32")

## See if there is a 64-bit user install
readRegistry("SOFTWARE\\R-core\\R64", "HCU", maxdepth = 2)

## End(Not run)

```

---

 recover

*Browsing after an Error*

---

## Description

This function allows the user to browse directly on any of the currently active function calls, and is suitable as an error option. The expression `options(error = recover)` will make this the error option.

## Usage

```
recover()
```

## Details

When called, `recover` prints the list of current calls, and prompts the user to select one of them. The standard R [browser](#) is then invoked from the corresponding environment; the user can type ordinary R language expressions to be evaluated in that environment.

When finished browsing in this call, type `c` to return to `recover` from the browser. Type another frame number to browse some more, or type `0` to exit `recover`.

The use of `recover` largely supersedes `dump.frames` as an error option, unless you really want to wait to look at the error. If `recover` is called in non-interactive mode, it behaves like `dump.frames`. For computations involving large amounts of data, `recover` has the advantage that it does not need to copy out all the environments in order to browse in them. If you do decide to quit interactive debugging, call `dump.frames` directly while browsing in any frame (see the examples).

## Value

Nothing useful is returned. However, you *can* invoke `recover` directly from a function, rather than through the error option shown in the examples. In this case, execution continues after you type `0` to exit `recover`.

## Compatibility Note

The R `recover` function can be used in the same way as the S function of the same name; therefore, the error option shown is a compatible way to specify the error action. However, the actual functions are essentially unrelated and interact quite differently with the user. The navigating commands `up` and `down` do not exist in the R version; instead, exit the browser and select another frame.

## References

```

---

relist

---

*Allow Re-Listing an unlist()ed Object*

---

## Description

`relist()` is an S3 generic function with a few methods in order to allow easy inversion of `unlist(obj)` when that is used with an object `obj` of (S3) class `"relistable"`.

## Usage

```
relist(flesh, skeleton)
## Default S3 method:
relist(flesh, skeleton = attr(flesh, "skeleton"))
## S3 method for class 'factor'
relist(flesh, skeleton = attr(flesh, "skeleton"))
## S3 method for class 'list'
relist(flesh, skeleton = attr(flesh, "skeleton"))
## S3 method for class 'matrix'
relist(flesh, skeleton = attr(flesh, "skeleton"))

as.relistable(x)
is.relistable(x)

## S3 method for class 'relistable'
unlist(x, recursive = TRUE, use.names = TRUE)
```

## Arguments

|                        |   |
|------------------------|---|
| <code>flesh</code>     | a vector to be relisted   |
| <code>skeleton</code>  | a list, the structure of which determines the structure of the result       |
| <code>x</code>         | an R object, typically a list (or vector).                                  |
| <code>recursive</code> | logical. Should unlisting be applied to list components of <code>x</code> ? |
| <code>use.names</code> | logical. Should names be preserved?   |

## Details

Some functions need many parameters, which are most easily represented in complex structures, e.g., nested lists. Unfortunately, many mathematical functions in R, including `optim` and `nlm` can only operate on functions whose domain is a vector. R has `unlist()` to convert nested list objects into a vector representation. `relist()`, its methods and the functionality mentioned here provide the inverse operation to convert vectors back to the convenient structural representation. This allows structured functions (such as `optim()`) to have simple mathematical interfaces.

For example, a likelihood function for a multivariate normal model needs a variance-covariance matrix and a mean vector. It would be most convenient to represent it as a list containing a vector and a matrix. A typical parameter might look like

```
list(mean = c(0, 1), vcov = cbind(c(1, 1), c(1, 0))).
```

However, `optim` cannot operate on functions that take lists as input; it only likes numeric vectors. The solution is conversion. Given a function `mvdnorm(x, mean, vcov, log = FALSE)` which computes the required probability density, then

```
ipar <- list(mean = c(0, 1), vcov = cbind(c(1, 1), c(1, 0)))
initial.param <- as.relistable(ipar)

ll <- function(param.vector)
{
  param <- relist(param.vector, skeleton = ipar)
  -sum(mvdnorm(x, mean = param$mean, vcov = param$vcov,
              log = TRUE))
}
```

```

    }

    optim(unlist(initial.param), ll)

```

`relist` takes two parameters: `skeleton` and `flesh`. `Skeleton` is a sample object that has the right shape but the wrong content. `flesh` is a vector with the right content but the wrong shape. Invoking

```
relist(flesh, skeleton)
```

will put the content of `flesh` on the `skeleton`. You don't need to specify `skeleton` explicitly if the `skeleton` is stored as an attribute inside `flesh`. In particular, if `flesh` was created from some object `obj` with `unlist(as.relistable(obj))` then the `skeleton` attribute is automatically set. (Note that this does not apply to the example here, as `optim` is creating a new vector to pass to `ll` and not its `par` argument.)

As long as `skeleton` has the right shape, it should be an inverse of `unlist`. These equalities hold:

```

relist(unlist(x), x) == x
unlist(relist(y, skeleton)) == y

x <- as.relistable(x)
relist(unlist(x)) == x

```

Note however that the relisted object might not be *identical* to the `skeleton` because of implicit coercions performed during the unlisting step. All elements of the relisted objects have the same type as the unlisted object. `NULL` values are coerced to empty vectors of that type.

## Value

an object of (S3) class "relistable" (and "list").

## Author(s)

R Core, based on a code proposal by Andrew Clausen.

## See Also

`unlist`

## Examples

```

ipar <- list(mean = c(0, 1), vcov = cbind(c(1, 1), c(1, 0)))
initial.param <- as.relistable(ipar)
ul <- unlist(initial.param)
relist(ul)
stopifnot(identical(relist(ul), initial.param))

```

---

|        |                               |
|--------|-------------------------------|
| REMOVE | <i>Remove Add-on Packages</i> |
|--------|-------------------------------|

---

### Description

Utility for removing add-on packages.

### Usage

```
R CMD REMOVE [options] [-l lib] pkgs
```

### Arguments

|         |   |
|---------|---|
| pkgs    | a space-separated list with the names of the packages to be removed.  |
| lib     | the path name of the R library tree to remove from. May be absolute or relative. Also accepted in the form ‘--library=lib’. |
| options | further options for help or version.  |

### Details

If used as `R CMD REMOVE pkgs` without explicitly specifying `lib`, packages are removed from the library tree rooted at the first directory in the library path which would be used by R run in the current environment.

To remove from the library tree *lib* instead of the default one, use `R CMD REMOVE -l lib pkgs`.

Use `R CMD REMOVE --help` for more usage information.

### Note

Some binary distributions of R have REMOVE in a separate bundle, e.g. an R-devel RPM.

### See Also

---

|                 |                                  |
|-----------------|----------------------------------|
| remove.packages | <i>Remove Installed Packages</i> |
|-----------------|----------------------------------|

---

### Description

Removes installed packages/bundles and updates index information as necessary.

### Usage

```
remove.packages(pkgs, lib)
```

### Arguments

|      |  |
|------|--|
| pkgs | a character vector with the names of the packages to be removed.   |
| lib  | a character vector giving the library directories to remove the packages from. If missing, defaults to the first element in <code>.libPaths()</code> . |

**See Also**

On Unix-alikes, [REMOVE](#) for a command line version;  
[install.packages](#) for installing packages.

removeSource

*Remove Stored Source from a Function or Language Object***Description**

When `options("keep.source")` is `TRUE`, a copy of the original source code to a function is stored with it. Similarly, `parse()` may keep formatted source for an expression. Such source reference attributes are removed from the object by `removeSource()`.

**Usage**

```
removeSource(fn)
```

**Arguments**

`fn` a [function](#) or another language object (fulfilling [is.language](#)) from which to remove the source.

**Details**

This removes the `"srcref"` and related attributes, via *recursive* cleaning of `body(fn)` in the case of a function or the recursive language parts, otherwise.

**Value**

A copy of the `fn` object with the source removed.

**See Also**

[is.language](#) about language objects.

[srcref](#) for a description of source reference records, [deparse](#) for a description of how functions are deparsed.

**Examples**

```
## to make this act independently of the global 'options()' setting:
op <- options(keep.source = TRUE)
fn <- function(x) {
  x + 1 # A comment, kept as part of the source
}
fn
names(attributes(fn))          # "srcref" (only)
names(attributes(body(fn)))    # "srcref" "srcfile" "wholeSrcref"
f2 <- removeSource(fn)
f2
stopifnot(length(attributes(fn)) > 0,
           is.null(attributes(f2)),
           is.null(attributes(body(f2))))
```

```
## Source attribute of parse()d expressions,
##   have {"srcref", "srcfile", "wholeSrcref"} :
E  <- parse(text ="a <- x^y  # power")  ; names(attributes(E ))
E. <- removeSource(E)                  ; names(attributes(E.))
stopifnot(length(attributes(E )) > 0,
           is.null(attributes(E.)))
options(op) # reset to previous state
```

---

RHOME

*R Home Directory*

---

### Description

Returns the location of the R home directory, which is the root of the installed R tree.

### Usage

```
R RHOME
```

---

roman

*Roman Numerals*

---

### Description

Simple manipulation of (a small set of) integer numbers as roman numerals.

### Usage

```
as.roman(x)
.romans

r1 + r2
r1 <= r2
max(r1)
sum(r2)
```

### Arguments

|        |  |
|--------|--|
| x      | a numeric or character vector of arabic or roman numerals.   |
| r1, r2 | a roman number vector, i.e., of <code>class "roman"</code> . |

## Details

`as.roman` creates objects of class "roman" which are internally represented as integers, and have suitable methods for printing, formatting, subsetting, coercion, etc, see `methods(class = "roman")`.

Arithmetic ("[Arith](#)"), Comparison ("[Compare](#)") and ("[Logic](#)"), i.e., all "[Ops](#)" group operations work as for regular numbers via R's integer functionality.

Only numbers between 1 and 3999 have a unique representation as roman numbers, and hence others result in `as.roman(NA)`.

`.romans` is the basic dictionary, a named [character](#) vector.

## References

## Examples

```
## First five roman 'numbers'.
(y <- as.roman(1 : 5))
## Middle one.
y[3]
## Current year as a roman number.
(y <- as.roman(format(Sys.Date(), "%Y")))
## Today, and 10, 20, 30, and 100 years ago ...
y - 10*c(0:3,10)

## mixture of arabic and roman numbers :
as.roman(c(NA, 1:3, "", strrep("I", 1:6))) # + NA with a warning for "IIIIII"
cc <- c(NA, 1:3, strrep("I", 0:5))
(rc <- as.roman(cc)) # two NAs: 0 is not "roman"
(ic <- as.integer(rc)) # works automatically [without an explicit method]
rNA <- as.roman(NA)
## simple consistency checks -- arithmetic when result is in {1,2,...,3999} :
stopifnot(identical(rc, as.roman(rc)), # as.roman(.) is "idempotent"
  identical(rc + rc + (3*rc), rc*5),
  identical(ic, c(NA, 1:3, NA, 1:5)),
  identical(as.integer(5*rc), 5L*ic),
  identical(as.numeric(rc), as.numeric(ic)),
  identical(rc[1], rNA),
  identical(as.roman(0), rNA),
  identical(as.roman(NA_character_), rNA),
  identical(as.list(rc), as.list(ic)))
## Non-Arithmetic 'Ops' :
stopifnot(exprs = {
  # Comparisons :
  identical(ic < 1:5, rc < 1:5)
  identical(ic < 1:5, rc < as.roman(1:5))
  # Logic [integers |-> logical] :
  identical(rc & TRUE , ic & TRUE)
  identical(rc & FALSE, ic & FALSE)
  identical(rc | FALSE, ic | FALSE)
  identical(rc | NA , ic | NA)
})
```

```
## 'Summary' group functions (and comparison):
(rc. <- rc[!is.na(rc)])
stopifnot(exprs = {
  identical(min(rc), as.roman(NA))
  identical(min(rc, na.rm=TRUE),
    as.roman(min(ic, na.rm=TRUE)))
  identical(range(rc.),
    as.roman(range(as.integer(rc))))
  identical(sum(rc, na.rm=TRUE), as.roman("XXI"))
  identical(format(prod(rc, na.rm=TRUE)), "DCCXX")
  format(prod(rc.)) == "DCCXX"
})
```

Rprof

*Enable Profiling of R's Execution***Description**

Enable or disable profiling of the execution of R expressions.

**Usage**

```
Rprof(filename = "Rprof.out", append = FALSE, interval = 0.02,
  memory.profiling = FALSE, gc.profiling = FALSE,
  line.profiling = FALSE, filter.callframes = FALSE,
  numfiles = 100L, bufsize = 10000L,
  event = c("default", "cpu", "elapsed"))
```

**Arguments**

|                   |  |
|-------------------|--|
| filename          | The file to be used for recording the profiling results. Set to NULL or "" to disable profiling.   |
| append            | logical: should the file be over-written or appended to?   |
| interval          | real: distance (time interval) between samples in seconds.   |
| memory.profiling  | logical: write memory use information to the file?   |
| gc.profiling      | logical: record whether GC is running?   |
| line.profiling    | logical: write line locations to the file?   |
| filter.callframes | logical: filter out intervening call frames of the call tree. See the filtering out call frames section.   |
| numfiles, bufsize | integers: line profiling memory allocation   |
| event             | character: profiling event, character vector of length one, "elapsed" for elapsed (real, wall-clock) time and "cpu" for CPU time, both measured in seconds. "default" is the default event on the platform, one of the two. See the 'Details'. |

## Details

Enabling profiling automatically disables any existing profiling to another or the same file.

Profiling works by writing out the call stack every `interval` seconds (units of the profiling event), to the file specified. Either the `summaryRprof` function or the wrapper script `R CMD Rprof` can be used to process the output file to produce a summary of the usage; use `R CMD Rprof --help` for usage information.

Exactly what is measured is subtle and depends on the profiling event.

With `"elapsed"` (the default and only supported event on Windows): it is time that the R process is running and executing an R command. It is not however just CPU time, for if `readline()` is waiting for input, that counts as well. It is also known as ‘elapsed’ time.

With `"cpu"` (the default on Unix and typically the preferred event for identifying performance bottlenecks), it is CPU time of the R process, so for example excludes time when R is waiting for input or for processes run by `system` to return. It may go slower than `"elapsed"` when the process is often waiting for I/O to finish, but it may go faster with actively computing concurrent threads (say via OpenMP) on a multi-core system.

Note that the (timing) interval cannot be too small. With `"cpu"`, the time spent in each profiling step is currently added to the interval. With all profiling events, the computation in each profiling step causes perturbation to the observed system and biases the results. What is feasible is machine-dependent. On Linux, R requires the interval to be at least 10ms, on all other platforms at least 1ms. Shorter intervals will be rounded up with a warning.

The `"default"` profiling event is `"elapsed"` on Windows and `"cpu"` on Unix.

Support for `"elapsed"` event on Unix is new and considered experimental. To reduce the risk of missing a sample, R tries to use the (real-time) FIFO scheduling policy with the maximum scheduling priority for an internal thread which initiates collection of each sample. If setting that priority fails, it tries to use the maximum scheduling priority of the current scheduling policy, falling back to the current scheduling parameters. On Linux, regular users are typically not allowed to use the real-time scheduling priorities. This can be usually allowed via PAM (e.g. `/etc/security/limits.conf`), see the OS documentation for details. The priorities only matter when profiling a system under high load.

Functions will only be recorded in the profile log if they put a context on the call stack (see `sys.calls`). Some `primitive` functions do not do so: specifically those which are of `type "special"` (see the ‘R Internals’ manual for more details).

Individual statements will be recorded in the profile log if `line.profiling` is `TRUE`, and if the code being executed was parsed with source references. See `parse` for a discussion of source references. By default the statement locations are not shown in `summaryRprof`, but see that help page for options to enable the display.

## Filtering Out Call Frames

Lazy evaluation makes the call stack more complex because intervening call frames are created between the time arguments are applied to a function, and the time they are effectively evaluated. When the call stack is represented as a tree, these intervening frames appear as sibling nodes. For instance, evaluating `try(EXPR)` produces the following call tree, at the time `EXPR` gets evaluated:

```
1. +-base::try(EXPR)
2. | \-base::tryCatch(...)
3. |   \-base::tryCatchList(expr, classes, parentenv, handlers)
4. |     \-base::tryCatchOne(expr, names, parentenv, handlers[[1L]])
5. |       \-base::doTryCatch(return(expr), name, parentenv, handler)
6. \-EXPR
```

Lines 2 to 5 are intervening call frames, the last of which finally triggered evaluation of `EXPR`. Setting `filter.callframes` to `TRUE` simplifies the profiler output by removing all sibling nodes of intervening frames.

The same kind of call frame filtering is applied with `eval()` frames. When you call `eval()`, two frames are pushed on the stack to ensure a continuity between frames. Say we have these definitions:

```
calling <- function() evaluator(quote(called()), environment())
evaluator <- function(expr, env) eval(expr, env)
called <- function() EXPR()
```

`calling()` calls `called()` in its own environment, via `eval()`. The latter is called indirectly through `evaluator()`. The net effect of this code is identical to just calling `called()` directly, without the intermediaries. However, the full call stack looks like this:

```
1. calling()
2. \-evaluator(quote(called()), environment())
3.   \-base::eval(expr, env)
4.     \-base::eval(expr, env)
5.       \-called()
6.         \-EXPR()
```

When call frame filtering is turned on, the true calling environment of `called()` is looked up, and the filtered call stack looks like this:

```
1. calling()
5. \-called()
6.   \-EXPR()
```

If the calling environment is not on the stack, the function called by `eval()` becomes a root node. Say we have:

```
calling <- function() evaluator(quote(called()), new.env())
```

With call frame filtering we then get the following filtered call stack:

```
5. called()
6. \-EXPR()
```

## Note

**On Unix-alikes:** Profiling is not available on all platforms. By default, support for profiling is compiled in if possible – configure R with ‘--disable-R-profiling’ to change this.

As R CPU profiling uses the same mechanisms as C profiling, the two cannot be used together, so do not use `Rprof(event = "cpu")` (the default) in an executable built for C-level profiling (such as using the GCC option ‘-p’ or ‘-pg’).

**On Windows:** `filename` can be a UTF-8-encoded filepath that cannot be translated to the current locale.

The profiler interrupts R asynchronously, and it cannot allocate memory to store results as it runs. This affects line profiling, which needs to store an unknown number of file pathnames. The `numfiles` and `bufsize` arguments control the size of pre-allocated buffers to hold these results: the former counts the maximum number of paths, the latter counts the numbers of bytes in them. If the profiler runs out of space it will skip recording the line information for new files, and issue a warning when `Rprof(NULL)` is called to finish profiling.

[summaryRprof](#) to analyse the output file.

[tracemem](#), [Rprofmem](#) for other ways to track memory use.

**Examples**

```
## Not run: Rprof()
## some code to be profiled
Rprof(NULL)
## some code NOT to be profiled
Rprof(append = TRUE)
## some code to be profiled
Rprof(NULL)
## ...
## Now post-process the output as described in Details

## End(Not run)
```

---

Rprofmem

*Enable Profiling of R's Memory Use*

---

**Description**

Enable or disable reporting of memory allocation in R.

**Usage**

```
Rprofmem(filename = "Rprofmem.out", append = FALSE, threshold = 0)
```

**Arguments**

|           |  |
|-----------|--|
| filename  | The file to be used for recording the memory allocations. Set to NULL or "" to disable reporting.  |
| append    | logical: should the file be over-written or appended to?   |
| threshold | numeric: allocations on R's "large vector" heap larger than this number of bytes will be reported. |

**Details**

Enabling profiling automatically disables any existing profiling to another or the same file.

Profiling writes the call stack to the specified file every time `malloc` is called to allocate a large vector object or to allocate a page of memory for small objects. The size of a page of memory and the size above which `malloc` is used for vectors are compile-time constants, by default 2000 and 128 bytes respectively.

The profiler tracks allocations, some of which will be to previously used memory and will not increase the total memory use of R.

**Value**

None

**Note**

The memory profiler slows down R even when not in use, and so is a compile-time option. (It is enabled in a standard Windows build of R.)

The memory profiler can be used at the same time as other R and C profilers.

**See Also**

The R sampling profiler, [Rprof](#) also collects memory information.

[tracemem](#) traces duplications of specific objects.

The chapter on ‘Tidying and profiling R code’ in the ‘Writing R Extensions’ manual.

**Examples**

```
## Not run:
## not supported unless R is compiled to support it.
Rprofmem("Rprofmem.out", threshold = 1000)
example(glm)
Rprofmem(NULL)
noquote(readLines("Rprofmem.out", n = 5))

## End(Not run)
```

---

Rscript

---

*Scripting Front-End for R*

---

**Description**

This is an alternative front end for use in ‘#!’ scripts and other scripting applications.

**Usage**

```
Rscript [options] file [args]
Rscript [options] -e expr [-e expr2 ...] [args]
```

**Arguments**

|             |   |
|-------------|---|
| options     | a list of options, all beginning with ‘--’. These can be any of the options of the standard R front-end, and also those described in the details. |
| expr, expr2 | R expression(s), properly quoted.   |
| file        | the name of a file containing R commands. ‘-’ indicates ‘stdin’.  |
| args        | arguments to be passed to the script in file or expressions supplied via ‘-e’.  |

## Details

`Rscript --help` gives details of usage, and `Rscript --version` gives the version of `Rscript`.

Other invocations invoke the `R` front-end with selected options. This front-end is convenient for writing `#!/` scripts since it is an executable and takes `file` directly as an argument. Options `--no-echo --no-restore` are always supplied: these imply `--no-save`. Arguments that contain spaces cannot be specified directly on the `#!/` line, because spaces and tabs are interpreted as delimiters and there is no way to protect them from this interpretation on the `#!/` line. (The standard Windows command line has no concept of `#!/` scripts, but Cygwin shells do.)

*Either* one or more `-e` options or `file` should be supplied. When using `-e` options be aware of the quoting rules in the shell used: see the examples.

The prescribed order of arguments is important: e.g. `--verbose` specified after `-e` will be part of `args` and passed to the expression; the same will happen to `-e` specified after `file`.

Additional options accepted as part of options (before `file` or `-e`) are

`--verbose` gives details of what `Rscript` is doing.

`--default-packages=list` where `list` is a comma-separated list of package names or `NULL`. Sets the environment variable `R_DEFAULT_PACKAGES` which determines the packages loaded on startup.

Spaces are allowed in `expr` and `file` (but will need to be protected from the shell in use, if any, for example by enclosing the argument in quotes).

If `--default-packages` is not used, then `Rscript` checks the environment variable `R_SCRIPT_DEFAULT_PACKAGES`. If this is set, then it takes precedence over `R_DEFAULT_PACKAGES`.

Normally the version of `R` is determined at installation, but this can be overridden by setting the environment variable `RHOME`.

`stdin()` refers to the input file, and `file("stdin")` to the `stdin` file stream of the process.

## Note

`Rscript` is only supported on systems with the `execv` system call.

## Examples

```
## Not run:
Rscript -e 'date()' -e 'format(Sys.time(), "%a %b %d %X %Y")'

# Get the same initial packages in the same order as default R:
Rscript --default-packages=methods,datasets,utils,grDevices,graphics,stats -e 'sessionInfo()'

## example #! script for a Unix-alike
## (arguments given on the #! line end up as [options] to Rscript, while
## arguments passed to the #! script end up as [args], so available to
## commandArgs())
#!/path/to/Rscript --vanilla --default-packages=utils
args <- commandArgs(TRUE)
res <- try(install.packages(args))
if(inherits(res, "try-error")) q(status=1) else q()

## End(Not run)
```

---

RShowDoc

*Show R Manuals and Other Documentation*

---

## Description

Utility function to find and display R documentation.

## Usage

```
RShowDoc(what, type = c("pdf", "html", "txt"), package)
```

## Arguments

|                      |   |
|----------------------|---|
| <code>what</code>    | a character string: see ‘Details’.  |
| <code>type</code>    | an optional character string giving the preferred format. Can be abbreviated.                         |
| <code>package</code> | an optional character string specifying the name of a package within which to look for documentation. |

## Details

`what` can specify one of several different sources of documentation, including the R manuals (R-admin, R-data, R-exts, R-intro, R-ints, R-lang), NEWS, COPYING (the GPL licence), any of the licenses in ‘share/licenses’, FAQ (also available as R-FAQ), and the files in ‘[R\\_HOME](#)/doc’.

Only on Windows, the R for Windows FAQ is specified by `rw-FAQ`.

If `package` is supplied, documentation is looked for in the ‘doc’ and top-level directories of an installed package of that name.

If `what` is missing a brief usage message is printed.

The documentation types are tried in turn starting with the first specified in `type` (or “pdf” if none is specified).

## Value

A invisible character string given the path to the file found.

## See Also

For displaying regular help files, [help](#) (or [?](#)) and [help.start](#).

For `type = "txt"`, [file.show](#) is used. [vignettes](#) are nicely viewed via `RShowDoc(*, package=.)`.

## Examples

```
RShowDoc("R-lang")
RShowDoc("FAQ", type = "html")
RShowDoc("frame", package = "grid")
RShowDoc("changes.txt", package = "grid")
RShowDoc("NEWS", package = "MASS")
```

**Description**

Search for key words or phrases in various documentation, such as R manuals, help pages of base and CRAN packages, vignettes, task views and others, using the search engine at <https://search.r-project.org> and view them in a web browser.

**Usage**

```
RSiteSearch(string,
             restrict = c("functions", "descriptions", "news", "Rfunctions",
                           "Rmanuals", "READMEs", "views", "vignettes"),
             format,
             sortby = c("score", "date:late", "date:early", "subject",
                          "subject:descending", "size", "size:descending"),
             matchesPerPage = 20,
             words = c("all", "any"))
```

**Arguments**

|                             |  |
|-----------------------------|--|
| <code>string</code>         | A character string specifying word(s) or phrase(s) to search. If the words are to be searched as one entity, enclose them either in (escaped) quotes or in braces.   |
| <code>restrict</code>       | A character vector, typically of length greater than one. Values can be abbreviated. Possible areas to search in: <code>functions</code> for help pages of CRAN packages, <code>descriptions</code> for extended descriptions of CRAN packages, <code>news</code> for package NEWS, <code>Rfunctions</code> for help pages of R base packages, <code>Rmanuals</code> for R manuals, <code>READMEs</code> for ‘README’ files of CRAN packages, <code>views</code> for task views, <code>vignettes</code> for package vignettes. |
| <code>format</code>         | deprecated.  |
| <code>sortby</code>         | character string (can be abbreviated) indicating how to sort the search results: ( <code>score</code> , <code>date:late</code> for sorting by date with latest results first, <code>date:early</code> for earliest first, <code>subject</code> for captions in alphabetical order, <code>subject:descending</code> for reverse alphabetical order, <code>size</code> or <code>size:descending</code> for size.)  |
| <code>matchesPerPage</code> | How many items to show per page.   |
| <code>words</code>          | Show results matching all words/phrases (default) or any of them.  |

**Details**

This function is designed to work with the search site at <https://search.r-project.org>.

Unique partial matches will work for all arguments. Each new browser window will stay open unless you close it.

**Value**

(Invisibly) the complete URL passed to the browser, including the query string.

**Author(s)**

Andy Liaw and Jonathan Baron and Gennadiy Starostin

**See Also**

[help.search](#), [help.start](#) for local searches.

[browseURL](#) for how the help file is displayed.

**Examples**

```
# need Internet connection
## for phrase searching you may use (escaped) double quotes or brackets
RSiteSearch("{logistic regression} \"glm object\")
RSiteSearch('"logistic regression"')

## Search in vignettes and help files of R base packages
## store the query string:
fullquery <- RSiteSearch("lattice", restrict = c("vignettes", "Rfunctions"))
fullquery # a string of 112 characters
```

---

rtags

---

*An Etags-like Tagging Utility for R*

---

**Description**

rtags provides etags-like indexing capabilities for R code, using R's own parser.

**Usage**

```
rtags(path = ".", pattern = "\\.[RrSs]$",
      recursive = FALSE,
      src = list.files(path = path, pattern = pattern,
                      full.names = TRUE,
                      recursive = recursive),
      keep.re = NULL,
      ofile = "", append = FALSE,
      verbose = getOption("verbose"),
      type = c("etags", "ctags"))
```

**Arguments**

path, pattern, recursive

Arguments passed on to [list.files](#) to determine the files to be tagged. By default, these are all files with extension `‘.R’`, `‘.r’`, `‘.S’`, and `‘.s’` in the current directory. These arguments are ignored if `src` is specified.

src

A vector of file names to be indexed.

keep.re

A regular expression further restricting `src` (the files to be indexed). For example, specifying `keep.re = "/R/[^/]*\\.R$"` will only retain files with extension `‘.R’` inside a directory named `‘R’`.

|         |   |
|---------|---|
| ofile   | Passed on to <code>cat</code> as the <code>file</code> argument; typically the output file where the tags will be written ("TAGS" or "tags" by convention). By default, the output is written to the R console (unless redirected). |
| append  | Logical, indicating whether the output should overwrite an existing file, or append to it.  |
| verbose | Logical. If TRUE, file names are echoed to the R console as they are processed.   |
| type    | Character string specifying whether emacs style ("etags") or vi style ("ctags") tags are to be generated.   |

## Details

Many text editors allow definitions of functions and other language objects to be quickly and easily located in source files through a tagging utility. This functionality requires the relevant source files to be preprocessed, producing an index (or tag) file containing the names and their corresponding locations. There are multiple tag file formats, the most popular being the vi-style ctags format and the emacs-style etags format. Tag files in these formats are usually generated by the `ctags` and `etags` utilities respectively. Unfortunately, these programs do not recognize R code syntax. They do allow tagging of arbitrary language files through regular expressions, but this too is insufficient.

The `rtags` function is intended to be a tagging utility for R code. It parses R code files (using R's parser) and produces tags in both etags and ctags formats. The support for vi-style ctags is rudimentary, and was adapted from a patch by Neal Fultz; see [PR#17214](#).

It may be more convenient to use the command-line wrapper script `R CMD rtags`.

Rtangle

*R Driver for Stangle***Description**

A driver for [Stangle](#) that extracts R code chunks. Notably all `RtangleSetup()` arguments may be used as arguments in the `Stangle()` call.

**Usage**

```
Rtangle()
RtangleSetup(file, syntax, output = NULL, annotate = TRUE,
             split = FALSE, quiet = FALSE, drop.evalFALSE = FALSE, ...)
```

**Arguments**

|                             |  |
|-----------------------------|--|
| <code>file</code>           | name of Sweave source file. See the description of the corresponding argument of <a href="#">Sweave</a> .  |
| <code>syntax</code>         | an object of class <code>SweaveSyntax</code> .   |
| <code>output</code>         | name of output file used unless <code>split = TRUE</code> : see ‘Details’.   |
| <code>annotate</code>       | a logical or <a href="#">function</a> . When true, as by default, code chunks are separated by comment lines specifying the names and line numbers of the code chunks. If FALSE the decorating comments are omitted. Alternatively, <code>annotate</code> may be a function, see section ‘Chunk annotation’. |
| <code>split</code>          | split output into a file for each code chunk?  |
| <code>quiet</code>          | logical to suppress all progress messages.   |
| <code>drop.evalFALSE</code> | logical; When false, as by default, all chunks with option <code>eval = FALSE</code> are <i>commented out</i> in the output; otherwise ( <code>drop.evalFALSE = TRUE</code> ) they are omitted entirely.   |
| <code>...</code>            | additional named arguments setting defaults for further options listed in ‘Supported Options’.   |

**Details**

Unless `split = TRUE`, the default name of the output file is `basename(file)` with an extension corresponding to the Sweave syntax (e.g., ‘`Rnw`’, ‘`Stex`’) replaced by ‘`R`’. File names “`stdout`” and “`stderr`” are interpreted as the output and message connection respectively.

If splitting is selected (including by the options in the file), each chunk is written to a separate file with extension the name of the ‘engine’ (default ‘`.R`’).

Note that this driver does more than simply extract the code chunks verbatim, because chunks may re-use earlier chunks.

**Chunk annotation (`annotate`)**

By default `annotate = TRUE`, the annotation is of one of the forms

```
#####
### code chunk number 3: viewport
#####

#####
### code chunk number 18: grid.Rnw:647-648
#####

#####
### code chunk number 19: trellisdata (eval = FALSE)
#####
```

using either the chunk label (if present, i.e., when specified in the source) or the file name and line numbers.

`annotate` may be a function with formal arguments (`options`, `chunk`, `output`), e.g. to produce less dominant chunk annotations; see `Rtangle()$runcode` how it is called instead of the default.

### Supported Options

Rtangle supports the following options for code chunks (the values in parentheses show the default values):

**engine:** character string ("R"). Only chunks with `engine` equal to "R" or "S" are processed.

**keep.source:** logical (TRUE). If `keep.source == TRUE` the original source is copied to the file. Otherwise, deparsed source is output.

**eval:** logical (TRUE). If FALSE, the code chunk is copied across but commented out.

**prefix** Used if `split = TRUE`. See `prefix.string`.

**prefix.string:** a character string, default is the name of the source file (without extension). Used if `split = TRUE` as the prefix for the filename if the chunk has no label, or if it has a label and `prefix = TRUE`. Note that this is used as part of filenames, so needs to be portable.

**show.line.nos** logical (FALSE). Should the output be annotated with comments showing the line number of the first code line of the chunk?

[Sweave](#), [RweaveLatex](#)

### Examples

```
nmRnw <- "example-1.Rnw"
exfile <- system.file("Sweave", nmRnw, package = "utils")
## Create R source file
Stangle(exfile)
nmR <- sub("Rnw$", "R", nmRnw) # the (default) R output file name
if(interactive()) file.show("example-1.R")
```

```
## Smaller R source file with custom annotation:
my.Ann <- function(options, chunk, output) {
  cat("### chunk #", options$chunknr, ": ",
      if(!is.null(ol <- options$label)) ol else .RtangleCodeLabel(chunk),
      if(!options$eval) " (eval = FALSE)", "\n",
      file = output, sep = "")
}
Stangle(exfile, annotate = my.Ann)
if(interactive()) file.show("example-1.R")

Stangle(exfile, annotate = my.Ann, drop.evalFALSE=TRUE)
if(interactive()) file.show("example-1.R")
```

RweaveLatex

*R/LaTeX Driver for Sweave*

## Description

A driver for [Sweave](#) that translates R code chunks in  $\text{\LaTeX}$  files by “running them”, i.e., `parse()` and `eval()` each.

## Usage

```
RweaveLatex()
```

```
RweaveLatexSetup(file, syntax, output = NULL, quiet = FALSE,
                  debug = FALSE, stylepath, ...)
```

## Arguments

|                        |  |
|------------------------|--|
| <code>file</code>      | Name of Sweave source file. See the description of the corresponding argument of <a href="#">Sweave</a> .  |
| <code>syntax</code>    | An object of class <code>SweaveSyntax</code> .   |
| <code>output</code>    | Name of output file. The default is to remove extension <code>‘.nw’</code> , <code>‘.Rnw’</code> or <code>‘.Snw’</code> and to add extension <code>‘.tex’</code> . Any directory paths in <code>file</code> are also removed such that the output is created in the current working directory. |
| <code>quiet</code>     | If <code>TRUE</code> all progress messages are suppressed.   |
| <code>debug</code>     | If <code>TRUE</code> , input and output of all code chunks is copied to the console.   |
| <code>stylepath</code> | See ‘Details’.   |
| <code>...</code>       | named values for the options listed in ‘Supported Options’.  |

## Details

The  $\text{\LaTeX}$  file generated needs to contain the line `‘\usepackage{Sweave}’`, and if this is not present in the Sweave source file (possibly in a comment), it is inserted by the `RweaveLatex` driver as last line before the `‘\begin{document}’` statement. If `stylepath = TRUE`, a hard-coded path to the file `‘Sweave.sty’` in the R installation is set in place of `Sweave`. The hard-coded path makes the  $\text{\LaTeX}$  file less portable, but avoids the problem of installing the current version of `‘Sweave.sty’` to some place in your TeX input path. However, TeX may not be able to process the hard-coded path if it contains spaces (as it often will under Windows) or TeX special characters.

The default for `stylepath` is now taken from the environment variable `SWEAVE_STYLEPATH_DEFAULT`, or is `FALSE` if that is unset or empty. If set, it should be exactly `TRUE` or `FALSE`; any other values are taken as `FALSE`.

The simplest way for frequent Sweave users to ensure that `'Sweave.sty'` is in the TeX input path is to add `'R_HOME/share/texmf'` as a 'texmf tree' ('root directory' in the parlance of the 'MiKTeX settings' utility).

By default, `'Sweave.sty'` loads the `'graphicx'` L<sup>A</sup>T<sub>E</sub>X package and sets the width of all included graphics to:

```
\setkeys{Gin}{width=0.8\textwidth}'
```

This setting (defined in the `'graphicx'` package) affects the `width` size option passed to the `'\includegraphics{...}'` directive for each plot file and in turn impacts the scaling of your plot files as they will appear in your final document.

Thus, for example, you may set `width=3` in your figure chunk and the generated graphics files will be set to 3 inches in width. However, the width of your graphic in your final document will be set to `0.8\textwidth` and the height dimension will be scaled accordingly. Fonts and symbols will be similarly scaled in the final document.

You can adjust the default value by including the `'\setkeys{Gin}{width=...}'` directive in your `'.Rnw'` file after the `'\begin{document}'` directive and changing the `width` option value as you prefer, using standard L<sup>A</sup>T<sub>E</sub>X measurement values.

If you wish to override this default behavior entirely, you can add a `'\usepackage[nogin]{Sweave}'` directive in your preamble. In this case, no size/scaling options will be passed to the `'\includegraphics{...}'` directive and the `height` and `width` options will determine both the runtime generated graphic file sizes and the size of the graphics in your final document.

`'Sweave.sty'` also supports the `'[nofontenc]'` option, which skips the default inclusion of `'\usepackage[T1]{fontenc}'` for pdfTeX processing.

It also supports the `'[inconsolata]'` option, to render monospaced text in `inconsolata`, the font used by default for R help pages.

The use of fancy quotes (see [sQuote](#)) can cause problems when setting R output in non-UTF-8 locales (note that pdfTeX assumes UTF-8 by default since 2018). Either set `options(useFancyQuotes = FALSE)` or arrange that L<sup>A</sup>T<sub>E</sub>X is aware of the encoding used and ensure that typewriter fonts containing directional quotes are used.

Some L<sup>A</sup>T<sub>E</sub>X graphics drivers do not include `'.png'` or `'.jpg'` in the list of known extensions. To enable them, add something like `'\DeclareGraphicsExtensions{.png,.pdf,.jpg}'` to the preamble of your document or check the behavior of your graphics driver. When both `pdf` and `png` are `TRUE` both files will be produced by Sweave, and their order in the `'DeclareGraphicsExtensions'` list determines which will be used by pdf<sub>l</sub>atex.

## Supported Options

RweaveLatex supports the following options for code chunks (the values in parentheses show the default values). Character string values should be quoted when passed from Sweave through ... but not when used in the header of a code chunk.

**engine:** character string ("R"). Only chunks with `engine` equal to "R" or "S" are processed.

**echo:** logical (TRUE). Include R code in the output file?

**keep.source:** logical (TRUE). When echoing, if `TRUE` the original source is copied to the file. Otherwise, deparsed source is echoed.

**eval:** logical (TRUE). If FALSE, the code chunk is not evaluated, and hence no text nor graphical output produced.

**results:** character string ("verbatim"). If "verbatim", the output of R commands is included in the verbatim-like 'Soutput' environment. If "tex", the output is taken to be already proper L<sup>A</sup>T<sub>E</sub>X markup and included as is. If "hide" then all output is completely suppressed (but the code executed during the weave). Values can be abbreviated.

**print:** logical (FALSE). If TRUE, this forces auto-printing of all expressions.

**term:** logical (TRUE). If TRUE, visibility of values emulates an interactive R session: values of assignments are not printed, values of single objects are printed. If FALSE, output comes only from explicit `print` or similar statements.

**split:** logical (FALSE). If TRUE, text output is written to separate files for each code chunk.

**strip.white:** character string ("true"). If "true", blank lines at the beginning and end of output are removed. If "all", then all blank lines are removed from the output. If "false" then blank lines are retained.

A 'blank line' is one that is empty or includes only whitespace (spaces and tabs).

Note that blank lines in a code chunk will usually produce a prompt string rather than a blank line on output.

**prefix:** logical (TRUE). If TRUE generated filenames of figures and output all have the common prefix given by the `prefix.string` option: otherwise only unlabelled chunks use the prefix.

**prefix.string:** a character string, default is the name of the source file (without extension). Note that this is used as part of filenames, so needs to be portable.

**include:** logical (TRUE), indicating whether input statements for text output (if `split = TRUE`) and '`\includegraphics`' statements for figures should be auto-generated. Use `include = FALSE` if the output should appear in a different place than the code chunk (by placing the input line manually).

**fig:** logical (FALSE), indicating whether the code chunk produces graphical output. Note that only one figure per code chunk can be processed this way. The labels for figure chunks are used as part of the file names, so should preferably be alphanumeric.

**eps:** logical (FALSE), indicating whether EPS figures should be generated. Ignored if `fig = FALSE`.

**pdf:** logical (TRUE), indicating whether PDF figures should be generated. Ignored if `fig = FALSE`.

**pdf.version, pdf.encoding, pdf.compress:** passed to `pdf` to set the version, encoding and compression (or not). Defaults taken from `pdf.options()`.

**png:** logical (FALSE), indicating whether PNG figures should be generated. Ignored if `fig = FALSE`. Only available in R  $\geq 2.13.0$ .

**jpeg:** logical (FALSE), indicating whether JPEG figures should be generated. Ignored if `fig = FALSE`. Only available in R  $\geq 2.13.0$ .

**grdevice:** character (NULL): see section 'Custom Graphics Devices'. Ignored if `fig = FALSE`. Only available in R  $\geq 2.13.0$ .

**width:** numeric (6), width of figures in inches. See 'Details'.

**height:** numeric (6), height of figures in inches. See 'Details'.

**resolution:** numeric (300), resolution in pixels per inch: used for PNG and JPEG graphics. Note that the default is a fairly high value, appropriate for high-quality plots. Something like 100 is a better choice for package vignettes.

**concordance:** logical (FALSE). Write a concordance file to link the input line numbers to the output line numbers.

**figs.only:** logical (FALSE). By default each figure chunk is run once, then re-run for each selected type of graphics. That will open a default graphics device for the first figure chunk and use that device for the first evaluation of all subsequent chunks. If this option is true, the figure chunk is run only for each selected type of graphics, for which a new graphics device is opened and then closed.

In addition, users can specify further options, either in the header of an individual code section or in a `\SweaveOpts{}` line in the document. For unknown options, their type is set at first use.

## Custom Graphics Devices

If option `grdevice` is supplied for a code chunk with both `fig` and `eval` true, the following call is made

```
get(options$grdevice, envir = .GlobalEnv)(name=, width=,
                                           height=, options)
```

which should open a graphics device. The chunk's code is then evaluated and `dev.off` is called. Normally a function of the name given will have been defined earlier in the Sweave document, e.g.

```
<<results=hide>>=
my.Swd <- function(name, width, height, ...)
  grDevices::png(filename = paste(name, "png", sep = "."),
                 width = width, height = height, res = 100,
                 units = "in", type = "quartz", bg = "transparent")
@
```

Alternatively for R >= 3.4.0, if the function exists in a package (rather than the `.GlobalEnv`) it can be used by setting `grdevice = "pkg::my.Swd"` (or with `:::` instead of `::` if the function is not exported).

Currently only one custom device can be used for each chunk, but different devices can be used for different chunks.

A replacement for `dev.off` can be provided as a function with suffix `.off`, e.g. `my.Swd.off()` or `pkg::my.Swd.off()`, respectively.

## Hook Functions

Before each code chunk is evaluated, zero or more hook functions can be executed. If `getOption("SweaveHooks")` is set, it is taken to be a named list of hook functions. For each *logical* option of a code chunk (`echo`, `print`, ...) a hook can be specified, which is executed if and only if the respective option is TRUE. Hooks must be named elements of the list returned by `getOption("SweaveHooks")` and be functions taking no arguments. E.g., if option "SweaveHooks" is defined as `list(fig = foo)`, and `foo` is a function, then it would be executed before the code in each figure chunk. This is especially useful to set defaults for the graphical parameters in a series of figure chunks.

Note that the user is free to define new Sweave logical options and associate arbitrary hooks with them. E.g., one could define a hook function for a new option called `clean` that removes all objects in the workspace. Then all code chunks specified with `clean = TRUE` would start operating on an empty workspace.

Rwin configuration *R for Windows Configuration*

---

**Description**

The file ‘Rconsole’ configures the R GUI (Rgui) console under MS Windows and `loadRconsole(*)` loads a new configuration.

The file ‘Rdevga’ configures the graphics devices `windows`, `win.graph`, `win.metafile` and `win.print`, as well as the bitmap devices `bmp`, `jpeg`, `png` and `tiff` (which use for type = "windows" use windows internally).

**Usage**

```
loadRconsole(file)
```

**Arguments**

|                   |  |
|-------------------|--|
| <code>file</code> | The file from which to load a new ‘Rconsole’ configuration. By default a file dialog is used to select a file. |
|-------------------|--|

**Details**

There are system copies of these files in ‘[R\\_HOME](#)\etc’. Users can have personal copies of the files: these are looked for in the location given by the environment variable `R_USER`. The system files are read only if a corresponding personal file is not found.

If the environment variable `R_USER` is not set, the R system sets it to `HOME` if that is set (stripping any trailing slash), otherwise to the Windows ‘personal’ directory, otherwise to `{HOMEDRIVE}{HOMEPATH}` if `HOMEDRIVE` and `HOMEPATH` are both set otherwise to the working directory. This is as described in the file ‘`rw-FAQ`’.

**Value**

Each of the files contains details in its comments of how to set the values.

At the time of writing ‘Rdevga’ configured the mapping of font numbers to fonts, and ‘Rconsole’ configured the appearance (single or multiple document interface, toolbar, status bar on MDI), size, font and colours of the GUI console, and whether resizing the console sets `options("width")`.

The file ‘Rconsole’ also configures the internal pager. This shares the font and colours of the console, but can be sized separately.

‘Rconsole’ can also set the initial positions of the console and the graphics device, as well as the size and position of the MDI workspace in MDI mode.

`loadRconsole` is called for its side effect of loading new defaults. It returns no useful value.

**Chinese/Japanese/Korean**

Users of these languages will need to select a suitable font for the console (perhaps MS Mincho) and for the graphics device (although the default `Arial` has many East Asian characters). It is essential that the font selected for the console has double-width East Asian characters – many monospaced fonts do not.

**Note**

The `GUI preferences` item on the `Edit` menu brings up an dialog box which can be used to edit the console settings, and to save them to a file.

This is only available on Windows.

[windows](#)

**Examples**

```
if(.Platform$OS.type == "windows") withAutoprint({
  ruser <- Sys.getenv("R_USER")
  cat("\n\nLocation for personal configuration files is\n    R_USER = ",
      ruser, "\n\n", sep = "")
  ## see if there are personal configuration files
  file.exists(file.path(ruser, c("Rconsole", "Rdevga")))

  ## show the configuration files used
  showConfig <- function(file)
  {
    ruser <- Sys.getenv("R_USER")
    path <- file.path(ruser, file)
    if(!file.exists(path)) path <- file.path(R.home(), "etc", file)
    file.show(path, header = path)
  }
  showConfig("Rconsole")
})
```

---

 savehistory

---

*Load or Save or Display the Commands History*

---

**Description**

Load or save or display the commands history.

**Usage**

```
loadhistory(file = ".Rhistory")
savehistory(file = ".Rhistory")

history(max.show = 25, reverse = FALSE, pattern, ...)

timestamp(stamp = date(),
          prefix = "##----- ", suffix = " -----##",
          quiet = FALSE)
```

**Arguments**

|                       |   |
|-----------------------|---|
| <code>file</code>     | The name of the file in which to save the history, or from which to load it. The path is relative to the current working directory. |
| <code>max.show</code> | The maximum number of lines to show. <code>Inf</code> will give all of the currently available history.                             |
| <code>reverse</code>  | logical. If true, the lines are shown in reverse order. Note: this is not useful when there are continuation lines.                 |
| <code>pattern</code>  | A character string to be matched against the lines of the history. When supplied, only <i>unique</i> matching lines are shown.      |
| <code>...</code>      | Arguments to be passed to <a href="#">grep</a> when doing the matching.   |
| <code>stamp</code>    | A value or vector of values to be written into the history.   |
| <code>prefix</code>   | A prefix to apply to each line.   |
| <code>suffix</code>   | A suffix to apply to each line.   |
| <code>quiet</code>    | If TRUE, suppress printing timestamp to the console.  |

**Details**

There are several history mechanisms available for the different R consoles, which work in similar but not identical ways. Notably, there are different implementations for Unix and Windows.

**Windows:** The functions described here work in `Rgui` and interactive `Rterm` but not in batch use of `Rterm` nor in embedded/DCOM versions.

**Unix-alikes:** The functions described here work under the `readline` command-line interface but may not otherwise (for example, in batch use or in an embedded application). Note that R can be built without `readline`.

`R.app`, the console on macOS, has a separate and largely incompatible history mechanism, which by default uses a file `‘.Rapp.history’` and saves up to 250 entries. These functions are not currently implemented there.

The (`readline` on Unix-alikes) history mechanism is controlled by two environment variables: `R_HISTSIZE` controls the number of lines that are saved (default 512), and `R_HISTFILE` (default `‘.Rhistory’`) sets the filename used for the loading/saving of history if requested at the beginning/end of a session (but not the default for `loadhistory/savehistory`). There is no limit on the number of lines of history retained during a session, so setting `R_HISTSIZE` to a large value has no penalty unless a large file is actually generated.

These environment variables are read at the time of saving, so can be altered within a session by the use of [Sys.setenv](#).

On Unix-alikes: Note that `readline` history library saves files with permission `0600`, that is with read/write permission for the user and not even read permission for any other account.

The `timestamp` function writes a timestamp (or other message) into the history and echos it to the console. On platforms that do not support a history mechanism only the console message is printed.

### Note

If you want to save the history at the end of (almost) every interactive session (even those in which you do not save the workspace), you can put a call to `savehistory()` in `.Last`. See the examples.

### Examples

```
## Not run:
## Save the history in the home directory: note that it is not
## (by default) read from there but from the current directory
.Last <- function()
  if(interactive()) try(savehistory("~/Rhistory"))

## End(Not run)
```

---

select.list

*Select Items from a List*

---

### Description

Select item(s) from a character vector.

### Usage

```
select.list(choices, preselect = NULL, multiple = FALSE,
            title = NULL, graphics = getOption("menu.graphics"))
```

### Arguments

|                        |   |
|------------------------|---|
| <code>choices</code>   | a character vector of items.  |
| <code>preselect</code> | a character vector, or <code>NULL</code> . If non-null and if the string(s) appear in the list, the item(s) are selected initially. |
| <code>multiple</code>  | logical: can more than one item be selected?  |
| <code>title</code>     | optional character string for window title, or <code>NULL</code> for no title.  |
| <code>graphics</code>  | logical: should a graphical widget be used?   |

### Details

The normal default is `graphics = TRUE`.

**On Windows**, this brings up a modal dialog box with a (scrollable) list of items, which can be selected by the mouse. If `multiple` is true, further items can be selected or deselected by holding the control key down whilst selecting, and shift-clicking can be used to select ranges. Normal termination is via the ‘OK’ button or by hitting Enter or double-clicking an item. Selection can be aborted via the ‘Cancel’ button or pressing Escape.

**Under the macOS GUI**, this brings up a modal dialog box with a (scrollable) list of items, which can be selected by the mouse.

**On other Unix-like platforms** it will use a Tcl/Tk listbox widget if possible.

If `graphics` is `FALSE` or no graphical widget is available it displays a text list from which the user can choose by number(s). The `multiple = FALSE` case uses `menu`. Preselection is only supported for `multiple = TRUE`, where it is indicated by a "+" preceding the item.

It is an error to use `select.list` in a non-interactive session.

### Value

A character vector of selected items. If `multiple` is false and no item was selected (or `Cancel` was used), "" is returned. If `multiple` is true and no item was selected (or `Cancel` was used) then a character vector of length 0 is returned.

### See Also

`menu`, `tk_select.list` for a graphical version using Tcl/Tk.

### Examples

```
## Not run:
select.list(sort(.packages(all.available = TRUE)))

## End(Not run)
```

---

sessionInfo

*Collect Information About the Current R Session*

---

### Description

Get and report version information about R, the OS and attached or loaded packages.

The `print()` and `toLatex()` methods (for a "sessionInfo" object) show the locale and timezone information by default, when `locale` or `tzone` are true. The `system.codepage` is only shown when it is not empty, i.e., only on Windows, *and* if it differs from `code.page`, see below or `l10n_info()`.

### Usage

```
sessionInfo(package = NULL)
## S3 method for class 'sessionInfo'
print(x, locale = TRUE, tzone = locale,
      RNG = !identical(x$RNGkind, .RNGdefaults), ...)
## S3 method for class 'sessionInfo'
toLatex(object, locale = TRUE, tzone = locale,
        RNG = !identical(object$RNGkind, .RNGdefaults), ...)
osVersion
```

**Arguments**

|         |  |
|---------|--|
| package | a character vector naming installed packages, or <code>NULL</code> (the default) meaning all attached packages.  |
| x       | an object of class <code>"sessionInfo"</code> .  |
| object  | an object of class <code>"sessionInfo"</code> .  |
| locale  | show locale, by default <code>tzzone</code> , and (on Windows) code page information?  |
| tzzone  | show time zone information?  |
| RNG     | show information on <code>RNGkind()</code> ? Defaults to <code>true</code> iff it differs from the R version's default, i.e., <code>RNGversion(*)</code> . |
| ...     | currently not used.  |

**Value**

`sessionInfo()` returns an object of class `"sessionInfo"` which has `print` and `toLatex` methods. This is a list with components

|                          |  |
|--------------------------|--|
| <code>R.version</code>   | a list, the result of calling <code>R.Version()</code> .   |
| <code>platform</code>    | a character string describing the platform R was built under. Where sub-architectures are in use this is of the form 'platform/sub-arch': 32-bit builds have (32-bit) appended |
| <code>running</code>     | a character string (or possibly <code>NULL</code> ), the same as <code>osVersion</code> , see below.   |
| <code>RNGkind</code>     | a character vector, the result of calling <code>RNGkind()</code> .   |
| <code>matprod</code>     | a character string, the result of calling <code>getOption("matprod")</code> .  |
| <code>BLAS</code>        | a character string, the result of calling <code>extSoftVersion()["BLAS"]</code> .  |
| <code>LAPACK</code>      | a character string, the result of calling <code>La_library()</code> .  |
| <code>LA_version</code>  | a character string, the result of calling <code>La_version()</code> .  |
| <code>locale</code>      | a character string, the result of calling <code>Sys.getlocale()</code> .   |
| <code>tzzone</code>      | a character string, the result of calling <code>Sys.timezone()</code> .  |
| <code>tzcode_type</code> | a character string indicating source (system/internal) of the date-time conversion and printing functions.   |
| <code>basePkgs</code>    | a character vector of base packages which are attached.  |
| <code>otherPkgs</code>   | (not always present): a named list of the results of calling <code>packageDescription</code> on other attached packages.   |
| <code>loadedOnly</code>  | (not always present): a named list of the results of calling <code>packageDescription</code> on packages whose namespaces are loaded but are not attached.                     |

**osVersion**

`osVersion` is a character string (or possibly `NULL` on bizarre platforms) describing the OS and version which it is running under (as distinct from built under). This attempts to name a Linux distribution and give the OS name on an Apple Mac.

It is the same as `sessionInfo()$running` and created when loading the **utils** package.

Windows may report unexpected versions: see the help for `win.version`.

How OSes identify themselves and their versions can be arcane: where possible `osVersion` (and hence `sessionInfo()$running`) uses a human-readable form.

Where R was compiled under macOS 10.x (as the CRAN Intel distributions were prior to R 4.3.0) but running under 'Big Sur' or later, macOS reports itself as '10.16' (which R recognizes as 'Big Sur ...') and not '11', '12', ....

**Note**

The information on ‘loaded’ packages and namespaces is the *current* version installed at the location the package was loaded from: it can be wrong if another process has been changing packages during the session.

**See Also**

[R.version](#), [R\\_compiled\\_by](#)

**Examples**

```
sI <- sessionInfo()
sI
# The same, showing the RNGkind, but not the locale :
print(sI, RNG = TRUE, locale = FALSE)
toLatex(sI, locale = FALSE) # shortest; possibly desirable at end of report
```

---

|                 |                                    |
|-----------------|------------------------------------|
| setRepositories | <i>Select Package Repositories</i> |
|-----------------|------------------------------------|

---

**Description**

Interact with the user to choose the package repositories to be used.

**Usage**

```
setRepositories(graphics = getOption("menu.graphics"),
               ind = NULL, addURLs = character(), name = NULL)
```

**Arguments**

|          |  |
|----------|--|
| graphics | Logical. If true, use a graphical list: on Windows or macOS GUI use a list box, and on a Unix-alike if <b>tk</b> and an X server are available, use Tk widget. Otherwise use a text <a href="#">menu</a> . |
| ind      | NULL or a vector of integer indices, which have the same effect as if they were entered at the prompt for graphics = FALSE.  |
| name     | NULL or character vector of names of the repositories in the repository table which has the same effect as passing the corresponding indices to ind.   |
| addURLs  | A character vector of additional URLs: it is often helpful to use a named vector.  |

**Details**

The default list of known repositories is stored in the file ‘[R\\_HOME](#)/etc/repositories’. That file can be edited for a site, or a user can have a personal copy in the file pointed to by the environment variable R\_REPOSITORIES, or if this is unset, NULL or does not exist, in ‘[HOME](#)/.R/repositories’, which will take precedence.

A Bioconductor mirror can be selected by setting [options](#)("BioC\_mirror"), e.g. via [chooseBioCmirror](#) — the default value is “<https://bioconductor.org>”. This version of R chooses Bioconductor version 3.20 by default, but that can be changed via the environment variable R\_BIOC\_VERSION.

The items that are preselected are those that are currently in `options("repos")` plus those marked as default in the list of known repositories.

The list of repositories offered depends on the setting of option `"pkgType"` as some repositories only offer a subset of types (e.g., only source packages or not macOS binary packages). Further, for binary packages some repositories (notably R-Forge) only offer packages for the current or recent versions of R. (Type `"both"` is equivalent to `"source"`.)

Repository 'CRAN' is treated specially: the value is taken from the current setting of `getOption("repos")` if this has an element `"CRAN"`: this ensures mirror selection is sticky.

This function requires the R session to be interactive unless `ind` or `name` is supplied. The latter overrides the former if both are supplied and values are not case-sensitive. If any of the supplied names does not match, an error is raised.

### Value

This function is invoked mainly for its side effect of updating `options("repos")`. It returns (invisibly) the previous `repos` options setting (as a [list](#) with component `repos`) or `NULL` if no changes were applied.

### Note

This does **not** set the list of repositories at startup: to do so set `options(repos =)` in a start up file (see help topic [Startup](#)) or via a customized 'repositories' file.

### See Also

[chooseCRANmirror](#), [chooseBioCmirror](#), [install.packages](#).

### Examples

```
## Not run:
setRepositories(addURLs =
  c(CRANxtras = "https://www.stats.ox.ac.uk/pub/RWin"))

## End(Not run)
oldrepos <- setRepositories(name = c("CRAN", "R-Forge"))
getOption("repos")
options(oldrepos) # restore
```

---

setWindowTitle

*Set the Window Title or the Status Bar of the RGui in Windows*

---

### Description

Set or get the title of the R (i.e. RGui) window which will appear in the task bar, or set the status bar (if in use).

**Usage**

```
setWindowTitle(suffix, title = paste(getIdentification(), suffix))

getWindowTitle()

getIdentification()

setStatusBar(text)
```

**Arguments**

|                     |  |
|---------------------|--|
| <code>suffix</code> | a character string to form part of the title                                   |
| <code>title</code>  | a character string forming the complete new title                              |
| <code>text</code>   | a character string of up to 255 characters, to be displayed in the status bar. |

**Details**

`setWindowTitle` appends `suffix` to the normal window identification (RGui, R Console or Rterm). Use `suffix = ""` to reset the title.

`getWindowTitle` gets the current title.

This sets the title of the frame in MDI mode, the title of the console for RGui `--sdi`, and the title of the window from which it was launched for Rterm. It has no effect in embedded uses of R.

`getIdentification` returns the normal window identification.

`setStatusBar` sets the text in the status bar of an MDI frame: if this is not currently shown it is selected and shown.

**Value**

The first three functions return a length 1 character vector.

`setWindowTitle` returns the previous window title (invisibly).

`getWindowTitle` and `getIdentification` return the current window title and the normal window identification, respectively.

**Note**

These functions are only available on Windows and only make sense when using the Rgui. E.g., in Rterm (and hence in ESS) the title is not visible (but can be set and gotten), and in a version of RStudio it has been "", invariably.

**Examples**

```
if(.Platform$OS.type == "windows") withAutoprint({
  ## show the current working directory in the title, saving the old one
  oldtitle <- setWindowTitle(getwd())
  Sys.sleep(0.5)
  ## reset the title
  setWindowTitle("")
  Sys.sleep(0.5)
  ## restore the original title
  setWindowTitle(title = oldtitle)
})
```

SHLIB

*Build Shared Object/DLL for Dynamic Loading***Description**

Compile the given source files and then link all specified object files into a shared object aka DLL which can be loaded into R using `dyn.load` or `library.dynam`.

**Usage**

```
R CMD SHLIB [options] [-o dllname] files
```

**Arguments**

|                      |  |
|----------------------|--|
| <code>files</code>   | a list specifying the object files to be included in the shared object/DLL. You can also include the name of source files (for which the object files are automatically made from their sources) and library linking commands.                         |
| <code>dllname</code> | the full name of the shared object/DLL to be built, including the extension (typically <code>.so</code> on Unix systems, and <code>.dll</code> on Windows). If not given, the basename of the object/DLL is taken from the basename of the first file. |
| <code>options</code> | Further options to control the processing. Use <code>R CMD SHLIB --help</code> for a current list.   |

**Details**

`R CMD SHLIB` is the mechanism used by [INSTALL](#) to compile source code in packages. It will generate suitable compilation commands for C, C++, Objective C(++) and Fortran sources: Fortran 90/95 sources can also be used but it may not be possible to mix these with other languages (on most platforms it is possible to mix with C, but mixing with C++ rarely works).

Please consult section ‘Creating shared objects’ in the manual ‘Writing R Extensions’ for how to customize it (for example to add `cpp` flags and to add libraries to the link step) and for details of some of its quirks.

Items in `files` with extensions `.c`, `.cpp`, `.cc`, `.C`, `.f`, `.f90`, `.f95`, `.m` (Objective-C), `.M` and `.mm` (Objective-C++) are regarded as source files, and those with extension `.o` as object files. All other items are passed to the linker.

Objective C(++) support is optional when R was configured: their main usage is on macOS.

Note that the appropriate run-time libraries will be used when linking if C++, Fortran or Objective C(++) sources are supplied, but not for compiled object files from these languages.

Option `-n` (also known as `--dry-run`) will show the commands that would be run without actually executing them.

**Note**

Some binary distributions of R have SHLIB in a separate bundle, e.g., an R-devel RPM.

**See Also**

[COMPILE](#), `dyn.load`, `library.dynam`.

The ‘R Installation and Administration’ and ‘Writing R Extensions’ manuals, including the section on ‘Customizing package compilation’ in the former.

**Examples**

```
## Not run:
# To link against a library not on the system library paths:
R CMD SHLIB -o mylib.so a.f b.f -L/opt/acml3.5.0/gnu64/lib -lacml

## End(Not run)
```

---

shortPathName

*Express File Paths in Short Form on Windows*

---

**Description**

Convert file paths to the short form. This is an interface to the Windows API call GetShortPathNameW.

**Usage**

```
shortPathName(path)
```

**Arguments**

path                      character vector of file paths.

**Details**

For most file systems, the short form is the ‘DOS’ form with 8+3 path components and no spaces, and this used to be guaranteed. But some file systems on recent versions of Windows do not have short path names when the long-name path will be returned instead.

**Value**

A character vector. The path separator will be ‘\’. If a file path does not exist, the supplied path will be returned with slashes replaced by backslashes.

**Note**

This is only available on Windows.

**See Also**

[normalizePath](#).

**Examples**

```
if(.Platform$OS.type == "windows") withAutoprint({
  cat(shortPathName(c(R.home(), tempdir())), sep = "\n")
})
```

## Description

These functions extract information from source references.

## Usage

```

getSrcFilename(x, full.names = FALSE, unique = TRUE)
getSrcDirectory(x, unique = TRUE)
getSrcCref(x)
getSrcLocation(x, which = c("line", "column", "byte", "parse"),
               first = TRUE)

```

## Arguments

|                         |  |
|-------------------------|--|
| <code>x</code>          | An object (typically a function) containing source references.   |
| <code>full.names</code> | Whether to include the full path in the filename result.         |
| <code>unique</code>     | Whether to list only unique filenames/directories.               |
| <code>which</code>      | Which part of a source reference to extract. Can be abbreviated. |
| <code>first</code>      | Whether to show the first (or last) location of the object.      |

## Details

Each statement of a function will have its own source reference if the `"keep.source"` option is `TRUE`. These functions retrieve all of them.

The components are as follows:

**line** The line number where the object starts or ends.

**column** The column number where the object starts or ends. Horizontal tabs are converted to spaces.

**byte** As for `"column"`, but counting bytes, which may differ in case of multibyte characters (and horizontal tabs).

**parse** As for `"line"`, but this ignores `#line` directives.

## Value

`getSrcFilename` and `getSrcDirectory` return character vectors holding the file-name/directory.

`getSrcCref` returns a list of `"srcCref"` objects or `NULL` if there are none.

`getSrcLocation` returns an integer vector of the requested type of locations.

## See Also

[srcCref](#), [getParseData](#)

## Examples

```
fn <- function(x) {
  x + 1 # A comment, kept as part of the source
}

# Show the temporary file directory
# where the example was saved

getSrcDirectory(fn)
getSrcLocation(fn, "line")
```

---

stack

---

*Stack or Unstack Vectors from a Data Frame or List*

---

## Description

Stacking vectors concatenates multiple vectors into a single vector along with a factor indicating where each observation originated. Unstacking reverses this operation.

## Usage

```
stack(x, ...)
## Default S3 method:
stack(x, drop=FALSE, ...)
## S3 method for class 'data.frame'
stack(x, select, drop=FALSE, ...)

unstack(x, ...)
## Default S3 method:
unstack(x, form, ...)
## S3 method for class 'data.frame'
unstack(x, form, ...)
```

## Arguments

|        |  |
|--------|--|
| x      | a list or data frame to be stacked or unstacked.   |
| select | an expression, indicating which variable(s) to select from a data frame.   |
| form   | a two-sided formula whose left side evaluates to the vector to be unstacked and whose right side evaluates to the indicator of the groups to create. Defaults to <code>formula(x)</code> in the data frame method for <code>unstack</code> . |
| drop   | Whether to drop the unused levels from the “ind” column of the return value.   |
| ...    | further arguments passed to or from other methods.   |

## Details

The `stack` function is used to transform data available as separate columns in a data frame or list into a single column that can be used in an analysis of variance model or other linear model. The `unstack` function reverses this operation.

Note that `stack` applies to *vectors* (as determined by `is.vector`): non-vector columns (e.g., factors) will be ignored with a warning. Where vectors of different types are selected they are concatenated by `unlist` whose help page explains how the type of the result is chosen.

These functions are generic: the supplied methods handle data frames and objects coercible to lists by [as.list](#).

### Value

`unstack` produces a list of columns according to the formula `form`. If all the columns have the same length, the resulting list is coerced to a data frame.

`stack` produces a data frame with two columns:

|                     |   |
|---------------------|---|
| <code>values</code> | the result of concatenating the selected vectors in <code>x</code> .                |
| <code>ind</code>    | a factor indicating from which vector in <code>x</code> the observation originated. |

### See Also

[lm](#), [reshape](#)

### Examples

```
require(stats)
formula(PlantGrowth)      # check the default formula
pg <- unstack(PlantGrowth) # unstack according to this formula
pg
stack(pg)                  # now put it back together
stack(pg, select = -ctrl)  # omitting one vector
```

---

str

*Compactly Display the Structure of an Arbitrary R Object*

---

### Description

Compactly display the internal **structure** of an R object, a diagnostic function and an alternative to [summary](#) (and to some extent, [dput](#)). Ideally, only one line for each ‘basic’ structure is displayed. It is especially well suited to compactly display the (abbreviated) contents of (possibly nested) lists. The idea is to give reasonable output for **any** R object. It calls [args](#) for (non-primitive) function objects.

`strOptions()` is a convenience function for setting [options](#) (`str = .`), see the examples.

### Usage

```
str(object, ...)
```

## S3 method for class 'data.frame'

```
str(object, ...)
```

## Default S3 method:

```
str(object, max.level = NA,
      vec.len  = strO$vec.len, digits.d = strO$digits.d,
      nchar.max = 128, give.attr = TRUE,
```

```

drop.deparse.attr = strO$drop.deparse.attr,
give.head = TRUE, give.length = give.head,
width = getOption("width"), nest.lev = 0,
indent.str = paste(rep.int(" ", max(0, nest.lev + 1)),
                    collapse = ".."),
comp.str = "$ ", no.list = FALSE, envir = baseenv(),
strict.width = strO$strict.width,
formatNum = strO$formatNum, list.len = strO$list.len,
deparse.lines = strO$deparse.lines, ...)

strOptions(strict.width = "no", digits.d = 3, vec.len = 4,
           list.len = 99, deparse.lines = NULL,
           drop.deparse.attr = TRUE,
           formatNum = function(x, ...)
             format(x, trim = TRUE, drop0trailing = TRUE, ...))

```

## Arguments

|                                |  |
|--------------------------------|--|
| <code>object</code>            | any R object about which you want to have some information.  |
| <code>max.level</code>         | maximal level of nesting which is applied for displaying nested structures, e.g., a list containing sub lists. Default NA: Display all nesting levels.   |
| <code>vec.len</code>           | numeric ( $\geq 0$ ) indicating how many ‘first few’ elements are displayed of each vector. The number is multiplied by different factors (from .5 to 3) depending on the kind of vector. Defaults to the <code>vec.len</code> component of option "str" (see <a href="#">options</a> ) which defaults to 4. |
| <code>digits.d</code>          | number of digits for numerical components (as for <a href="#">print</a> ). Defaults to the <code>digits.d</code> component of option "str" which defaults to 3.  |
| <code>nchar.max</code>         | maximal number of characters to show for <a href="#">character</a> strings. Longer strings are truncated, see longch example below.  |
| <code>give.attr</code>         | logical; if TRUE (default), show attributes as sub structures.   |
| <code>drop.deparse.attr</code> | logical; if TRUE (default), <a href="#">deparse</a> ( <code>control = control</code> ) will not have "showAttributes" in <i>control</i> . Used to be hard coded to FALSE and hence can be set via <code>strOptions()</code> for back compatibility.  |
| <code>give.length</code>       | logical; if TRUE (default), indicate length (as <code>[1:...] </code> ).   |
| <code>give.head</code>         | logical; if TRUE (default), give (possibly abbreviated) mode/class and length (as <code>type[1:...] </code> ).   |
| <code>width</code>             | the page width to be used. The default is the currently active <a href="#">options</a> ("width"); note that this has only a weak effect, unless <code>strict.width</code> is not "no".   |
| <code>nest.lev</code>          | current nesting level in the recursive calls to <code>str</code> .   |
| <code>indent.str</code>        | the indentation string to use.   |
| <code>comp.str</code>          | string to be used for separating list components.  |
| <code>no.list</code>           | logical; if true, no ‘list of ...’ nor the class are printed.  |
| <code>envir</code>             | the environment to be used for <i>promise</i> (see <a href="#">delayedAssign</a> ) objects only.   |
| <code>strict.width</code>      | string indicating if the <code>width</code> argument’s specification should be followed strictly, one of the values <code>c("no", "cut", "wrap")</code> , which can be abbreviated. Defaults to the <code>strict.width</code> component of option "str"  |

|                            |  |
|----------------------------|--|
|                            | (see <a href="#">options</a> ) which defaults to "no" for back compatibility reasons; "wrap" uses <a href="#">strwrap</a> (*, width = width) whereas "cut" cuts directly to width. Note that a small <code>vec.length</code> may be better than setting <code>strict.width = "wrap"</code> .                 |
| <code>formatNum</code>     | a function such as <a href="#">format</a> for formatting numeric vectors. It defaults to the <code>formatNum</code> component of option "str", see "Usage" of <code>strOptions()</code> above, which is almost back compatible to R <= 2.7.x, however, using <a href="#">formatC</a> may be slightly better. |
| <code>list.len</code>      | numeric; maximum number of list elements to display within a level.  |
| <code>deparse.lines</code> | numeric or NULL as by default, determining the <code>nlines</code> argument to <a href="#">deparse</a> () when object is a <a href="#">call</a> . When NULL, the <code>nchar.max</code> and <code>width</code> arguments are used to determine a smart default.  |
| <code>...</code>           | potential further arguments (required for Method/Generic reasons).   |

### Value

`str` does not return anything, for efficiency reasons. The obvious side effect is output to the terminal.

### Note

See the extensive annotated 'Examples' below.

The default method tries to "work always", but needs to make some assumptions for the case when object has a [class](#) but no own `str()` method which is *the typical* case: There it relies on "[" and "[[" subsetting methods to be compatible with [length](#)(). When this is not the case, or when `is.list(object)` is TRUE, but `length(object)` differs from `length(unclass(object))` it treats it as "irregular" and reports the contents of `unclass(object)` as "hidden list".

### Author(s)

Martin Maechler <maechler@stat.math.ethz.ch> since 1990.

---

strcapture*Capture String Tokens into a data.frame*

---

## Description

Given a character vector and a regular expression containing capture expressions, `strcapture` will extract the captured tokens into a tabular data structure, such as a `data.frame`, the type and structure of which is specified by a prototype object. The assumption is that the same number of tokens are captured from every input string.

## Usage

```
strcapture(pattern, x, proto, perl = FALSE, useBytes = FALSE)
```

## Arguments

|                             |  |
|-----------------------------|--|
| <code>pattern</code>        | The regular expression with the capture expressions.                       |
| <code>x</code>              | A character vector in which to capture the tokens.                         |
| <code>proto</code>          | A <code>data.frame</code> or S4 object that behaves like one. See details. |
| <code>perl, useBytes</code> | Arguments passed to <a href="#">regexec</a> .                              |

## Details

The `proto` argument is typically a `data.frame`, with a column corresponding to each capture expression, in order. The captured character vector is coerced to the type of the column, and the column names are carried over to the return value. Any data in the prototype are ignored. See the examples.

## Value

A tabular data structure of the same type as `proto`, so typically a `data.frame`, containing a column for each capture expression. The column types and names are inherited from `proto`. Cases in `x` that do not match `pattern` have NA in every column.

## See Also

[regexec](#) and [regmatches](#) for related low-level utilities.

## Examples

```
x <- "chr1:1-1000"
pattern <- "(.*) : ([[digit:]]+) - ([[digit:]]+)"
proto <- data.frame(chr=character(), start=integer(), end=integer())
strcapture(pattern, x, proto)
```

summaryRprof

*Summarise Output of R Sampling Profiler***Description**

Summarise the output of the [Rprof](#) function to show the amount of time used by different R functions.

**Usage**

```
summaryRprof(filename = "Rprof.out", chunksize = 5000,
             memory = c("none", "both", "tseries", "stats"),
             lines = c("hide", "show", "both"),
             index = 2, diff = TRUE, exclude = NULL,
             basenames = 1)
```

**Arguments**

|           |   |
|-----------|---|
| filename  | Name of a file produced by <code>Rprof()</code> .                                   |
| chunksize | Number of lines to read at a time.  |
| memory    | Summaries for memory information. See ‘Memory profiling’ below. Can be abbreviated. |
| lines     | Summaries for line information. See ‘Line profiling’ below. Can be abbreviated.     |
| index     | How to summarize the stack trace for memory information. See ‘Details’ below.       |
| diff      | If TRUE memory summaries use change in memory rather than current memory.           |
| exclude   | Functions to exclude when summarizing the stack trace for memory summaries.         |
| basenames | Number of components of the path to filenames to display.                           |

**Details**

This function provides the analysis code for [Rprof](#) files used by R CMD `Rprof`.

As the profiling output file could be larger than available memory, it is read in blocks of `chunksize` lines. Increasing `chunksize` will make the function run faster if sufficient memory is available.

**Value**

If `memory = "none"` and `lines = "hide"`, a list with components

|                              |   |
|------------------------------|---|
| <code>by.self</code>         | A data frame of timings sorted by ‘self’ time.  |
| <code>by.total</code>        | A data frame of timings sorted by ‘total’ time. |
| <code>sample.interval</code> | The sampling interval.                          |
| <code>sampling.time</code>   | Total time of profiling run.                    |

The first two components have columns ‘`self.time`’, ‘`self.pct`’, ‘`total.time`’ and ‘`total.pct`’, the times in seconds and percentages of the total time spent executing code in that function and code in that function or called from that function, respectively.

If `lines = "show"`, an additional component is added to the list:

`by.line` A data frame of timings sorted by source location.

If `memory = "both"` the same list but with memory consumption in Mb in addition to the timings.

If `memory = "tseries"` a data frame giving memory statistics over time. Memory usage is in bytes.

If `memory = "stats"` a `by` object giving memory statistics by function. Memory usage is in bytes.

If no events were recorded, a zero-row data frame is returned.

## Memory profiling

Options other than `memory = "none"` apply only to files produced by `Rprof` (`memory.profiling = TRUE`).

When called with `memory.profiling = TRUE`, the profiler writes information on three aspects of memory use: vector memory in small blocks on the R heap, vector memory in large blocks (from `malloc`), memory in nodes on the R heap. It also records the number of calls to the internal function `duplicate` in the time interval. `duplicate` is called by C code when arguments need to be copied. Note that the profiler does not track which function actually allocated the memory.

With `memory = "both"` the change in total memory (truncated at zero) is reported in addition to timing data.

With `memory = "tseries"` or `memory = "stats"` the `index` argument specifies how to summarize the stack trace. A positive number specifies that many calls from the bottom of the stack; a negative number specifies the number of calls from the top of the stack. With `memory = "tseries"` the `index` is used to construct labels and may be a vector to give multiple sets of labels. With `memory = "stats"` the `index` must be a single number and specifies how to aggregate the data to the maximum and average of the memory statistics. With both `memory = "tseries"` and `memory = "stats"` the argument `diff = TRUE` asks for summaries of the increase in memory use over the sampling interval and `diff = FALSE` asks for the memory use at the end of the interval.

## Line profiling

If the code being run has source reference information retained (via `keep.source = TRUE` in `source` or `KeepSource = TRUE` in a package ‘DESCRIPTION’ file or some other way), then information about the origin of lines is recorded during profiling. By default this is not displayed, but the `lines` parameter can enable the display.

If `lines = "show"`, line locations will be used in preference to the usual function name information, and the results will be displayed ordered by location in addition to the other orderings.

If `lines = "both"`, line locations will be mixed with function names in a combined display.

Rprof(tmp <- tempfile())
example(glm)
Rprof()
summaryRprof(tmp)
unlink(tmp)

## End(Not run)
```

---

Sweave

*Automatic Generation of Reports*

---

## Description

Sweave provides a flexible framework for mixing text and R/S code for automatic report generation. The basic idea is to replace the code with its output, such that the final document only contains the text and the output of the statistical analysis: however, the source code can also be included.

## Usage

```
Sweave(file, driver = RweaveLatex(),
       syntax = getOption("SweaveSyntax"), encoding = "", ...)

Stangle(file, driver = Rtangle(),
       syntax = getOption("SweaveSyntax"), encoding = "", ...)
```

## Arguments

|                       |  |
|-----------------------|--|
| <code>file</code>     | Path to Sweave source file. Note that this can be supplied without the extension, but the function will only proceed if there is exactly one Sweave file in the directory whose basename matches <code>file</code> . |
| <code>driver</code>   | the actual workhorse, (a function returning) a named <a href="#">list</a> of five functions; for details, see Section 5 of the ‘Sweave User Manual’ available as <code>vignette("Sweave")</code> .                   |
| <code>syntax</code>   | NULL or an object of class "SweaveSyntax" or a character string with its name. See the section ‘Syntax Definition’.  |
| <code>encoding</code> | The default encoding to assume for <code>file</code> .   |
| <code>...</code>      | further arguments passed to the driver’s setup function. See <a href="#">RweaveLatexSetup</a> and <a href="#">RtangleSetup</a> , respectively, for the arguments of the default drivers.                             |

## Details

An Sweave source file contains both text in a markup language (like  $\text{\LaTeX}$ ) and R (or S) code. The code gets replaced by its output (text or graphs) in the final markup file. This allows a report to be re-generated if the input data change and documents the code to reproduce the analysis in the same file that also produces the report.

Sweave combines the documentation and code chunks (or their output) into a single document. Stangle extracts only the code from the Sweave file creating an R source file that can be run using [source](#). (Code inside `\Sexpr{}` statements is ignored by Stangle.)

Stangle is just a wrapper to Sweave specifying a different default driver. Alternative drivers can be used and are provided by various contributed packages.

Environment variable `SWEAVE_OPTIONS` can be used to override the initial options set by the driver: it should be a comma-separated set of `key=value` items, as would be used in a `'\SweaveOpts'` statement in a document.

If the encoding is unspecified (the default), *non-ASCII* source files must contain a line of the form

```
\usepackage[foo]{inputenc}
```

(where ‘foo’ is typically ‘latin1’, ‘latin2’, ‘utf8’ or ‘cp1252’ or ‘cp1250’) or a comment line

```
%\SweaveUTF8
```

to declare UTF-8 input (the default encoding assumed by pdfTeX since 2018), or they will give an error. Re-encoding can be turned off completely with argument `encoding = "bytes"`.

### Syntax Definition

Sweave allows a flexible syntax framework for marking documentation and text chunks. The default is a noweb-style syntax, as alternative a L<sup>A</sup>T<sub>E</sub>X-style syntax can be used. (See the user manual for further details.)

If `syntax=NULL` (the default) then the available syntax objects are consulted in turn, and selected if their `extension` component matches (as a regexp) the file name. Objects `SweaveSyntaxNoweb` (with `extension = "[.] [rsRS]nw$"`) and `SweaveSyntaxLatex` (with `extension = "[.] [rsRS]tex$"`) are supplied, but users or packages can supply others with names matching the pattern `SweaveSyntax.*`.

**Examples**

```

testfile <- system.file("Sweave", "Sweave-test-1.Rnw", package = "utils")

## enforce par(ask = FALSE)
options(device.ask.default = FALSE)

## create a LaTeX file - in the current working directory, getwd():
Sweave(testfile)

## This can be compiled to PDF by
## tools::texi2pdf("Sweave-test-1.tex")

## or outside R by
##
## R CMD texi2pdf Sweave-test-1.tex
## on Unix-alikes which sets the appropriate TEXINPUTS path.
##
## On Windows,
## Rcmd texify --pdf Sweave-test-1.tex
## if MiKTeX is available.

## create an R source file from the code chunks
Stangle(testfile)
## which can be sourced, e.g.
source("Sweave-test-1.R")

```

SweaveSyntConv

*Convert Sweave Syntax***Description**

This function converts the syntax of files in [Sweave](#) format to another Sweave syntax definition.

**Usage**

```
SweaveSyntConv(file, syntax, output = NULL)
```

**Arguments**

|                     |  |
|---------------------|--|
| <code>file</code>   | Name of Sweave source file.  |
| <code>syntax</code> | An object of class <code>SweaveSyntax</code> or a character string with its name giving the target syntax to which the file is converted.  |
| <code>output</code> | Name of output file, default is to remove the extension from the input file and to add the default extension of the target syntax. Any directory names in <code>file</code> are also removed such that the output is created in the current working directory. |

testfile <- system.file("Sweave", "Sweave-test-1.Rnw", package = "utils")

## convert the file to latex syntax
SweaveSyntConv(testfile, SweaveSyntaxLatex)

## and run it through Sweave
Sweave("Sweave-test-1.Stex")
```

---

|     |                             |
|-----|-----------------------------|
| tar | <i>Create a Tar Archive</i> |
|-----|-----------------------------|

---

**Description**

Create a tar archive.

**Usage**

```
tar(tarfile, files = NULL,
    compression = c("none", "gzip", "bzip2", "xz"),
    compression_level = 6, tar = Sys.getenv("tar"),
    extra_flags = "")
```

**Arguments**

|                   |  |
|-------------------|--|
| tarfile           | The pathname of the tar file: tilde expansion (see <a href="#">path.expand</a> ) will be performed. Alternatively, a <a href="#">connection</a> that can be used for binary writes.  |
| files             | A character vector of filepaths to be archived: the default is to archive all files under the current directory.   |
| compression       | character string giving the type of compression to be used (default none). Can be abbreviated.   |
| compression_level | integer: the level of compression. Only used for the internal method.  |
| tar               | character string: the path to the command to be used. If the command itself contains spaces it needs to be quoted (e.g., by <a href="#">shQuote</a> ) – but argument <code>tar</code> may also contain flags separated from the command by spaces. |
| extra_flags       | Any extra flags for an external <code>tar</code> .   |

## Details

This is either a wrapper for a `tar` command or uses an internal implementation in R. The latter is used if `tarfile` is a connection or if the argument `tar` is `"internal"` or `" "` (the ‘factory-fresh’ default). Note that whereas Unix-alike versions of R set the environment variable `TAR`, its value is not the default for this function.

Argument `extra_flags` is passed to an external `tar` and so is platform-dependent. Possibly useful values include `‘-h’` (follow symbolic links, also `‘-L’` on some platforms), `‘--acls’`, `‘--exclude-backups’`, `‘--exclude-vcs’` (and similar) and on Windows `‘--force-local’` (so drives can be included in filepaths). Rtools 4 and earlier included a `tar` which used `‘--force-local’`, but Rtools  $\geq$  4.2 include the original GNU `tar`, which does not use it by default.

A convenient and robust way to set options for GNU `tar` is via environment variable `TAR_OPTIONS`. Appending `‘--force-local’` to `TAR` does not work with GNU `tar` due to restrictions on how some options can be mixed. The `tar` available on Windows 10 (libarchive’s `bsdtar`) supports drive letters by default. It does not support the `‘--force-local’`, but ignores `TAR_OPTIONS`.

For GNU `tar`, `‘--format=ustar’` forces a more portable format. (The default is set at compilation and will be shown at the end of the output from `tar --help`: for version 1.34 ‘out-of-the-box’ it is `‘--format=gnu’`, but the manual says the intention is to change @c <https://www.gnu.org/software/tar/manual/tar.html#Formats> to `‘--format=posix’` which is the same as `pax` – it was never part of the POSIX standard for `tar` and should not be used. However, the intention has been stated now for several years without changing the default.) For libarchive’s `bsdtar`, `‘--format=ustar’` is more portable than the default.

One issue which can cause an external command to fail is a command line too long for the system shell: as from R 3.5.0 this is worked around if the external command is detected to be GNU `tar` or libarchive `tar` (aka `bsdtar`).

Note that `files = ' . '` will usually not work with an external `tar` as that would expand the list of files after `tarfile` is created. (It does work with the default internal method.)

## Value

The return code from `system` or 0 for the internal version, invisibly.

## Portability

The ‘tar’ format no longer has an agreed standard! ‘Unix Standard Tar’ was part of POSIX 1003.1:1998 but has been removed in favour of `pax`, and in any case many common implementations diverged from the former standard.

Many R platforms use a version of GNU `tar`, but the behaviour seems to be changed with each version. macOS  $\geq$  10.6, FreeBSD and Windows 10 use `bsdtar` from the libarchive project (but for macOS often a quite-old version), and commercial Unixes will have their own versions. `bsdtar` is available for many other platforms: macOS up to at least 10.9 (but not recently) had GNU `tar` as `gnutar` and other platforms, e.g. Solaris, have it as `gtar`: on a Unix-alike configure will try `gnutar` and `gtar` before `tar`.

Known problems arise from

- The handling of file paths of more than 100 bytes. These were unsupported in early versions of `tar`, and supported in one way by POSIX `tar` and in another by GNU `tar` and yet another by the POSIX `pax` command which recent `tar` programs often support. The internal implementation warns on paths of more than 100 bytes, uses the ‘ustar’ way from the 1998

POSIX standard which supports up to 256 bytes (depending on the path: in particular the final component is limited to 100 bytes) if possible, otherwise the GNU way (which is widely supported, including by [untar](#)).

Most formats do not record the encoding of file paths.

- (File) links. `tar` was developed on an OS that used hard links, and physical files that were referred to more than once in the list of files to be included were included only once, the remaining instances being added as links. Later a means to include symbolic links was added. The internal implementation supports symbolic links (on OSes that support them), only. Of course, the question arises as to how links should be unpacked on OSes that do not support them: for regular files file copies can be used.

Names of links in the ‘ustar’ format are restricted to 100 bytes. There is an GNU extension for arbitrarily long link names, but `bsdtar` ignores it. The internal method uses the GNU extension, with a warning.

- Header fields, in particular the padding to be used when fields are not full or not used. POSIX did define the correct behaviour but commonly used implementations did (and still do) not comply.
- File sizes. The ‘ustar’ format is restricted to 8GB per (uncompressed) file.

For portability, avoid file paths of more than 100 bytes and all links (especially hard links and symbolic links to directories).

The internal implementation writes only the blocks of 512 bytes required (including trailing blocks of NULs), unlike GNU `tar` which by default pads with ‘`nul`’ to a multiple of 20 blocks (10KB). Implementations which pad differ on whether the block padding should occur before or after compression (or both): padding was designed for improved performance on physical tape drives.

The ‘ustar’ format records file modification times to a resolution of 1 second: on file systems with higher resolution it is conventional to discard fractional seconds.

## Compression

When an external `tar` command is used, compressing the tar archive requires that `tar` supports the ‘`-z`’, ‘`-j`’ or ‘`-J`’ flag, and may require the appropriate command (`gzip`, `bzip2` or `xz`) to be available. For GNU `tar`, further compression programs can be specified by e.g. `extra_flags = "-I lz4"`. Some versions of `bsdtar` accept options such as ‘`--lz4`’, ‘`--lzop`’ and ‘`--lrzip`’ or an external compressor *via* ‘`--use-compress-program lz4`’: these could be supplied in `extra_flags`.

NetBSD prior to 8.0 used flag ‘`--xz`’ rather than ‘`-J`’, so this should be used *via* `extra_flags = "--xz"` rather than `compression = "xz"`. The commands from OpenBSD and the Heirloom Toolchest are not documented to support `xz`.

The `tar` programs in commercial Unixen such as AIX and Solaris do not support compression.

## Note

For users of macOS. Apple’s file systems have a legacy concept of ‘resource forks’ dating from classic Mac OS and rarely used nowadays. Apple’s version of `tar` stores these as separate files in the tarball with names prefixed by ‘`._`’, and unpacks such files into resource forks (if possible): other ways of unpacking (including [untar](#) in R) unpack them as separate files.

When argument `tar` is set to the command `tar` on macOS, environment variable `COPYFILE_DISABLE=1` is set, which for the system version of `tar` prevents these separate files being included in the tarball.

[untar](#).

toLatex

*Converting R Objects to BibTeX or LaTeX***Description**

These methods convert R objects to character vectors with BibTeX or LaTeX markup.

**Usage**

```
toBibtex(object, ...)
toLatex(object, ...)
## S3 method for class 'Bibtex'
print(x, prefix = "", ...)
## S3 method for class 'Latex'
print(x, prefix = "", ...)
```

**Arguments**

|                     |  |
|---------------------|--|
| <code>object</code> | object of a class for which a <code>toBibtex</code> or <code>toLatex</code> method exists.                           |
| <code>x</code>      | object of class <code>"Bibtex"</code> or <code>"Latex"</code> .  |
| <code>prefix</code> | a character string which is printed at the beginning of each line, mostly used to insert whitespace for indentation. |
| <code>...</code>    | in the <code>print</code> methods, passed to <a href="#">writeLines</a> .  |

**Details**

Objects of class `"Bibtex"` or `"Latex"` are simply character vectors where each element holds one line of the corresponding BibTeX or LaTeX file.

---

|                |                          |
|----------------|--------------------------|
| txtProgressBar | <i>Text Progress Bar</i> |
|----------------|--------------------------|

---

## Description

Text progress bar in the R console.

## Usage

```
txtProgressBar(min = 0, max = 1, initial = 0, char = "=",
               width = NA, title, label, style = 1, file = "")

getTxtProgressBar(pb)
setTxtProgressBar(pb, value, title = NULL, label = NULL)
## S3 method for class 'txtProgressBar'
close(con, ...)
```

## Arguments

|               |   |
|---------------|---|
| min,max       | (finite) numeric values for the extremes of the progress bar. Must have <code>min &lt; max</code> .   |
| initial,value | initial or new value for the progress bar. See ‘Details’ for what happens with invalid values.  |
| char          | the character (or character string) to form the progress bar. Must have non-zero display width.   |
| width         | the width of the progress bar, as a multiple of the width of <code>char</code> . If <code>NA</code> , the default, the number of characters is that which fits into <code>getOption("width")</code> . |
| style         | the ‘style’ of the bar – see ‘Details’.   |
| file          | an open connection object or <code>" "</code> which indicates the console: <code>stderr()</code> might be useful here.  |
| pb,con        | an object of class <code>"txtProgressBar"</code> .  |
| title,label   | ignored, for compatibility with other progress bars.  |
| ...           | for consistency with the generic.   |

## Details

`txtProgressBar` will display a progress bar on the R console (or a connection) via a text representation.

`setTxtProgressBar` will update the value. Missing ([NA](#)) and out-of-range values of `value` will be (silently) ignored. (Such values of `initial` cause the progress bar not to be displayed until a valid value is set.)

The progress bar should be closed when finished with: this outputs the final newline character.

`style = 1` and `style = 2` just shows a line of `char`. They differ in that `style = 2` redraws the line each time, which is useful if other code might be writing to the R console. `style = 3` marks the end of the range by `'|'` and gives a percentage to the right of the bar.

**Value**

For `txtProgressBar` an object of class `"txtProgressBar"`.

For `getTxtProgressBar` and `setTxtProgressBar`, a length-one numeric vector giving the previous value (invisibly for `setTxtProgressBar`).

**Note**

Using `style 2` or `3` or reducing the value with `style = 1` uses `'\r'` to return to the left margin – the interpretation of carriage return is up to the terminal or console in which R is running, and this is liable to produce ugly output on a connection other than a terminal, including when `stdout()` is redirected to a file.

**See Also**

`winProgressBar` (Windows only), `tkProgressBar` (Unix-alike platforms).

**Examples**

```
# slow
testit <- function(x = sort(runif(20)), ...)
{
  pb <- txtProgressBar(...)
  for(i in c(0, x, 1)) {Sys.sleep(0.5); setTxtProgressBar(pb, i)}
  Sys.sleep(1)
  close(pb)
}
testit()
testit(runif(10))
testit(style = 3)
testit(char=' \u27a4')
```

---

type.convert

---

*Convert Data to Appropriate Type*

---

**Description**

Convert a data object to logical, integer, numeric, complex, character or factor as appropriate.

**Usage**

```
type.convert(x, ...)
## Default S3 method:
type.convert(x, na.strings = "NA", as.is, dec = ".",
             numerals = c("allow.loss", "warn.loss", "no.loss"),
             tryLogical = TRUE, ...)
## S3 method for class 'data.frame'
type.convert(x, ...)
## S3 method for class 'list'
type.convert(x, ...)
```

**Arguments**

|                         |  |
|-------------------------|--|
| <code>x</code>          | a vector, matrix, array, data frame, or list.  |
| <code>na.strings</code> | a vector of strings which are to be interpreted as <a href="#">NA</a> values. Blank fields are also considered to be missing values in logical, integer, numeric or complex vectors.   |
| <code>as.is</code>      | whether to store strings as plain character. When false, convert character vectors to factors. See ‘Details’.  |
| <code>dec</code>        | the character to be assumed for decimal points.  |
| <code>numerals</code>   | string indicating how to convert numbers whose conversion to double precision would lose accuracy, typically when <code>x</code> has more digits than can be stored in a <a href="#">double</a> . Can be abbreviated. Possible values are<br><code>numerals = "allow.loss"</code> , <b>default:</b> the conversion happens with some accuracy loss.<br><code>numerals = "warn.loss"</code> : a <a href="#">warning</a> about accuracy loss is signalled and the conversion happens as with <code>numerals = "allow.loss"</code> .<br><code>numerals = "no.loss"</code> : <code>x</code> is <i>not</i> converted to a number, but to a <a href="#">factor</a> or character, depending on <code>as.is</code> . |
| <code>tryLogical</code> | a <a href="#">logical</a> determining if vectors consisting entirely of F, T, FALSE, TRUE and <code>na.strings</code> should be converted to <a href="#">logical</a> ; true, by default.   |
| <code>...</code>        | arguments to be passed to or from methods.   |

**Details**

This helper function is used by [read.table](#). When the data object `x` is a data frame or list, the function is called recursively for each column or list element.

Given a vector, the function attempts to convert it to logical, integer, numeric or complex, and when additionally `as.is = FALSE` (no longer the default!), converts a character vector to [factor](#). The first type that can accept all the non-missing values is chosen.

Vectors which are entirely missing values are converted to logical, since `NA` is primarily logical.

If `tryLogical` is true as by default, vectors containing just F, T, FALSE, TRUE and values from `na.strings` are converted to logical. This may be surprising in a context where you have many character columns with e.g., 1-letter strings and you happen to get one with only "F". In such cases `tryLogical = FALSE` is recommended. Vectors containing optional whitespace followed by decimal constants representable as R integers or values from `na.strings` are converted to integer. Other vectors containing optional whitespace followed by other decimal or hexadecimal constants (see [NumericConstants](#)), or `NaN`, `Inf` or `infinity` (ignoring case) or values from `na.strings` are converted to numeric. Where converting inputs to numeric or complex would result in loss of accuracy they can optionally be returned as strings or (for `as.is = FALSE`) factors.

Since this is a helper function, the caller should always pass an appropriate value of `as.is`.

**Value**

An object like `x` but using another storage mode when appropriate.

**Author(s)**

R Core, with a contribution by Arni Magnusson

**See Also**

## Examples

```
## Numeric to integer
class(rivers)
x <- type.convert(rivers, as.is = TRUE)
class(x)

## Convert many columns
auto <- type.convert(mtcars, as.is = TRUE)
str(mtcars)
str(auto)

## Convert matrix
phones <- type.convert(WorldPhones, as.is = TRUE)
storage.mode(WorldPhones)
storage.mode(phones)

## Factor or character
chr <- c("A", "B", "B", "A")
ch2 <- c("F", "F", "NA", "F")
(fac <- factor(chr))
type.convert(chr, as.is = FALSE) # -> factor
type.convert(fac, as.is = FALSE) # -> factor
type.convert(chr, as.is = TRUE)  # -> character
type.convert(fac, as.is = TRUE)  # -> character
type.convert(ch2, as.is = TRUE)  # -> logical
type.convert(ch2, as.is = TRUE, tryLogical=FALSE) # -> character
```

---

untar

---

*Extract or List Tar Archives*

---

## Description

Extract files from or list the contents of a tar archive.

## Usage

```
untar(tarfile, files = NULL, list = FALSE, exdir = ".",
      compressed = NA, extras = NULL, verbose = FALSE,
      restore_times = TRUE,
      support_old_tars = Sys.getenv("R_SUPPORT_OLD_TARS", FALSE),
      tar = Sys.getenv("TAR"))
```

## Arguments

|         |  |
|---------|--|
| tarfile | The pathname of the tar file: tilde expansion (see <a href="#">path.expand</a> ) will be performed. Alternatively, a <a href="#">connection</a> that can be used for binary reads. For a <i>compressed</i> tarfile, and if a connection is to be used, that should be created by <a href="#">gzfile(.)</a> (or <a href="#">gzcon(.)</a> which currently only works for "gzip", whereas <a href="#">gzfile()</a> works for all compressions available in <a href="#">tar()</a> ). |
| files   | A character vector of recorded filepaths to be extracted: the default is to extract all files.   |
| list    | If TRUE, list the files (the equivalent of <code>tar -tf</code> ). Otherwise extract the files (the equivalent of <code>tar -xf</code> ).  |

|                               |  |
|-------------------------------|--|
| <code>exdir</code>            | The directory to extract files to (the equivalent of <code>tar -C</code> ). It will be created if necessary.   |
| <code>compressed</code>       | (Deprecated in favour of auto-detection, used only for an external <code>tar</code> command.) Logical or character string. Values <code>"gzip"</code> , <code>"bzip2"</code> and <code>"xz"</code> select that form of compression (and may be abbreviated to the first letter). <code>TRUE</code> indicates <code>gzip</code> compression, <code>FALSE</code> no known compression, and <code>NA</code> (the default) indicates that the type is to be inferred from the file header.<br>The external command may ignore the selected compression type but detect a type automatically. |
| <code>extras</code>           | <code>NULL</code> or a character string: further command-line flags such as <code>'-p'</code> to be passed to an external <code>tar</code> program.  |
| <code>verbose</code>          | logical: if <code>true</code> echo the command used for an external <code>tar</code> program.  |
| <code>restore_times</code>    | logical. If <code>true</code> (default) restore file modification times. If <code>false</code> , the equivalent of the <code>'-m'</code> flag. Times in tarballs are supposed to be in UTC, but tarballs have been submitted to CRAN with times in the future or far past: this argument allows such times to be discarded.<br>Note that file times in a tarball are stored with a resolution of 1 second, and can only be restored to the resolution supported by the file system (which on a FAT system is 2 seconds).   |
| <code>support_old_tars</code> | logical. If <code>false</code> (the default), the external <code>tar</code> command is assumed to be able handle compressed tarfiles and if <code>compressed</code> does not specify it, to automatically detect the type of compression. (The major implementations have done so since 2009; for GNU <code>tar</code> since version 1.22.)<br>If <code>true</code> , the R code calls an appropriate decompressor and pipes the output to <code>tar</code> , for <code>compressed = NA</code> examining the tarfile header to determine the type of compression.                        |
| <code>tar</code>              | character string: the path to the command to be used or <code>"internal"</code> . If the command itself contains spaces it needs to be quoted – but <code>tar</code> can also contain flags separated from the command by spaces.  |

## Details

This is either a wrapper for a `tar` command or for an internal implementation written in R. The latter is used if `tarfile` is a connection or if the argument `tar` is `"internal"` or `""` (except on Windows, when `tar.exe` is tried first).

Unless otherwise stated three types of compression of the tar file are supported: `gzip`, `bzip2` and `xz`.

What options are supported will depend on the `tar` implementation used: the `"internal"` one is intended to provide support for most in a platform-independent way.

**GNU `tar`:** Modern GNU `tar` versions support compressed archives and since 1.15 are able to detect the type of compression automatically: version 1.22 added support for `xz` compression.

On a Unix-alike, `configure` will set environment variable `TAR`, preferring GNU `tar` if found.

**bsdtar:** macOS 10.6 and later (and FreeBSD and some other OSes) have a `tar` from the libarchive project which detects all three forms of compression automatically (even if undocumented in macOS).

**NetBSD:** It is undocumented if NetBSD's `tar` can detect compression automatically: for versions before 8 the flag for `xz` compression was `--xz` not `-J`. So `support_old_tars = TRUE` is recommended (or use `bsdtar` if installed).

**OpenBSD:** OpenBSD's `tar` does not detect compression automatically. It has no support for `xz` beyond reporting that the file is `xz`-compressed. So `support_old_tars = TRUE` is recommended.

**Heirloom Toolchest:** This `tar` does automatically detect `gzip` and `bzip2` compression (undocumented) but has no support for `xz` compression.

**Older support:** Environment variable `R_GZIPCMD` gives the command to decompress `gzip` files, and `R_BZIPCMD` for `bzip2` files. (On Unix-alikes these are set at installation if found.) `xz` is used if available: if not decompression is expected to fail.

Arguments `compressed`, `extras` and `verbose` are only used when an external `tar` is used.

Some external `tar` commands will detect some of `lrzip`, `lzma`, `lz4`, `lzop` and `zstd` compression in addition to `gzip`, `bzip2` and `xz`. (For some external `tar` commands, compressed tarfiles can only be read if the appropriate utility program is available.) For GNU `tar`, further (de)compression programs can be specified by e.g. `extras = "-I lz4"`. For `bsdtar` this could be `extras = "--use-compress-program lz4"`. Most commands will detect (the nowadays rarely seen) `‘.tar.Z’` archives compressed by `compress`.

The internal implementation restores symbolic links as links on a Unix-alike, and as file copies on Windows (which works only for existing files, not for directories), and hard links as links. If the linking operation fails (as it may on a FAT file system), a file copy is tried. Since it uses `gzfile` to read a file it can handle files compressed by any of the methods that function can handle: at least `compress`, `gzip`, `bzip2` and `xz` compression, and some types of `lzma` compression. It does not guard against restoring absolute file paths, as some `tar` implementations do. It will create the parent directories for directories or files in the archive if necessary. It handles the USTAR/POSIX, GNU and `pax` ways of handling file paths of more than 100 bytes, and the GNU way of handling link targets of more than 100 bytes.

You may see warnings from the internal implementation such as

```
unsupported entry type 'x'
```

This often indicates an invalid archive: entry types "A-Z" are allowed as extensions, but other types are reserved. The only thing you can do with such an archive is to find a `tar` program that handles it, and look carefully at the resulting files. There may also be the warning

```
using pax extended headers
```

This indicates that additional information may have been discarded, such as ACLs, encodings ....

The former standards only supported ASCII filenames (indeed, only alphanumeric plus period, underscore and hyphen). `untar` makes no attempt to map filenames to those acceptable on the current system, and treats the filenames in the archive as applicable without any re-encoding in the current locale.

The internal implementation does not special-case 'resource forks' in macOS: that system's `tar` command does. This may lead to unexpected files with names with prefix `‘.__’`.

## Value

If `list = TRUE`, a character vector of (relative or absolute) paths of files contained in the `tar` archive.

Otherwise the return code from `system` with an external `tar` or 0L, invisibly.

**See Also**

[tar](#), [unzip](#).

---

unzip

---

*Extract or List Zip Archives*

---

**Description**

Extract files from or list a zip archive.

**Usage**

```
unzip(zipfile, files = NULL, list = FALSE, overwrite = TRUE,
      junkpaths = FALSE, exdir = ".", unzip = "internal",
      setTimes = FALSE)
```

**Arguments**

|           |   |
|-----------|---|
| zipfile   | The pathname of the zip file: tilde expansion (see <a href="#">path.expand</a> ) will be performed.   |
| files     | A character vector of recorded filepaths to be extracted: the default is to extract all files.  |
| list      | If TRUE, list the files and extract none. The equivalent of <code>unzip -l</code> .   |
| overwrite | If TRUE, overwrite existing files (the equivalent of <code>unzip -o</code> ), otherwise ignore such files (the equivalent of <code>unzip -n</code> ).             |
| junkpaths | If TRUE, use only the basename of the stored filepath when extracting. The equivalent of <code>unzip -j</code> .  |
| exdir     | The directory to extract files to (the equivalent of <code>unzip -d</code> ). It will be created if necessary.  |
| unzip     | The method to be used. An alternative is to use <code>getOption("unzip")</code> , which on a Unix-alike may be set to the path to a <code>unzip</code> program.   |
| setTimes  | logical. For the internal method only, should the file times be set based on the times in the zip file? (NB: this applies to included files, not to directories.) |

**Value**

If `list = TRUE`, a data frame with columns `Name` (character) `Length` (the size of the uncompressed file, numeric) and `Date` (of class `"POSIXct"`).

Otherwise for the `"internal"` method, a character vector of the filepaths extracted to, invisibly.

**Note**

The default internal method is a minimal implementation, principally designed for Windows' users to be able to unpack Windows binary packages without external software. It does not (for example) support Unicode filenames as introduced in `zip 3.0`: for that use `unzip = "unzip"` with `unzip 6.00` or later. It does have some support for `bzip2` compression and `> 2GB` zip files (but not `>= 4GB` files pre-compression contained in a zip file: like many builds of `unzip` it may truncate these, in R's case with a warning if possible).

If `unzip` specifies a program, the format of the dates listed with `list = TRUE` is unknown (on Windows it can even depend on the current locale) and the return values could be NA or expressed in the wrong time zone or misinterpreted (the latter being far less likely as from `unzip 6.00`).

File times in zip files are stored in the style of MS-DOS, as local times to an accuracy of 2 seconds. This is not very useful when transferring zip files between machines (even across continents), so we chose not to restore them by default.

### Source

The internal C code uses `zlib` and is in particular based on the contributed ‘minizip’ application in the `zlib` sources (from <https://zlib.net/>) by Gilles Vollant.

### See Also

`unz` to read a single component from a zip file.

`zip` for packing, i.e., the “inverse” of `unzip()`; further `untar` and `tar`, the corresponding pair for (un)packing tar archives (“tarballs”) such as R source packages.

---

update.packages

*Compare Installed Packages with CRAN-like Repositories*

---

### Description

`old.packages` indicates packages which have a (suitable) later version on the repositories whereas `update.packages` offers to download and install such packages.

`new.packages` looks for (suitable) packages on the repositories that are not already installed, and optionally offers them for installation.

### Usage

```
update.packages(lib.loc = NULL, repos = getOption("repos"),
               contriburl = contrib.url(repos, type),
               method, instlib = NULL,
               ask = TRUE, available = NULL,
               oldPkgs = NULL, ..., checkBuilt = FALSE,
               type = getOption("pkgType"))

old.packages(lib.loc = NULL, repos = getOption("repos"),
            contriburl = contrib.url(repos, type),
            instPkgs = installed.packages(lib.loc = lib.loc, ...),
            method, available = NULL, checkBuilt = FALSE, ...,
            type = getOption("pkgType"))

new.packages(lib.loc = NULL, repos = getOption("repos"),
            contriburl = contrib.url(repos, type),
            instPkgs = installed.packages(lib.loc = lib.loc, ...),
            method, available = NULL, ask = FALSE, ...,
            type = getOption("pkgType"))
```

**Arguments**

|                         |  |
|-------------------------|--|
| <code>lib.loc</code>    | character vector describing the location of R library trees to search through (and update packages therein), or <code>NULL</code> for all known trees (see <code>.libPaths</code> ).   |
| <code>repos</code>      | character vector, the base URL(s) of the repositories to use, e.g., the URL of a CRAN mirror such as <code>"https://cloud.r-project.org"</code> .  |
| <code>contriburl</code> | URL(s) of the contrib sections of the repositories. Use this argument if your repository is incomplete. Overrides argument <code>repos</code> . Incompatible with <code>type = "both"</code> .   |
| <code>method</code>     | Download method, see <code>download.file</code> . Unused if a non- <code>NULL</code> <code>available</code> is supplied.   |
| <code>instlib</code>    | character string giving the library directory where to install the packages.   |
| <code>ask</code>        | logical indicating whether to ask the user to select packages before they are downloaded and installed, or the character string <code>"graphics"</code> , which brings up a widget to allow the user to (de)select from the list of packages which could be updated. The latter value only works on systems with a GUI version of <code>select.list</code> , and is otherwise equivalent to <code>ask = TRUE</code> . <code>ask</code> does not control questions asked before installing packages from source via <code>type = "both"</code> (see option <code>"install.packages.compile.from.source"</code> ). |
| <code>available</code>  | an object as returned by <code>available.packages</code> listing packages available at the repositories, or <code>NULL</code> which makes an internal call to <code>available.packages</code> . Incompatible with <code>type = "both"</code> .   |
| <code>checkBuilt</code> | If <code>TRUE</code> , a package built under an earlier major.minor version of R (e.g., 3.4) is considered to be ‘old’.  |
| <code>oldPkgs</code>    | if specified as non- <code>NULL</code> , <code>update.packages()</code> only considers these packages for updating. This may be a character vector of package names or a matrix as returned by <code>old.packages</code> .   |
| <code>instPkgs</code>   | by default all installed packages, <code>installed.packages(lib.loc = lib.loc)</code> . A subset can be specified; currently this must be in the same (character matrix) format as returned by <code>installed.packages()</code> .   |
| <code>...</code>        | Arguments such as <code>destdir</code> and <code>dependencies</code> to be passed to <code>install.packages</code> and <code>ignore_repo_cache</code> , <code>max_repo_cache_age</code> and <code>noCache</code> to <code>available.packages</code> or <code>installed.packages</code> .   |
| <code>type</code>       | character, indicating the type of package to download and install. See <code>install.packages</code> .   |

**Details**

`old.packages` compares the information from `available.packages` with that from `instPkgs` (computed by `installed.packages` by default) and reports installed packages that have newer versions on the repositories or, if `checkBuilt = TRUE`, that were built under an earlier minor version of R (for example built under 3.3.x when running R 3.4.0). (For binary package types there is no check that the version on the repository was built under the current minor version of R, but it is advertised as being suitable for this version.)

`new.packages` does the same comparison but reports uninstalled packages that are available at the repositories. If `ask != FALSE` it asks which packages should be installed in the first element of `lib.loc`.

The main function of the set is `update.packages`. First a list of all packages found in `lib.loc` is created and compared with those available at the repositories. If `ask = TRUE` (the default) packages with a newer version are reported and for each one the user can specify if it should be updated. If so the packages are downloaded from the repositories and installed in the respective library path (or `instlib` if specified).

For how the list of suitable available packages is determined see `available.packages`. `available = NULL` make a call to `available.packages(contriburl = contriburl, method = method)` and hence by default filters on R version, OS type and removes duplicates.

### Value

`update.packages` returns `NULL` invisibly.

For `old.packages`, `NULL` or a matrix with one row per package, row names the package names and column names "Package", "LibPath", "Installed" (the version), "Built" (the version built under), "ReposVer" and "Repository".

For `new.packages` a character vector of package names, *after* any selected *via* `ask` have been installed.

### Warning

Take care when using dependencies (passed to `install.packages`) with `update.packages`, for it is unclear where new dependencies should be installed. The current implementation will only allow it if all the packages to be updated are in a single library, when that library will be used.

The ‘R Installation and Administration’ manual for how to set up a repository.

---

upgrade

*Upgrade*

---

### Description

Upgrade objects.

### Usage

```
upgrade(object, ...)
```

### Arguments

|                     |  |
|---------------------|--|
| <code>object</code> | an R object.                                       |
| <code>...</code>    | further arguments passed to or from other methods. |

## Details

This is a generic function, with a method for "[packageStatus](#)" objects.

---

|          |                           |
|----------|---------------------------|
| url.show | <i>Display a Text URL</i> |
|----------|---------------------------|

---

## Description

Extension of [file.show](#) to display text files from a remote server.

## Usage

```
url.show(url, title = url, file = tempfile(),
         delete.file = TRUE, method, ...)
```

## Arguments

|             |   |
|-------------|---|
| url         | The URL to read from.                                   |
| title       | Title for the browser.                                  |
| file        | File to copy to.  |
| delete.file | Delete the file afterwards?                             |
| method      | File transfer method: see <a href="#">download.file</a> |
| ...         | Arguments to pass to <a href="#">file.show</a> .        |

## Note

Since this is for text files, it will convert to CRLF line endings on Windows.

## See Also

## Examples

```
## Not run: url.show("https://www.stats.ox.ac.uk/pub/datasets/csb/ch3a.txt")
```

URLencode

*Encode or Decode (partial) URLs***Description**

Functions to percent-encode or decode characters in URLs.

**Usage**

```
URLencode(URL, reserved = FALSE, repeated = FALSE)
URLdecode(URL)
```

**Arguments**

|          |   |
|----------|---|
| URL      | a character vector.   |
| reserved | logical: should 'reserved' characters be encoded? See 'Details'.  |
| repeated | logical: should apparently already-encoded URLs be encoded again? |

**Details**

Characters in a URL other than the English alphanumeric characters and `'- _ . ~'` should be encoded as `%` plus a two-digit hexadecimal representation, and any single-byte character can be so encoded. (Multi-byte characters are encoded byte-by-byte.) The standard refers to this as 'percent-encoding'.

In addition, `'! $ & ' ( ) * + , ; = : / ? @ # [ ]'` are reserved characters, and should be encoded unless used in their reserved sense, which is scheme specific. The default in `URLencode` is to leave them alone, which is appropriate for `'file://'` URLs, but probably not for `'http://'` ones.

An 'apparently already-encoded URL' is one containing `%xx` for two hexadecimal digits.

**Value**

A character vector.

**References**

Internet STD 66 (formerly RFC 3986), <https://www.rfc-editor.org/info/std66>

**Examples**

```
(y <- URLencode("a url with spaces and / and @"))
URLdecode(y)
(y <- URLencode("a url with spaces and / and @", reserved = TRUE))
URLdecode(y)

URLdecode(z <- "ab%20cd")
c(URLencode(z), URLencode(z, repeated = TRUE)) # first is usually wanted

## both functions support character vectors of length > 1
y <- URLdecode(URLencode(c("url with space", "another one")))
```

---

utils-deprecated      *Deprecated Functions in Package **utils***

---

## Description

(Currently none)

These functions are provided for compatibility with older versions of R only, and may be defunct as soon as of the next release.

## See Also

[Deprecated](#), [Defunct](#)

---

View                      *Invoke a Data Viewer*

---

## Description

Invoke a spreadsheet-style data viewer on a matrix-like R object.

## Usage

```
View(x, title)
```

## Arguments

|                    |  |
|--------------------|--|
| <code>x</code>     | an R object which can be coerced to a data frame with non-zero numbers of rows and columns.  |
| <code>title</code> | title for viewer window. Defaults to name of <code>x</code> prefixed by <code>Data:</code> . |

## Details

Object `x` is coerced (if possible) to a data frame, then columns are converted to character using [format.data.frame](#). The object is then viewed in a spreadsheet-like data viewer, a read-only version of [data.entry](#).

If there are row names on the data frame that are not `1:nrow`, they are displayed in a separate first column called `row.names`.

Objects with zero columns or zero rows are not accepted.

**On Unix-alikes**, the array of cells can be navigated by the cursor keys and Home, End, Page Up and Page Down (where supported by X11) as well as Enter and Tab.

**On Windows**, the array of cells can be navigated *via* the scrollbars and by the cursor keys, Home, End, Page Up and Page Down.

On Windows, the initial size of the data viewer window is taken from the default dimensions of a pager (see [Rconsole](#)), but adjusted downwards to show a whole number of rows and columns.

**Value**

Invisible `NULL`. The function puts up a window and returns immediately: the window can be closed via its controls or menus.

**See Also**

`edit.data.frame`, `data.entry`.

---

|          |  |
|----------|--|
| vignette | <i>View, List or Get R Source of Package Vignettes</i> |
|----------|--|

---

**Description**

View a specified package vignette, or list the available ones; display it rendered in a viewer, and get or edit its R source file.

**Usage**

```
vignette(topic, package = NULL, lib.loc = NULL, all = TRUE)

## S3 method for class 'vignette'
print(x, ...)
## S3 method for class 'vignette'
edit(name, ...)
```

**Arguments**

|                      |   |
|----------------------|---|
| <code>topic</code>   | a character string giving the (base) name of the vignette to view. If omitted, all vignettes from all installed packages are listed.  |
| <code>package</code> | a character vector with the names of packages to search through, or <code>NULL</code> in which ‘all’ packages (as defined by argument <code>all</code> ) are searched.          |
| <code>lib.loc</code> | a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known.               |
| <code>all</code>     | logical; if <code>TRUE</code> search all available packages in the library trees specified by <code>lib.loc</code> , and if <code>FALSE</code> , search only attached packages. |
| <code>x, name</code> | object of class <code>vignette</code> .   |
| <code>...</code>     | ignored by the <code>print</code> method, passed on to <code>file.edit</code> by the <code>edit</code> method.  |

**Details**

Function `vignette` returns an object of the same class, the `print` method opens a viewer for it.

On Unix-alikes, the program specified by the `pdfviewer` option is used for viewing PDF versions of vignettes.

If several vignettes have PDF/HTML versions with base name identical to `topic`, the first one found is used.

If no topics are given, all available vignettes are listed. The corresponding information is returned in an object of class `"packageIQR"`.

**See Also**

[browseVignettes](#) for an HTML-based vignette browser; `RShowDoc("basename", package = "pkgname")` displays a “rendered” vignette (pdf or html).

**Examples**

```
## List vignettes from all *attached* packages
vignette(all = FALSE)

## List vignettes from all *installed* packages (can take a long time!):
vignette(all = TRUE)

## The grid intro vignette -- open it
## Not run: vignette("grid") # calling print()
## The same (conditional on existence of the vignette).
## Note that 'package = *' is much faster in the case of many installed packages:
if(!is.null(v1 <- vignette("grid", package="grid"))) {
  ## Not run: v1 # calling print(.)
  str(v1)
  ## Now let us have a closer look at the code

  ## Not run: edit(v1) # e.g., to send lines ...
} if( has vignette "installed")
## A package can have more than one vignette (package grid has several):
vignette(package = "grid")
if(interactive()) {
  ## vignette("rotated")
  ## The same, but without searching for it:
  vignette("rotated", package = "grid")
}
```

---

warnErrList

---

*Collect and Summarize Errors From List*

---

**Description**

Collect errors (class "error", typically from [tryCatch](#)) from a list `x` into a “summary warning”, by default produce a [warning](#) and keep that message as "warningMsg" attribute.

**Usage**

```
warnErrList(x, warn = TRUE, errValue = NULL)
```

**Arguments**

|                       |  |
|-----------------------|--|
| <code>x</code>        | a <a href="#">list</a> , typically from applying models to a list of data (sub)sets, e.g., using <a href="#">tryCatch</a> (*, error=identity). |
| <code>warn</code>     | logical indicating if <a href="#">warning</a> () should be called.   |
| <code>errValue</code> | the value with which errors should be replaced.  |

**Value**

a [list](#) of the same length and names as the `x` argument, with the error components replaced by `errValue`, [NULL](#) by default, and summarized in the `"warningMsg"` attribute.

**See Also**

The `warnErrList()` utility has been used in `lmList()` and `nlsList()` in recommended package **nlme** forever.

**Examples**

```
## Regression for each Chick:
ChWtgrps <- split(ChickWeight, ChickWeight[, "Chick"])
sapply(ChWtgrps, nrow) # typically 12 obs.
nlis1 <- lapply(ChWtgrps, function(DAT) tryCatch(error = identity,
  lm(weight ~ (Time + I(Time^2)) * Diet, data = DAT)))
nl1 <- warnErrList(nlis1) #-> warning :
## 50 times the same error (as Diet has only one level in each group)
stopifnot(sapply(nl1, is.null)) ## all errors --> all replaced by NULL
nlis2 <- lapply(ChWtgrps, function(DAT) tryCatch(error = identity,
  lm(weight ~ Time + I(Time^2), data = DAT)))
nl2 <- warnErrList(nlis2)
stopifnot(identical(nl2, nlis2)) # because there was *no* error at all
nlis3 <- lapply(ChWtgrps, function(DAT) tryCatch(error = identity,
  lm(weight ~ poly(Time, 3), data = DAT)))
nl3 <- warnErrList(nlis3) # 1 error caught:
stopifnot(inherits(nlis3[[1]], "error")
  , identical(nl3[-1], nlis3[-1])
  , is.null(nl3[[1]]))
)

## With different error messages
if(requireNamespace("nlme")) { # almost always, as it is recommended
  data(Soybean, package="nlme")
  attr(Soybean, "formula") #-> weight ~ Time | Plot => split by "Plot":
  L <- lapply(split(Soybean, Soybean[, "Plot"]),
    function(DD) tryCatch(error = identity,
      nls(weight ~ SSlogis(Time, Asym, xmid, scal), data = DD)))
  Lw <- warnErrList(L)
} # if <nlme>
```

---

winDialog

---

Dialog Boxes under Windows

---

**Description**

On MS Windows only, put up a dialog box to communicate with the user. There are various types, either for the user to select from a set of buttons or to edit a string.

**Usage**

```
winDialog(type = c("ok", "okcancel", "yesno", "yesnocancel"),
  message)

winDialogString(message, default)
```

**Arguments**

|                      |  |
|----------------------|--|
| <code>type</code>    | character. The type of dialog box. It will have the buttons implied by its name.                     |
| <code>message</code> | character. The information field of the dialog box. Limited to 255 chars (by Windows, checked by R). |
| <code>default</code> | character. The default string.   |

**Value**

For `winDialog` a character string giving the name of the button pressed (in capitals) or `NULL` (invisibly) if the user had no choice.

For `winDialogString` a string giving the contents of the text box when `Ok` was pressed, or `NULL` if `Cancel` was pressed.

**Note**

The standard keyboard accelerators work with these dialog boxes: where appropriate `Return` accepts the default action, `Esc` cancels and the underlined initial letter (`Y` or `N`) can be used.

These functions are only available on Windows.

**See Also**

[winMenuAdd](#)  
[file.choose](#) to select a file  
 package `windlgs` in the package source distribution for ways to program dialogs in C in the `GraphApp` toolkit.

**Examples**

```
## Not run: winDialog("yesno", "Is it OK to delete file blah")
```

---

winextras

*Get Windows Version*

---

**Description**

Get the self-reported Microsoft Windows version number.

**Usage**

```
win.version()
```

**Details**

`win.version` is an auxiliary function for [sessionInfo](#) and [bug.report](#).

**Value**

A character string describing the version of Windows reported to be in use.

**Note**

This function is only available on Microsoft Windows.

The result is based on the Windows `GetVersionEx` API function. It is not known how to detect a version of Windows before it is released, and hence the textual information returned by R may identify an older version than installed. The build number is more reliable. When running R in compatibility mode, the reported version including the build number is the compatibility version, not the installed version.

**Examples**

```
if(.Platform$OS.type == "windows")
  print(win.version())
```

---

winMenus

---

*User Menus under MS Windows (RGui)*

---

**Description**

Enables users to add, delete and program menus for the Rgui in MS Windows.

**Usage**

```
winMenuAdd(menuname)
winMenuAddItem(menuname, itemname, action)
winMenuDel(menuname)
winMenuDelItem(menuname, itemname)
winMenuNames()
winMenuItems(menuname)
```

**Arguments**

|          |  |
|----------|--|
| menuname | a character string naming a menu.  |
| itemname | a character string naming a menu item on an existing menu.                                     |
| action   | a character string describing the action when that menu is selected, or "enable" or "disable". |

**Details**

User menus are added to the right of existing menus, and items are added at the bottom of the menu. By default the action character string is treated as R input, being echoed on the command line and parsed and executed as usual.

If the `menuname` parameter of `winMenuAddItem` does not already exist, it will be created automatically.

Normally new submenus and menu items are added to the main console menu. They may be added elsewhere using the following special names:

```
$ConsoleMain The console menu (the default)
$ConsolePopup The console popup menu
$Graph<n>Main The menu for graphics window <n>
```

`$Graph<n>Popup` The popup menu for graphics window <n>

Specifying an existing item in `winMenuAddItem` enables the action to be changed.

Submenus can be specified by separating the elements in `menuname` by slashes: as a consequence menu names may not contain slashes.

If the `action` is specified as "none" no action is taken: this can be useful to reserve items for future expansion.

The function `winMenuNames` can be used to find out what menus have been created by the user and returns a vector of the existing menu names.

The `winMenuItems` function will take the name of a menu and return the items that exist in that menu. The return value is a named vector where the names correspond to the names of the items and the values of the vector are the corresponding actions.

The `winMenuDel` function will delete a menu and all of its items and submenus. `winMenuDelItem` just deletes one menu item.

The total path to an item (menu string plus item string) cannot exceed 1000 bytes, and the menu string cannot exceed 500 bytes.

## Value

NULL, invisibly. If an error occurs, an informative error message will be given.

## Note

These functions are only available on Windows and only when using the `Rgui`, hence not in `ESS` nor `RStudio`.

## See Also

[winDialog](#)

## Examples

```
## Not run:
winMenuAdd("Testit")
winMenuAddItem("Testit", "one", "aaaa")
winMenuAddItem("Testit", "two", "bbbb")
winMenuAdd("Testit/extras")
winMenuAddItem("Testit", "-", "")
winMenuAddItem("Testit", "two", "disable")
winMenuAddItem("Testit", "three", "cccc")
winMenuAddItem("Testit/extras", "one more", "ddd")
winMenuAddItem("Testit/extras", "and another", "eee")
winMenuAdd("$ConsolePopup/Testit")
winMenuAddItem("$ConsolePopup/Testit", "six", "fff")
winMenuNames()
winMenuItems("Testit")

## End(Not run)
```

---

|                |                                       |
|----------------|---------------------------------------|
| winProgressBar | <i>Progress Bars under MS Windows</i> |
|----------------|---------------------------------------|

---

## Description

Put up a Windows progress bar widget, update and access it.

## Usage

```
winProgressBar(title = "R progress bar", label = "",
               min = 0, max = 1, initial = 0, width = 300)

getWinProgressBar(pb)
setWinProgressBar(pb, value, title = NULL, label = NULL)
## S3 method for class 'winProgressBar'
close(con, ...)
```

## Arguments

|                |   |
|----------------|---|
| title, label   | character strings, giving the window title and the label on the dialog box respectively.      |
| min, max       | (finite) numeric values for the extremes of the progress bar.                                 |
| initial, value | initial or new value for the progress bar.  |
| width          | the width of the progress bar in pixels: the dialog box will be 40 pixels wider (plus frame). |
| pb, con        | an object of class "winProgressBar".  |
| ...            | for consistency with the generic.   |

## Details

winProgressBar will display a progress bar centred on the screen. Space will be allocated for the label only if it is non-empty.

setWinProgressbar will update the value and for non-NULL values, the title and label (provided there was one when the widget was created). Missing (NA) and out-of-range values of value will be (silently) ignored.

The progress bar should be closed when finished with, but it will be garbage-collected once no R object refers to it.

## Value

For winProgressBar an object of class "winProgressBar".

For getWinProgressBar and setWinProgressBar, a length-one numeric vector giving the previous value (invisibly for setWinProgressBar).

## Note

These functions are only available on Windows.

**See Also**

On all platforms, [txtProgressBar](#), [tkProgressBar](#)

---

|             |                    |
|-------------|--------------------|
| write.table | <i>Data Output</i> |
|-------------|--------------------|

---

**Description**

`write.table` prints its required argument `x` (after converting it to a data frame if it is not one nor a matrix) to a file or [connection](#).

**Usage**

```
write.table(x, file = "", append = FALSE, quote = TRUE, sep = " ",
            eol = "\n", na = "NA", dec = ".", row.names = TRUE,
            col.names = TRUE, qmethod = c("escape", "double"),
            fileEncoding = "")

write.csv(...)
write.csv2(...)
```

**Arguments**

|                        |   |
|------------------------|---|
| <code>x</code>         | the object to be written, preferably a matrix or data frame. If not, it is attempted to coerce <code>x</code> to a data frame.  |
| <code>file</code>      | either a character string naming a file or a <a href="#">connection</a> open for writing. "" indicates output to the console.   |
| <code>append</code>    | logical. Only relevant if <code>file</code> is a character string. If TRUE, the output is appended to the file. If FALSE, any existing file of the name is destroyed.   |
| <code>quote</code>     | a logical value (TRUE or FALSE) or a numeric vector. If TRUE, any character or factor columns will be surrounded by double quotes. If a numeric vector, its elements are taken as the indices of columns to quote. In both cases, row and column names are quoted if they are written. If FALSE, nothing is quoted. |
| <code>sep</code>       | the field separator string. Values within each row of <code>x</code> are separated by this string.  |
| <code>eol</code>       | the character(s) to print at the end of each line (row). For example, <code>eol = "\r\n"</code> will produce Windows' line endings on a Unix-alike OS, and <code>eol = "\r"</code> will produce files as expected by Excel:mac 2004.  |
| <code>na</code>        | the string to use for missing values in the data.   |
| <code>dec</code>       | the string to use for decimal points in numeric or complex columns: must be a single character.   |
| <code>row.names</code> | either a logical value indicating whether the row names of <code>x</code> are to be written along with <code>x</code> , or a character vector of row names to be written.   |
| <code>col.names</code> | either a logical value indicating whether the column names of <code>x</code> are to be written along with <code>x</code> , or a character vector of column names to be written. See the section on 'CSV files' for the meaning of <code>col.names = NA</code> .   |

`qmethod` a character string specifying how to deal with embedded double quote characters when quoting strings. Must be one of "escape" (default for `write.table`), in which case the quote character is escaped in C style by a backslash, or "double" (default for `write.csv` and `write.csv2`), in which case it is doubled. You can specify just the initial letter.

`fileEncoding` character string: if non-empty declares the encoding to be used on a file (not a connection) so the character data can be re-encoded as they are written. See [file](#).

... arguments to `write.table`: `append`, `col.names`, `sep`, `dec` and `qmethod` cannot be altered.

## Details

If the table has no columns the rownames will be written only if `row.names = TRUE`, and *vice versa*.

Real and complex numbers are written to the maximal possible precision.

If a data frame has matrix-like columns these will be converted to multiple columns in the result (*via* `as.matrix`) and so a character `col.names` or a numeric `quote` should refer to the columns in the result, not the input. Such matrix-like columns are unquoted by default.

Any columns in a data frame which are lists or have a class (e.g., dates) will be converted by the appropriate `as.character` method: such columns are unquoted by default. On the other hand, any class information for a matrix is discarded and non-atomic (e.g., list) matrices are coerced to character.

Only columns which have been converted to character will be quoted if specified by `quote`.

The `dec` argument only applies to columns that are not subject to conversion to character because they have a class or are part of a matrix-like column (or matrix), in particular to columns protected by `I()`. Use `options("OutDec")` to control such conversions.

In almost all cases the conversion of numeric quantities is governed by the option "scipen" (see [options](#)), but with the internal equivalent of `digits = 15`. For finer control, use `format` to make a character matrix/data frame, and call `write.table` on that.

These functions check for a user interrupt every 1000 lines of output.

If `file` is a non-open connection, an attempt is made to open it and then close it after use.

To write a Unix-style file on Windows, use a binary connection e.g. `file = file("filename", "wb")`.

## CSV files

By default there is no column name for a column of row names. If `col.names = NA` and `row.names = TRUE` a blank column name is added, which is the convention used for CSV files to be read by spreadsheets. Note that such CSV files can be read in R by

```
read.csv(file = "<filename>", row.names = 1)
```

`write.csv` and `write.csv2` provide convenience wrappers for writing CSV files. They set `sep` and `dec` (see below), `qmethod = "double"`, and `col.names` to NA if `row.names = TRUE` (the default) and to TRUE otherwise.

`write.csv` uses "." for the decimal point and a comma for the separator.

`write.csv2` uses a comma for the decimal point and a semicolon for the separator, the Excel convention for CSV files in some Western European locales.

These wrappers are deliberately inflexible: they are designed to ensure that the correct conventions are used to write a valid file. Attempts to change `append`, `col.names`, `sep`, `dec` or `qmethod` are ignored, with a warning.

CSV files do not record an encoding, and this causes problems if they are not ASCII for many other applications. Windows Excel 2007/10 will open files (e.g., by the file association mechanism) correctly if they are ASCII or UTF-16 (use `fileEncoding = "UTF-16LE"`) or perhaps in the current Windows codepage (e.g., "CP1252"), but the 'Text Import Wizard' (from the 'Data' tab) allows far more choice of encodings. Excel:mac 2004/8 can *import* only 'Macintosh' (which seems to mean Mac Roman), 'Windows' (perhaps Latin-1) and 'PC-8' files. OpenOffice 3.x asks for the character set when opening the file.

There is an IETF RFC4180 (<https://www.rfc-editor.org/rfc/rfc4180>) for CSV files, which mandates comma as the separator and CRLF line endings. `write.csv` writes compliant files on Windows: use `eol = "\r\n"` on other platforms.

### Note

`write.table` can be slow for data frames with large numbers (hundreds or more) of columns: this is inevitable as each column could be of a different class and so must be handled separately. If they are all of the same class, consider using a matrix instead.

### See Also

The 'R Data Import/Export' manual.

`read.table`, `write`.

`write.matrix` in package **MASS**.

### Examples

```
x <- data.frame(a = I("a \" quote"), b = pi)
tf <- tempfile(fileext = ".csv")

## To write a CSV file for input to Excel one might use
write.table(x, file = tf, sep = ",", col.names = NA,
            qmethod = "double")
file.show(tf)
## and to read this file back into R one needs
read.table(tf, header = TRUE, sep = ",", row.names = 1)
## NB: you do need to specify a separator if qmethod = "double".

### Alternatively
write.csv(x, file = tf)
read.csv(tf, row.names = 1)
## or without row names
write.csv(x, file = tf, row.names = FALSE)
read.csv(tf)

## Not run:
## To write a file in Mac Roman for simple use in Mac Excel 2004/8
write.csv(x, file = "foo.csv", fileEncoding = "macroman")
## or for Windows Excel 2007/10
write.csv(x, file = "foo.csv", fileEncoding = "UTF-16LE")

## End(Not run)
```

---

zip

---

*Create Zip Archives*

---

**Description**

A wrapper for an external `zip` command to create zip archives.

**Usage**

```
zip(zipfile, files, flags = "-r9X", extras = "",  
    zip = Sys.getenv("R_ZIPCMD", "zip"))
```

**Arguments**

|                      |   |
|----------------------|---|
| <code>zipfile</code> | The pathname of the zip file: tilde expansion (see <a href="#">path.expand</a> ) will be performed. |
| <code>files</code>   | A character vector of recorded filepaths to be included.  |
| <code>flags</code>   | A character string of flags to be passed to the command: see ‘Details’.                             |
| <code>extras</code>  | An optional character vector: see ‘Details’.  |
| <code>zip</code>     | A character string specifying the external command to be used.                                      |

**Details**

On a Unix-alike, the default for `zip` will use the value of `R_ZIPCMD`, whose default is set in ‘etc/Renviron’ to the `zip` command found during configuration. On Windows, the default relies on a `zip` program (for example that from Rtools) being in the path.

The default for `flags` is that appropriate for zipping up a directory tree in a portable way: see the system-specific help for the `zip` command for other possibilities.

Argument `extras` can be used to specify `-x` or `-i` followed by a list of filepaths to exclude or include. Since `extras` will be treated as if passed to [system](#), if the filepaths contain spaces they must be quoted e.g. by [shQuote](#).

**Value**

The status value returned by the external command, invisibly.

**See Also**

[unzip](#), [unz](#); further, [tar](#) and [untar](#) for (un)packing tar archives.

## **Part II**

## Chapter 15

# The KernSmooth package

---

bkde

*Compute a Binned Kernel Density Estimate*

---

### Description

Returns x and y coordinates of the binned kernel density estimate of the probability density of the data.

### Usage

```
bkde(x, kernel = "normal", canonical = FALSE, bandwidth,  
      gridsize = 401L, range.x, truncate = TRUE)
```

### Arguments

|           |  |
|-----------|--|
| x         | numeric vector of observations from the distribution whose density is to be estimated. Missing values are not allowed.   |
| bandwidth | the kernel bandwidth smoothing parameter. Larger values of <code>bandwidth</code> make smoother estimates, smaller values of <code>bandwidth</code> make less smooth estimates. The default is a bandwidth computed from the variance of <code>x</code> , specifically the ‘oversmoothed bandwidth selector’ of Wand and Jones (1995, page 61).                |
| kernel    | character string which determines the smoothing kernel. <code>kernel</code> can be: "normal" - the Gaussian density function (the default). "box" - a rectangular box. "epanech" - the centred beta(2,2) density. "biweight" - the centred beta(3,3) density. "triweight" - the centred beta(4,4) density. This can be abbreviated to any unique abbreviation. |
| canonical | length-one logical vector: if TRUE, canonically scaled kernels are used.   |
| gridsize  | the number of equally spaced points at which to estimate the density.  |
| range.x   | vector containing the minimum and maximum values of <code>x</code> at which to compute the estimate. The default is the minimum and maximum data values, extended by the support of the kernel.  |
| truncate  | logical flag: if TRUE, data with <code>x</code> values outside the range specified by <code>range.x</code> are ignored.  |

## Details

This is the binned approximation to the ordinary kernel density estimate. Linear binning is used to obtain the bin counts. For each  $x$  value in the sample, the kernel is centered on that  $x$  and the heights of the kernel at each datapoint are summed. This sum, after a normalization, is the corresponding  $y$  value in the output.

## Value

a list containing the following components:

|     |   |
|-----|---|
| $x$ | vector of sorted $x$ values at which the estimate was computed. |
| $y$ | vector of density estimates at the corresponding $x$ .          |

## Background

Density estimation is a smoothing operation. Inevitably there is a trade-off between bias in the estimate and the estimate's variability: large bandwidths will produce smooth estimates that may hide local features of the density; small bandwidths may introduce spurious bumps into the estimate.

## References

Wand, M. P. and Jones, M. C. (1995). *Kernel Smoothing*. Chapman and Hall, London.

## See Also

[density](#), [dpik](#), [hist](#), [ksmooth](#).

## Examples

```
data(geyser, package="MASS")
x <- geyser$duration
est <- bkde(x, bandwidth=0.25)
plot(est, type="l")
```

---

bkde2D

---

*Compute a 2D Binned Kernel Density Estimate*

---

## Description

Returns the set of grid points in each coordinate direction, and the matrix of density estimates over the mesh induced by the grid points. The kernel is the standard bivariate normal density.

## Usage

```
bkde2D(x, bandwidth, gridsize = c(51L, 51L), range.x, truncate = TRUE)
```

## Arguments

|                        |  |
|------------------------|--|
| <code>x</code>         | a two-column numeric matrix containing the observations from the distribution whose density is to be estimated. Missing values are not allowed.  |
| <code>bandwidth</code> | numeric vector of length 2, containing the bandwidth to be used in each coordinate direction.  |
| <code>gridsize</code>  | vector containing the number of equally spaced points in each direction over which the density is to be estimated.   |
| <code>range.x</code>   | a list containing two vectors, where each vector contains the minimum and maximum values of <code>x</code> at which to compute the estimate for each direction. The default minimum in each direction is minimum data value minus 1.5 times the bandwidth for that direction. The default maximum is the maximum data value plus 1.5 times the bandwidth for that direction. |
| <code>truncate</code>  | logical flag: if TRUE, data with <code>x</code> values outside the range specified by <code>range.x</code> are ignored.  |

## Value

a list containing the following components:

|                   |  |
|-------------------|--|
| <code>x1</code>   | vector of values of the grid points in the first coordinate direction at which the estimate was computed.  |
| <code>x2</code>   | vector of values of the grid points in the second coordinate direction at which the estimate was computed. |
| <code>fhat</code> | matrix of density estimates over the mesh induced by <code>x1</code> and <code>x2</code> .                 |

## Details

This is the binned approximation to the 2D kernel density estimate. Linear binning is used to obtain the bin counts and the Fast Fourier Transform is used to perform the discrete convolutions. For each `x1,x2` pair the bivariate Gaussian kernel is centered on that location and the heights of the kernel, scaled by the bandwidths, at each datapoint are summed. This sum, after a normalization, is the corresponding `fhat` value in the output.

## Examples

```
data(geyser, package="MASS")
x <- cbind(geyser$duration, geyser$waiting)
est <- bkde2D(x, bandwidth=c(0.7, 7))
contour(est$x1, est$x2, est$fhat)
persp(est$fhat)
```

bkfe

*Compute a Binned Kernel Functional Estimate***Description**

Returns an estimate of a binned approximation to the kernel estimate of the specified density functional. The kernel is the standard normal density.

**Usage**

```
bkfe(x, drv, bandwidth, gridsize = 401L, range.x, binned = FALSE,
      truncate = TRUE)
```

**Arguments**

|                        |   |
|------------------------|---|
| <code>x</code>         | numeric vector of observations from the distribution whose density is to be estimated. Missing values are not allowed.  |
| <code>drv</code>       | order of derivative in the density functional. Must be a non-negative even integer.   |
| <code>bandwidth</code> | the kernel bandwidth smoothing parameter. Must be supplied.   |
| <code>gridsize</code>  | the number of equally-spaced points over which binning is performed.  |
| <code>range.x</code>   | vector containing the minimum and maximum values of <code>x</code> at which to compute the estimate. The default is the minimum and maximum data values, extended by the support of the kernel. |
| <code>binned</code>    | logical flag: if <code>TRUE</code> , then <code>x</code> and <code>y</code> are taken to be grid counts rather than raw data.   |
| <code>truncate</code>  | logical flag: if <code>TRUE</code> , data with <code>x</code> values outside the range specified by <code>range.x</code> are ignored.   |

**Details**

The density functional of order `drv` is the integral of the product of the density and its `drv`th derivative. The kernel estimates of such quantities are computed using a binned implementation, and the kernel is the standard normal density.

**Value**

the (scalar) estimated functional.

**Background**

Estimates of this type were proposed by Sheather and Jones (1991).

**References**

Sheather, S. J. and Jones, M. C. (1991). A reliable data-based bandwidth selection method for kernel density estimation. *Journal of the Royal Statistical Society, Series B*, **53**, 683–690.

**Examples**

```
data(geyser, package="MASS")
x <- geyser$duration
est <- bkfe(x, drv=4, bandwidth=0.3)
```

---

|             |                                     |
|-------------|-------------------------------------|
| <i>dpih</i> | <i>Select a Histogram Bin Width</i> |
|-------------|-------------------------------------|

---

**Description**

Uses direct plug-in methodology to select the bin width of a histogram.

**Usage**

```
dpih(x, scalest = "minim", level = 2L, gridsize = 401L,
      range.x = range(x), truncate = TRUE)
```

**Arguments**

|                       |  |
|-----------------------|--|
| <code>x</code>        | numeric vector containing the sample on which the histogram is to be constructed.  |
| <code>scalest</code>  | estimate of scale.<br>"stdev" - standard deviation is used.<br>"iqr" - inter-quartile range divided by 1.349 is used.<br>"minim" - minimum of "stdev" and "iqr" is used.                           |
| <code>level</code>    | number of levels of functional estimation used in the plug-in rule.  |
| <code>gridsize</code> | number of grid points used in the binned approximations to functional estimates.   |
| <code>range.x</code>  | range over which functional estimates are obtained. The default is the minimum and maximum data values.  |
| <code>truncate</code> | if <code>truncate</code> is <code>TRUE</code> then observations outside of the interval specified by <code>range.x</code> are omitted. Otherwise, they are used to weight the extreme grid points. |

**Details**

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bin width and bandwidths are replaced by kernel estimates, is used. The normal distribution is used to provide an initial estimate.

**Value**

the selected bin width.

**Background**

This method for selecting the bin width of a histogram is described in Wand (1995). It is an extension of the normal scale rule of Scott (1979) and uses plug-in ideas from bandwidth selection for kernel density estimation (e.g. Sheather and Jones, 1991).

---

|      |  |
|------|--|
| dpik | Select a Bandwidth for Kernel Density Estimation |
|------|--|

---

Description

Use direct plug-in methodology to select the bandwidth of a kernel density estimate.

Usage

```
dpik(x, scalest = "minim", level = 2L, kernel = "normal",
     canonical = FALSE, gridsize = 401L, range.x = range(x),
     truncate = TRUE)
```

Arguments

|           |   |
|-----------|---|
| x         | numeric vector containing the sample on which the kernel density estimate is to be constructed.   |
| scalest   | estimate of scale.<br>"stdev" - standard deviation is used.<br>"iqr" - inter-quartile range divided by 1.349 is used.<br>"minim" - minimum of "stdev" and "iqr" is used.  |
| level     | number of levels of functional estimation used in the plug-in rule.   |
| kernel    | character string which determines the smoothing kernel. kernel can be: "normal" - the Gaussian density function (the default). "box" - a rectangular box. "epanech" - the centred beta(2,2) density. "biweight" - the centred beta(3,3) density. "triweight" - the centred beta(4,4) density. This can be abbreviated to any unique abbreviation. |
| canonical | logical flag: if TRUE, canonically scaled kernels are used  |
| gridsize  | the number of equally-spaced points over which binning is performed to obtain kernel functional approximation.  |

|                       |  |
|-----------------------|--|
| <code>range.x</code>  | vector containing the minimum and maximum values of <code>x</code> at which to compute the estimate. The default is the minimum and maximum data values. |
| <code>truncate</code> | logical flag: if <code>TRUE</code> , data with <code>x</code> values outside the range specified by <code>range.x</code> are ignored.                    |

### Details

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bandwidths are replaced by kernel estimates, is used. The normal distribution is used to provide an initial estimate.

### Value

the selected bandwidth.

### Background

This method for selecting the bandwidth of a kernel density estimate was proposed by Sheather and Jones (1991) and is described in Section 3.6 of Wand and Jones (1995).

### References

- Sheather, S. J. and Jones, M. C. (1991). A reliable data-based bandwidth selection method for kernel density estimation. *Journal of the Royal Statistical Society, Series B*, **53**, 683–690.

dpill

---

*Select a Bandwidth for Local Linear Regression*

---

### Description

Use direct plug-in methodology to select the bandwidth of a local linear Gaussian kernel regression estimate, as described by Ruppert, Sheather and Wand (1995).

### Usage

```
dpill(x, y, blockmax = 5, divisor = 20, trim = 0.01, proptrun = 0.05,
      gridsize = 401L, range.x, truncate = TRUE)
```

### Arguments

|                       |  |
|-----------------------|--|
| <code>x</code>        | numeric vector of <code>x</code> data. Missing values are not accepted.  |
| <code>y</code>        | numeric vector of <code>y</code> data. This must be same length as <code>x</code> , and missing values are not accepted.   |
| <code>blockmax</code> | the maximum number of blocks of the data for construction of an initial parametric estimate.   |
| <code>divisor</code>  | the value that the sample size is divided by to determine a lower limit on the number of blocks of the data for construction of an initial parametric estimate.  |
| <code>trim</code>     | the proportion of the sample trimmed from each end in the <code>x</code> direction before application of the plug-in methodology.  |
| <code>proptrun</code> | the proportion of the range of <code>x</code> at each end truncated in the functional estimates.   |
| <code>gridsize</code> | number of equally-spaced grid points over which the function is to be estimated.   |
| <code>range.x</code>  | vector containing the minimum and maximum values of <code>x</code> at which to compute the estimate. For density estimation the default is the minimum and maximum data values with 5% of the range added to each end. For regression estimation the default is the minimum and maximum data values. |
| <code>truncate</code> | logical flag: if TRUE, data with <code>x</code> values outside the range specified by <code>range.x</code> are ignored.  |

### Details

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bandwidths are replaced by kernel estimates, is used. The kernel is the standard normal density. Least squares quartic fits over blocks of data are used to obtain an initial estimate. Mallows's  $C_p$  is used to select the number of blocks.

### Value

the selected bandwidth.

### Warning

If there are severe irregularities (i.e. outliers, sparse regions) in the `x` values then the local polynomial smooths required for the bandwidth selection algorithm may become degenerate and the function will crash. Outliers in the `y` direction may lead to deterioration of the quality of the selected bandwidth.

**Examples**

```
data(geyser, package = "MASS")
x <- geyser$duration
y <- geyser$waiting
plot(x, y)
h <- dpill(x, y)
fit <- locpoly(x, y, bandwidth = h)
lines(fit)
```

locpoly

*Estimate Functions Using Local Polynomials***Description**

Estimates a probability density function, regression function or their derivatives using local polynomials. A fast binned implementation over an equally-spaced grid is used.

**Usage**

```
locpoly(x, y, drv = 0L, degree, kernel = "normal",
        bandwidth, gridsize = 401L, bwdisc = 25,
        range.x, binned = FALSE, truncate = TRUE)
```

**Arguments**

|                        |   |
|------------------------|---|
| <code>x</code>         | numeric vector of <code>x</code> data. Missing values are not accepted.   |
| <code>bandwidth</code> | the kernel bandwidth smoothing parameter. It may be a single number or an array having length <code>gridsize</code> , representing a bandwidth that varies according to the location of estimation. |
| <code>y</code>         | vector of <code>y</code> data. This must be same length as <code>x</code> , and missing values are not accepted.  |
| <code>drv</code>       | order of derivative to be estimated.  |
| <code>degree</code>    | degree of local polynomial used. Its value must be greater than or equal to the value of <code>drv</code> . The default value is of degree is <code>drv + 1</code> .                                |
| <code>kernel</code>    | "normal" - the Gaussian density function. Currently ignored.  |
| <code>gridsize</code>  | number of equally-spaced grid points over which the function is to be estimated.  |
| <code>bwdisc</code>    | number of logarithmically-equally-spaced bandwidths on which <code>bandwidth</code> is discretised, to speed up computation.  |
| <code>range.x</code>   | vector containing the minimum and maximum values of <code>x</code> at which to compute the estimate.  |
| <code>binned</code>    | logical flag: if <code>TRUE</code> , then <code>x</code> and <code>y</code> are taken to be grid counts rather than raw data.   |
| <code>truncate</code>  | logical flag: if <code>TRUE</code> , data with <code>x</code> values outside the range specified by <code>range.x</code> are ignored.   |

**Value**

if `y` is specified, a local polynomial regression estimate of  $E[Y|X]$  (or its derivative) is computed. If `y` is missing, a local polynomial estimate of the density of `x` (or its derivative) is computed.

a list containing the following components:

|                |   |
|----------------|---|
| <code>x</code> | vector of sorted <code>x</code> values at which the estimate was computed.                                  |
| <code>y</code> | vector of smoothed estimates for either the density or the regression at the corresponding <code>x</code> . |

**Details**

Local polynomial fitting with a kernel weight is used to estimate either a density, regression function or their derivatives. In the case of density estimation, the data are binned and the local fitting procedure is applied to the bin counts. In either case, binned approximations over an equally-spaced grid is used for fast computation. The bandwidth may be either scalar or a vector of length `gridsize`.

addterm

---

Try All One-Term Additions to a Model

---

**Description**

Try fitting all models that differ from the current model by adding a single term from those supplied, maintaining marginality.

This function is generic; there exist methods for classes `lm` and `glm` and the default method will work for many other classes.

**Usage**

```
addterm(object, ...)

## Default S3 method:
addterm(object, scope, scale = 0, test = c("none", "Chisq"),
        k = 2, sorted = FALSE, trace = FALSE, ...)
## S3 method for class 'lm'
addterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),
        k = 2, sorted = FALSE, ...)
## S3 method for class 'glm'
addterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),
        k = 2, sorted = FALSE, trace = FALSE, ...)
```

**Arguments**

|                     |   |
|---------------------|---|
| <code>object</code> | An object fitted by some model-fitting function.  |
| <code>scope</code>  | a formula specifying a maximal model which should include the current one. All additional terms in the maximal model with all marginal terms in the original model are tried.   |
| <code>scale</code>  | used in the definition of the AIC statistic for selecting the models, currently only for <code>lm</code> , <code>aov</code> and <code>glm</code> models. Specifying <code>scale</code> asserts that the residual standard error or dispersion is known.   |
| <code>test</code>   | should the results include a test statistic relative to the original model? The F test is only appropriate for <code>lm</code> and <code>aov</code> models, and perhaps for some over-dispersed <code>glm</code> models. The Chisq test can be an exact test ( <code>lm</code> models with known scale) or a likelihood-ratio test depending on the method. |
| <code>k</code>      | the multiple of the number of degrees of freedom used for the penalty. Only <code>k=2</code> gives the genuine AIC: $k = \log(n)$ is sometimes referred to as BIC or SBC.   |
| <code>sorted</code> | should the results be sorted on the value of AIC?   |
| <code>trace</code>  | if TRUE additional information may be given on the fits as they are tried.  |
| <code>...</code>    | arguments passed to or from other methods.  |

## Details

The definition of AIC is only up to an additive constant: when appropriate (l<sub>m</sub> models with specified scale) the constant is taken to be that used in Mallows' Cp statistic and the results are labelled accordingly.

## Value

A table of class "anova" containing at least columns for the change in degrees of freedom and AIC (or Cp) for the models. Some methods will give further information, for example sums of squares, deviances, log-likelihoods and test statistics.

## References

Aids2

---

*Australian AIDS Survival Data*

---

## Description

Data on patients diagnosed with AIDS in Australia before 1 July 1991.

## Usage

Aids2

## Format

This data frame contains 2843 rows and the following columns:

state Grouped state of origin: "NSW" includes ACT and "other" is WA, SA, NT and TAS.  
sex Sex of patient.  
diag (Julian) date of diagnosis.  
death (Julian) date of death or end of observation.  
status "A" (alive) or "D" (dead) at end of observation.  
T.categ Reported transmission category.  
age Age (years) at diagnosis.

**Note**

This data set has been slightly jittered as a condition of its release, to ensure patient confidentiality.

---

anova.negbin

*Likelihood Ratio Tests for Negative Binomial GLMs*

---

### Description

Method function to perform sequential likelihood ratio tests for Negative Binomial generalized linear models.

### Usage

```
## S3 method for class 'negbin'
anova(object, ..., test = "Chisq")
```

### Arguments

|                     |   |
|---------------------|---|
| <code>object</code> | Fitted model object of class <code>"negbin"</code> , inheriting from classes <code>"glm"</code> and <code>"lm"</code> , specifying a Negative Binomial fitted GLM. Typically the output of <code>glm.nb()</code> .                                    |
| <code>...</code>    | Zero or more additional fitted model objects of class <code>"negbin"</code> . They should form a nested sequence of models, but need not be specified in any particular order.  |
| <code>test</code>   | Argument to match the <code>test</code> argument of <code>anova.glm</code> . Ignored (with a warning if changed) if a sequence of two or more Negative Binomial fitted model objects is specified, but possibly used if only one object is specified. |

### Details

This function is a method for the generic function `anova()` for class `"negbin"`. It can be invoked by calling `anova(x)` for an object `x` of the appropriate class, or directly by calling `anova.negbin(x)` regardless of the class of the object.

### Note

If only one fitted model object is specified, a sequential analysis of deviance table is given for the fitted model. The `theta` parameter is kept fixed. If more than one fitted model object is specified they must all be of class `"negbin"` and likelihood ratio tests are done of each model within the next. In this case `theta` is assumed to have been re-estimated for each model.

### References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

### See Also

`glm.nb`, `negative.binomial`, `summary.negbin`

### Examples

```
m1 <- glm.nb(Days ~ Eth*Age*Lrn*Sex, quine, link = log)
m2 <- update(m1, . ~ . - Eth:Age:Lrn:Sex)
anova(m2, m1)
anova(m2)
```

---

area

*Adaptive Numerical Integration*

---

### Description

Integrate a function of one variable over a finite range using a recursive adaptive method. This function is mainly for demonstration purposes.

### Usage

```
area(f, a, b, ..., fa = f(a, ...), fb = f(b, ...),
     limit = 10, eps = 1e-05)
```

**Arguments**

|                    |  |
|--------------------|--|
| <code>f</code>     | The integrand as an S function object. The variable of integration must be the first argument. |
| <code>a</code>     | Lower limit of integration.  |
| <code>b</code>     | Upper limit of integration.  |
| <code>...</code>   | Additional arguments needed by the integrand.  |
| <code>fa</code>    | Function value at the lower limit.   |
| <code>fb</code>    | Function value at the upper limit.   |
| <code>limit</code> | Limit on the depth to which recursion is allowed to go.  |
| <code>eps</code>   | Error tolerance to control the process.  |

**Details**

The method divides the interval in two and compares the values given by Simpson's rule and the trapezium rule. If these are within `eps` of each other the Simpson's rule result is given, otherwise the process is applied separately to each half of the interval and the results added together.

**Value**

The integral from `a` to `b` of  $f(x)$ .

**References**

Venables, W. N. and Ripley, B. D. (1994) *Modern Applied Statistics with S-Plus*. Springer. pp. 105–110.

**Examples**

```
area(sin, 0, pi) # integrate the sin function from 0 to pi.
```

---

bacteria

*Presence of Bacteria after Drug Treatments*

---

**Description**

Tests of the presence of the bacteria *H. influenzae* in children with otitis media in the Northern Territory of Australia.

**Usage**

```
bacteria
```

**Format**

This data frame has 220 rows and the following columns:

**y** presence or absence: a factor with levels `n` and `y`.

**ap** active/placebo: a factor with levels `a` and `p`.

**hilo** hi/low compliance: a factor with levels `hi` and `lo`.

**week** numeric: week of test.

**ID** subject ID: a factor.

**trt** a factor with levels `placebo`, `drug` and `drug+`, a re-coding of `ap` and `hilo`.

## Details

Dr A. Leach tested the effects of a drug on 50 children with a history of otitis media in the Northern Territory of Australia. The children were randomized to the drug or the a placebo, and also to receive active encouragement to comply with taking the drug.

The presence of *H. influenzae* was checked at weeks 0, 2, 4, 6 and 11: 30 of the checks were missing and are not included in this data frame.

---

bandwidth.nrd

*Bandwidth for density() via Normal Reference Distribution*

---

## Description

A well-supported rule-of-thumb for choosing the bandwidth of a Gaussian kernel density estimator.

**Usage**

```
bandwidth.nrd(x)
```

**Arguments**

`x`                      A data vector.

**Value**

A bandwidth on a scale suitable for the `width` argument of `density`.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Springer, equation (5.5) on page 130.

**Examples**

```
# The function is currently defined as
function(x)
{
  r <- quantile(x, c(0.25, 0.75))
  h <- (r[2] - r[1])/1.34
  4 * 1.06 * min(sqrt(var(x)), h) * length(x)^(-1/5)
}
```

---

bcv

*Biased Cross-Validation for Bandwidth Selection*

---

**Description**

Uses biased cross-validation to select the bandwidth of a Gaussian kernel density estimator.

**Usage**

```
bcv(x, nb = 1000, lower, upper)
```

**Arguments**

`x`                      a numeric vector  
`nb`                     number of bins to use.  
`lower, upper`        Range over which to minimize. The default is almost always satisfactory.

**Value**

a bandwidth

beav1

*Body Temperature Series of Beaver 1*

---

**Description**

Reynolds (1994) describes a small part of a study of the long-term temperature dynamics of beaver *Castor canadensis* in north-central Wisconsin. Body temperature was measured by telemetry every 10 minutes for four females, but data from a one period of less than a day for each of two animals is used there.

**Usage**

```
beav1
```

**Format**

The `beav1` data frame has 114 rows and 4 columns. This data frame contains the following columns:

`day` Day of observation (in days since the beginning of 1990), December 12–13.

`time` Time of observation, in the form 0330 for 3.30am.

`temp` Measured body temperature in degrees Celsius.

`activ` Indicator of activity outside the retreat.

**Note**

The observation at 22:20 is missing.

**Source**

P. S. Reynolds (1994) Time-series analyses of beaver body temperatures. Chapter 11 of Lange, N., Ryan, L., Billard, L., Brillinger, D., Conquest, L. and Greenhouse, J. eds (1994) *Case Studies in Biometry*. New York: John Wiley and Sons.

biopsy*Biopsy Data on Breast Cancer Patients*

---

**Description**

This breast cancer database was obtained from the University of Wisconsin Hospitals, Madison from Dr. William H. Wolberg. He assessed biopsies of breast tumours for 699 patients up to 15 July 1992; each of nine attributes has been scored on a scale of 1 to 10, and the outcome is also known. There are 699 rows and 11 columns.

**Usage**

biopsy

**Format**

This data frame contains the following columns:

ID sample code number (not unique).  
V1 clump thickness.  
V2 uniformity of cell size.  
V3 uniformity of cell shape.  
V4 marginal adhesion.  
V5 single epithelial cell size.  
V6 bare nuclei (16 values are missing).  
V7 bland chromatin.  
V8 normal nucleoli.  
V9 mitoses.  
class "benign" or "malignant".

birthwt

*Risk Factors Associated with Low Infant Birth Weight*

---

## Description

The `birthwt` data frame has 189 rows and 10 columns. The data were collected at Baystate Medical Center, Springfield, Mass during 1986.

## Usage

```
birthwt
```

## Format

This data frame contains the following columns:

`low` indicator of birth weight less than 2.5 kg.  
`age` mother's age in years.  
`lwt` mother's weight in pounds at last menstrual period.  
`race` mother's race (1 = white, 2 = black, 3 = other).  
`smoke` smoking status during pregnancy.  
`ptl` number of previous premature labours.  
`ht` history of hypertension.  
`ui` presence of uterine irritability.  
`ftv` number of physician visits during the first trimester.  
`bwt` birth weight in grams.

  ptd <- factor(ptl > 0)
  ftv <- factor(ftv)
  levels(ftv)[-1:2] <- "2+"
  data.frame(low = factor(low), age, lwt, race, smoke = (smoke > 0),
             ptd, ht = (ht > 0), ui = (ui > 0), ftv)
})
options(contrasts = c("contr.treatment", "contr.poly"))
glm(low ~ ., binomial, bwt)
```

---

Boston*Housing Values in Suburbs of Boston*

---

**Description**

The `Boston` data frame has 506 rows and 14 columns.

**Usage**

`Boston`

**Format**

This data frame contains the following columns:

`crim` per capita crime rate by town.

`zn` proportion of residential land zoned for lots over 25,000 sq.ft.

`indus` proportion of non-retail business acres per town.

`chas` Charles River dummy variable (= 1 if tract bounds river; 0 otherwise).

`nox` nitrogen oxides concentration (parts per 10 million).

`rm` average number of rooms per dwelling.

`age` proportion of owner-occupied units built prior to 1940.

`dis` weighted mean of distances to five Boston employment centres.

`rad` index of accessibility to radial highways.

`tax` full-value property-tax rate per \$10,000.

`ptratio` pupil-teacher ratio by town.

`black`  $1000(Bk - 0.63)^2$  where  $Bk$  is the proportion of blacks by town.

`lstat` lower status of the population (percent).

`medv` median value of owner-occupied homes in \$1000s.

**Source**

boxcox

*Box-Cox Transformations for Linear Models***Description**

Computes and optionally plots profile log-likelihoods for the parameter of the Box-Cox power transformation.

**Usage**

```
boxcox(object, ...)
```

```
## Default S3 method:
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE,
        interp, eps = 1/50, xlab = expression(lambda),
        ylab = "log-Likelihood", ...)
```

```
## S3 method for class 'formula'
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE,
        interp, eps = 1/50, xlab = expression(lambda),
        ylab = "log-Likelihood", ...)
```

```
## S3 method for class 'lm'
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE,
        interp, eps = 1/50, xlab = expression(lambda),
        ylab = "log-Likelihood", ...)
```

**Arguments**

|                     |   |
|---------------------|---|
| <code>object</code> | a formula or fitted model object. Currently only <code>lm</code> and <code>aov</code> objects are handled.  |
| <code>lambda</code> | vector of values of <code>lambda</code> – default $(-2, 2)$ in steps of 0.1.  |
| <code>plotit</code> | logical which controls whether the result should be plotted.  |
| <code>interp</code> | logical which controls whether spline interpolation is used. Default to <code>TRUE</code> if plotting with <code>lambda</code> of length less than 100. |
| <code>eps</code>    | Tolerance for <code>lambda = 0</code> ; defaults to 0.02.   |
| <code>xlab</code>   | defaults to <code>"lambda"</code> .   |
| <code>ylab</code>   | defaults to <code>"log-Likelihood"</code> .   |
| <code>...</code>    | additional parameters to be used in the model fitting.  |

**Value**

A list of the `lambda` vector and the computed profile log-likelihood vector, invisibly if the result is plotted.

**Side Effects**

If `plotit = TRUE` plots log-likelihood vs `lambda` and indicates a 95% confidence interval about the maximum observed value of `lambda`. If `interp = TRUE`, spline interpolation is used to give a smoother plot.

## Examples

```
boxcox(Volume ~ log(Height) + log(Girth), data = trees,
       lambda = seq(-0.25, 0.25, length.out = 10))

boxcox(Days+1 ~ Eth*Sex*Age*Lrn, data = quine,
       lambda = seq(-0.05, 0.45, length.out = 20))
```

---

cabbages

*Data from a cabbage field trial*

---

## Description

The cabbages data set has 60 observations and 4 variables

## Usage

```
cabbages
```

## Format

This data frame contains the following columns:

**Cult** Factor giving the cultivar of the cabbage, two levels: c39 and c52.

**Date** Factor specifying one of three planting dates: d16, d20 or d21.

**HeadWt** Weight of the cabbage head, presumably in kg.

**VitC** Ascorbic acid content, in undefined units.

Cars93

*Data from 93 Cars on Sale in the USA in 1993*

---

### Description

The Cars93 data frame has 93 rows and 27 columns.

### Usage

```
Cars93
```

### Format

This data frame contains the following columns:

Manufacturer Manufacturer.

Model Model.

Type Type: a factor with levels "Small", "Sporty", "Compact", "Midsize", "Large" and "Van".

Min.Price Minimum Price (in \$1,000): price for a basic version.

Price Midrange Price (in \$1,000): average of Min.Price and Max.Price.

Max.Price Maximum Price (in \$1,000): price for "a premium version".

MPG.city City MPG (miles per US gallon by EPA rating).

MPG.highway Highway MPG.

AirBags Air Bags standard. Factor: none, driver only, or driver & passenger.

DriveTrain Drive train type: rear wheel, front wheel or 4WD; (factor).

Cylinders Number of cylinders (missing for Mazda RX-7, which has a rotary engine).

EngineSize Engine size (litres).

Horsepower Horsepower (maximum).

RPM RPM (revs per minute at maximum horsepower).

Rev.per.mile Engine revolutions per mile (in highest gear).

Man.trans.avail Is a manual transmission version available? (yes or no, Factor).

Fuel.tank.capacity Fuel tank capacity (US gallons).

Passengers Passenger capacity (persons)

Length Length (inches).

Wheelbase Wheelbase (inches).

Width Width (inches).

Turn.circle U-turn space (feet).

Rear.seat.room Rear seat room (inches) (missing for 2-seater vehicles).

Luggage.room Luggage capacity (cubic feet) (missing for vans).

Weight Weight (pounds).

Origin Of non-USA or USA company origins? (factor).

Make Combination of Manufacturer and Model (character).

### Details

Cars were selected at random from among 1993 passenger car models that were listed in both the *Consumer Reports* issue and the *PACE Buying Guide*. Pickup trucks and Sport/Utility vehicles were eliminated due to incomplete information in the *Consumer Reports* source. Duplicate models (e.g., Dodge Shadow and Plymouth Sundance) were listed at most once.

Further description can be found in Lock (1993).

cement

*Heat Evolved by Setting Cements*

---

## Description

Experiment on the heat evolved in the setting of each of 13 cements.

## Usage

cement

## Format

x1, x2, x3, x4 Proportions (%) of active ingredients.

y heat evolved in cal/gm.

**Details**

Thirteen samples of Portland cement were set. For each sample, the percentages of the four main chemical ingredients was accurately measured. While the cement was setting the amount of heat evolved was also measured.

**Source**

Woods, H., Steinour, H.H. and Starke, H.R. (1932) Effect of composition of Portland cement on heat evolved during hardening. *Industrial Engineering and Chemistry*, **24**, 1207–1214.

---

`con2tr`
*Convert Lists to Data Frames for use by lattice*

---

### Description

Convert lists to data frames for use by lattice.

### Usage

```
con2tr(obj)
```

### Arguments

`obj` A list of components `x`, `y` and `z` as passed to `contour`.

### Details

`con2tr` repeats the `x` and `y` components suitably to match the vector `z`.

### Value

A data frame suitable for passing to lattice (formerly trellis) functions.

### References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

---

`confint-MASS`
*Confidence Intervals for Model Parameters*

---

### Description

Computes confidence intervals for one or more parameters in a fitted model. Package **MASS** added methods for `glm` and `nls` fits. As from R 4.4.0 these have been migrated to package **stats**.

It also adds a method for `polr` fits.

---

 contr.sdif

*Successive Differences Contrast Coding*

---

## Description

A coding for factors based on successive differences.

## Usage

```
contr.sdif(n, contrasts = TRUE, sparse = FALSE)
```

## Arguments

|                        |  |
|------------------------|--|
| <code>n</code>         | The number of levels required.   |
| <code>contrasts</code> | logical: Should there be $n - 1$ columns orthogonal to the mean (the default) or $n$ columns spanning the space?         |
| <code>sparse</code>    | logical. If true and the result would be sparse (only true for <code>contrasts = FALSE</code> ), return a sparse matrix. |

## Details

The contrast coefficients are chosen so that the coded coefficients in a one-way layout are the differences between the means of the second and first levels, the third and second levels, and so on. This makes most sense for ordered factors, but does not assume that the levels are equally spaced.

## Value

If `contrasts` is `TRUE`, a matrix with  $n$  rows and  $n - 1$  columns, and the  $n$  by  $n$  identity matrix if `contrasts` is `FALSE`.

## References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth Edition, Springer.

## S3 method for class 'data.frame'
corresp(x, ...)

## S3 method for class 'xtabs'
corresp(x, ...)

## S3 method for class 'formula'
corresp(formula, data, ...)
```

**Arguments**

|            |  |
|------------|--|
| x, formula | The function is generic, accepting various forms of the principal argument for specifying a two-way frequency table. Currently accepted forms are matrices, data frames (coerced to frequency tables), objects of class " <a href="#">xtabs</a> " and formulae of the form $\sim F1 + F2$ , where $F1$ and $F2$ are factors. |
| nf         | The number of factors to be computed. Note that although 1 is the most usual, one school of thought takes the first two singular vectors for a sort of biplot.   |
| y          | a second factor for a cross-classification.  |
| data       | an optional data frame, list or environment against which to preferentially resolve variables in the formula.  |
| ...        | If the principal argument is a formula, a data frame may be specified as well from which variables in the formula are preferentially satisfied.  |

**Details**

See Venables & Ripley (2002). The `plot` method produces a graphical representation of the table if `nf=1`, with the *areas* of circles representing the numbers of points. If `nf` is two or more the `biplot` method is called, which plots the second and third columns of the matrices  $A = D_r^{(-1/2)} U L$  and  $B = D_c^{(-1/2)} V L$  where the singular value decomposition is  $U L V$ . Thus the x-axis is the canonical correlation times the row and column scores. Although this is called a biplot, it does *not* have any useful inner product relationship between the row and column scores. Think of this as an equally-scaled plot with two unrelated sets of labels. The origin is marked on the plot with a cross. (For other versions of this plot see the book.)

**Value**

An list object of class "correspondence" for which `print`, `plot` and `biplot` methods are supplied. The main components are the canonical correlation(s) and the row and column scores.

cov.rob

*Resistant Estimation of Multivariate Location and Scatter*

---

**Description**

Compute a multivariate location and scale estimate with a high breakdown point – this can be thought of as estimating the mean and covariance of the good part of the data. `cov.mve` and `cov.mcd` are compatibility wrappers.

**Usage**

```
cov.rob(x, cor = FALSE, quantile.used = floor((n + p + 1)/2),
        method = c("mve", "mcd", "classical"),
        nsamp = "best", seed)

cov.mve(...)
cov.mcd(...)
```

**Arguments**

|                            |  |
|----------------------------|--|
| <code>x</code>             | a matrix or data frame.  |
| <code>cor</code>           | should the returned result include a correlation matrix?   |
| <code>quantile.used</code> | the minimum number of the data points regarded as good points.   |
| <code>method</code>        | the method to be used – minimum volume ellipsoid, minimum covariance determinant or classical product-moment. Using <code>cov.mve</code> or <code>cov.mcd</code> forces <code>mve</code> or <code>mcd</code> respectively.   |
| <code>nsamp</code>         | the number of samples or "best" or "exact" or "sample". The limit If "sample" the number chosen is $\min(5 \cdot p, 3000)$ , taken from Rousseeuw and Hubert (1997). If "best" exhaustive enumeration is done up to 5000 samples: if "exact" exhaustive enumeration will be attempted. |
| <code>seed</code>          | the seed to be used for random sampling: see <a href="#">RNGkind</a> . The current value of <code>.Random.seed</code> will be preserved if it is set.  |
| <code>...</code>           | arguments to <code>cov.rob</code> other than <code>method</code> .   |

## Details

For method "mve", an approximate search is made of a subset of size `quantile.used` with an enclosing ellipsoid of smallest volume; in method "mcd" it is the volume of the Gaussian confidence ellipsoid, equivalently the determinant of the classical covariance matrix, that is minimized. The mean of the subset provides a first estimate of the location, and the rescaled covariance matrix a first estimate of scatter. The Mahalanobis distances of all the points from the location estimate for this covariance matrix are calculated, and those points within the 97.5% point under Gaussian assumptions are declared to be `good`. The final estimates are the mean and rescaled covariance of the `good` points.

The rescaling is by the appropriate percentile under Gaussian data; in addition the first covariance matrix has an *ad hoc* finite-sample correction given by Marazzi.

For method "mve" the search is made over ellipsoids determined by the covariance matrix of `p` of the data points. For method "mcd" an additional improvement step suggested by Rousseeuw and van Driessen (1999) is used, in which once a subset of size `quantile.used` is selected, an ellipsoid based on its covariance is tested (as this will have no larger a determinant, and may be smaller).

There is a hard limit on the allowed number of samples,  $2^{31} - 1$ . However, practical limits are likely to be much lower and one might check the number of samples used for exhaustive enumeration, `combn(NROW(x), NCOL(x) + 1)`, before attempting it.

## Value

A list with components

|                     |   |
|---------------------|---|
| <code>center</code> | the final estimate of location.   |
| <code>cov</code>    | the final estimate of scatter.  |
| <code>cor</code>    | (only is <code>cor = TRUE</code> ) the estimate of the correlation matrix.  |
| <code>sing</code>   | message giving number of singular samples out of total  |
| <code>crit</code>   | the value of the criterion on log scale. For MCD this is the determinant, and for MVE it is proportional to the volume. |
| <code>best</code>   | the subset used. For MVE the best sample, for MCD the best set of size <code>quantile.used</code> .                     |
| <code>n.obs</code>  | total number of observations.   |

cov.trob

*Covariance Estimation for Multivariate t Distribution***Description**

Estimates a covariance or correlation matrix assuming the data came from a multivariate t distribution: this provides some degree of robustness to outlier without giving a high breakdown point.

**Usage**

```
cov.trob(x, wt = rep(1, n), cor = FALSE, center = TRUE, nu = 5,
         maxit = 25, tol = 0.01)
```

**Arguments**

|                     |  |
|---------------------|--|
| <code>x</code>      | data matrix. Missing values (NAs) are not allowed.   |
| <code>wt</code>     | A vector of weights for each case: these are treated as if the case <code>i</code> actually occurred <code>wt[i]</code> times.   |
| <code>cor</code>    | Flag to choose between returning the correlation ( <code>cor = TRUE</code> ) or covariance ( <code>cor = FALSE</code> ) matrix.  |
| <code>center</code> | a logical value or a numeric vector providing the location about which the covariance is to be taken. If <code>center = FALSE</code> , no centering is done; if <code>center = TRUE</code> the MLE of the location vector is used. |
| <code>nu</code>     | 'degrees of freedom' for the multivariate t distribution. Must exceed 2 (so that the covariance matrix is finite).   |
| <code>maxit</code>  | Maximum number of iterations in fitting.   |
| <code>tol</code>    | Convergence tolerance for fitting.   |

**Value**

A list with the following components

|                     |   |
|---------------------|---|
| <code>cov</code>    | the fitted covariance matrix.   |
| <code>center</code> | the estimated or specified location vector.                                     |
| <code>wt</code>     | the specified weights: only returned if the <code>wt</code> argument was given. |
| <code>n.obs</code>  | the number of cases used in the fitting.  |
| <code>cor</code>    | the fitted correlation matrix: only returned if <code>cor = TRUE</code> .       |
| <code>call</code>   | The matched call.   |
| <code>iter</code>   | The number of iterations used.  |

crabs

---

*Morphological Measurements on Leptograpsus Crabs*

---

### Description

The `crabs` data frame has 200 rows and 8 columns, describing 5 morphological measurements on 50 crabs each of two colour forms and both sexes, of the species *Leptograpsus variegatus* collected at Fremantle, W. Australia.

### Usage

```
crabs
```

### Format

This data frame contains the following columns:

`sp` species - "B" or "O" for blue or orange.

`sex` as it says.

`index` index 1 : 50 within each of the four groups.

`FL` frontal lobe size (mm).

`RW` rear width (mm).

`CL` carapace length (mm).

`CW` carapace width (mm).

`BD` body depth (mm).

Cushings

---

*Diagnostic Tests on Patients with Cushing's Syndrome*

---

### Description

Cushing's syndrome is a hypertensive disorder associated with over-secretion of cortisol by the adrenal gland. The observations are urinary excretion rates of two steroid metabolites.

### Usage

```
Cushings
```

**Format**

The Cushings data frame has 27 rows and 3 columns:

Tetrahydrocortisone urinary excretion rate (mg/24hr) of Tetrahydrocortisone.

Pregnanetriol urinary excretion rate (mg/24hr) of Pregnanetriol.

Type underlying type of syndrome, coded a (adenoma) , b (bilateral hyperplasia), c (carcinoma) or u for unknown.

---

denumerate

---

*Transform an Allowable Formula for 'loglm' into one for 'terms'*

---

## Description

[loglm](#) allows dimension numbers to be used in place of names in the formula. `denumerate` modifies such a formula into one that [terms](#) can process.

## Usage

```
denumerate(x)
```

## Arguments

`x` A formula conforming to the conventions of [loglm](#), that is, it may allow dimension numbers to stand in for names when specifying a log-linear model.

## Details

The model fitting function [loglm](#) fits log-linear models to frequency data using iterative proportional scaling. To specify the model the user must nominate the margins in the data that remain fixed under the log-linear model. It is convenient to allow the user to use dimension numbers, 1, 2, 3, ... for the first, second, third, ..., margins in a similar way to variable names. As the model formula has to be parsed by [terms](#), which treats 1 in a special way and requires parseable variable names, these formulae have to be modified by giving genuine names for these margin, or dimension numbers. `denumerate` replaces these numbers with names of a special form, namely `n` is replaced by `.vn`. This allows `terms` to parse the formula in the usual way.

## Value

A linear model formula like that presented, except that where dimension numbers, say `n`, have been used to specify fixed margins these are replaced by names of the form `.vn` which may be processed by `terms`.

dose.p

*Predict Doses for Binomial Assay model***Description**

Calibrate binomial assays, generalizing the calculation of LD50.

**Usage**

```
dose.p(obj, cf = 1:2, p = 0.5)
```

**Arguments**

|     |  |
|-----|--|
| obj | A fitted model object of class inheriting from "glm".                                  |
| cf  | The terms in the coefficient vector giving the intercept and coefficient of (log-)dose |
| p   | Probabilities at which to predict the dose needed.                                     |

**Value**

An object of class "glm.dose" giving the prediction (attribute "p" and standard error (attribute "SE") at each response probability.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Springer.

**Examples**

```
ldose <- rep(0:5, 2)
numdead <- c(1, 4, 9, 13, 18, 20, 0, 2, 6, 10, 12, 16)
sex <- factor(rep(c("M", "F"), c(6, 6)))
SF <- cbind(numdead, numalive = 20 - numdead)
budworm.lg0 <- glm(SF ~ sex + ldose - 1, family = binomial)

dose.p(budworm.lg0, cf = c(1,3), p = 1:3/4)
dose.p(update(budworm.lg0, family = binomial(link=probit)),
       cf = c(1,3), p = 1:3/4)
```

drivers

*Deaths of Car Drivers in Great Britain 1969-84***Description**

A regular time series giving the monthly totals of car drivers in Great Britain killed or seriously injured Jan 1969 to Dec 1984. Compulsory wearing of seat belts was introduced on 31 Jan 1983

**Usage**

```
drivers
```

---

dropterm

---

*Try All One-Term Deletions from a Model*

---

**Description**

Try fitting all models that differ from the current model by dropping a single term, maintaining marginality.

This function is generic; there exist methods for classes `lm` and `glm` and the default method will work for many other classes.

**Usage**

```
dropterm (object, ...)

## Default S3 method:
dropterm(object, scope, scale = 0, test = c("none", "Chisq"),
         k = 2, sorted = FALSE, trace = FALSE, ...)

## S3 method for class 'lm'
dropterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),
         k = 2, sorted = FALSE, ...)

## S3 method for class 'glm'
dropterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),
         k = 2, sorted = FALSE, trace = FALSE, ...)
```

**Arguments**

|                     |  |
|---------------------|--|
| <code>object</code> | A object fitted by some model-fitting function.  |
| <code>scope</code>  | a formula giving terms which might be dropped. By default, the model formula. Only terms that can be dropped and maintain marginality are actually tried.  |
| <code>scale</code>  | used in the definition of the AIC statistic for selecting the models, currently only for <code>lm</code> , <code>ao</code> and <code>glm</code> models. Specifying <code>scale</code> asserts that the residual standard error or dispersion is known.   |
| <code>test</code>   | should the results include a test statistic relative to the original model? The F test is only appropriate for <code>lm</code> and <code>ao</code> models, and perhaps for some over-dispersed <code>glm</code> models. The Chisq test can be an exact test ( <code>lm</code> models with known scale) or a likelihood-ratio test depending on the method. |
| <code>k</code>      | the multiple of the number of degrees of freedom used for the penalty. Only <code>k = 2</code> gives the genuine AIC: <code>k = log(n)</code> is sometimes referred to as BIC or SBC.  |

|        |  |
|--------|--|
| sorted | should the results be sorted on the value of AIC?                          |
| trace  | if TRUE additional information may be given on the fits as they are tried. |
| ...    | arguments passed to or from other methods.                                 |

Details

The definition of AIC is only up to an additive constant: when appropriate (lm models with specified scale) the constant is taken to be that used in Mallows' Cp statistic and the results are labelled accordingly.

Value

A table of class "anova" containing at least columns for the change in degrees of freedom and AIC (or Cp) for the models. Some methods will give further information, for example sums of squares, deviances, log-likelihoods and test statistics.

---

epil

*Seizure Counts for Epileptics*

---

**Description**

Thall and Vail (1990) give a data set on two-week seizure counts for 59 epileptics. The number of seizures was recorded for a baseline period of 8 weeks, and then patients were randomly assigned to a treatment group or a control group. Counts were then recorded for four successive two-week periods. The subject's age is the only covariate.

**Usage**

epil

### Format

This data frame has 236 rows and the following 9 columns:

`y` the count for the 2-week period.  
`trt` treatment, "placebo" or "progabide".  
`base` the counts in the baseline 8-week period.  
`age` subject's age, in years.  
`V4` 0/1 indicator variable of period 4.  
`subject` subject number, 1 to 59.  
`period` period, 1 to 4.  
`lbase` log-counts for the baseline period, centred to have zero mean.  
`lage` log-ages, centred to have zero mean.

eqsplot

*Plots with Geometrically Equal Scales***Description**

Version of a scatterplot with scales chosen to be equal on both axes, that is 1cm represents the same units on each

**Usage**

```
eqsplot(x, y, ratio = 1, tol = 0.04, uin, ...)
```

**Arguments**

|                    |   |
|--------------------|---|
| <code>x</code>     | vector of x values, or a 2-column matrix, or a list with components <code>x</code> and <code>y</code>   |
| <code>y</code>     | vector of y values  |
| <code>ratio</code> | desired ratio of units on the axes. Units on the y axis are drawn at <code>ratio</code> times the size of units on the x axis. Ignored if <code>uin</code> is specified and of length 2.                |
| <code>tol</code>   | proportion of white space at the margins of plot.   |
| <code>uin</code>   | desired values for the units-per-inch parameter. If of length 1, the desired units per inch on the x axis.  |
| <code>...</code>   | further arguments for <code>plot</code> and graphical parameters. Note that <code>par(xaxs="i", yaxs="i")</code> is enforced, and <code>xlim</code> and <code>ylim</code> will be adjusted accordingly. |

**Details**

Limits for the x and y axes are chosen so that they include the data. One of the sets of limits is then stretched from the midpoint to make the units in the ratio given by `ratio`. Finally both are stretched by  $1 + \text{tol}$  to move points away from the axes, and the points plotted.

**Value**

invisibly, the values of `uin` used for the plot.

**Side Effects**

performs the plot.

**Note**

This was originally written for S: R's `plot.window` has an argument `asp` with a similar effect (including to this function's `ratio`) and can be passed from the default `plot` function.

Arguments `ratio` and `uin` were suggested by Bill Dunlap.

farms*Ecological Factors in Farm Management*

---

## Description

The `farms` data frame has 20 rows and 4 columns. The rows are farms on the Dutch island of Terschelling and the columns are factors describing the management of grassland.

## Usage

```
farms
```

## Format

This data frame contains the following columns:

`Mois` Five levels of soil moisture – level 3 does not occur at these 20 farms.

`Manag` Grassland management type (SF = standard, BF = biological, HF = hobby farming, NM = nature conservation).

`Use` Grassland use (U1 = hay production, U2 = intermediate, U3 = grazing).

`Manure` Manure usage – classes C0 to C4.

## Examples

```
farms.mca <- mca(farms, abbrev = TRUE) # Use levels as names
eqscplot(farms.mca$cs, type = "n")
text(farms.mca$rs, cex = 0.7)
text(farms.mca$cs, labels = dimnames(farms.mca$cs)[[1]], cex = 0.7)
```

fgl

*Measurements of Forensic Glass Fragments***Description**

The `fgl` data frame has 214 rows and 10 columns. It was collected by B. German on fragments of glass collected in forensic work.

**Usage**

fgl

**Format**

This data frame contains the following columns:

RI refractive index; more precisely the refractive index is 1.518xxxx.

The next 8 measurements are percentages by weight of oxides.

Na sodium.

Mg manganese.

Al aluminium.

Si silicon.

K potassium.

Ca calcium.

Ba barium.

Fe iron.

`type` The fragments were originally classed into seven types, one of which was absent in this dataset. The categories which occur are window float glass (`WinF`: 70), window non-float glass (`WinNF`: 76), vehicle window glass (`Veh`: 17), containers (`Con`: 13), tableware (`Tabl`: 9) and vehicle headlamps (`Head`: 29).

**References**

fitdistr

*Maximum-likelihood Fitting of Univariate Distributions***Description**

Maximum-likelihood fitting of univariate distributions, allowing parameters to be held fixed if desired.

**Usage**

```
fitdistr(x, densfun, start, ...)
```

## Arguments

|                      |   |
|----------------------|---|
| <code>x</code>       | A numeric vector of length at least one containing only <a href="#">finite</a> values.  |
| <code>densfun</code> | Either a character string or a function returning a density evaluated at its first argument.<br>Distributions "beta", "cauchy", "chi-squared", "exponential", "gamma", "geometric", "log-normal", "lognormal", "logistic", "negative binomial", "normal", "Poisson", "t" and "weibull" are recognised, case being ignored.                      |
| <code>start</code>   | A named list giving the parameters to be optimized with initial values. This can be omitted for some of the named distributions and must be for others (see Details).   |
| <code>...</code>     | Additional parameters, either for <code>densfun</code> or for <code>optim</code> . In particular, it can be used to specify bounds via <code>lower</code> or <code>upper</code> or both. If arguments of <code>densfun</code> (or the density function corresponding to a character-string specification) are included they will be held fixed. |

## Details

For the Normal, log-Normal, geometric, exponential and Poisson distributions the closed-form MLEs (and exact standard errors) are used, and `start` should not be supplied.

For all other distributions, direct optimization of the log-likelihood is performed using [optim](#). The estimated standard errors are taken from the observed information matrix, calculated by a numerical approximation. For one-dimensional problems the Nelder-Mead method is used and for multi-dimensional problems the BFGS method, unless arguments named `lower` or `upper` are supplied (when `L-BFGS-B` is used) or `method` is supplied explicitly.

For the "t" named distribution the density is taken to be the location-scale family with location `m` and scale `s`.

For the following named distributions, reasonable starting values will be computed if `start` is omitted or only partially specified: "cauchy", "gamma", "logistic", "negative binomial" (parametrized by `mu` and `size`), "t" and "weibull". Note that these starting values may not be good enough if the fit is poor: in particular they are not resistant to outliers unless the fitted distribution is long-tailed.

There are [print](#), [coef](#), [vcov](#) and [logLik](#) methods for class "fitdistr".

## Value

An object of class "fitdistr", a list with four components,

|                       |   |
|-----------------------|---|
| <code>estimate</code> | the parameter estimates,                      |
| <code>sd</code>       | the estimated standard errors,                |
| <code>vcov</code>     | the estimated variance-covariance matrix, and |
| <code>loglik</code>   | the log-likelihood.                           |

## Note

Numerical optimization cannot work miracles: please note the comments in [optim](#) on scaling data. If the fitted parameters are far away from one, consider re-fitting specifying the control parameter `parscale`.

## References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

## Examples

```
## avoid spurious accuracy
op <- options(digits = 3)
set.seed(123)
x <- rgamma(100, shape = 5, rate = 0.1)
fitdistr(x, "gamma")
## now do this directly with more control.
fitdistr(x, dgamma, list(shape = 1, rate = 0.1), lower = 0.001)

set.seed(123)
x2 <- rt(250, df = 9)
fitdistr(x2, "t", df = 9)
## allow df to vary: not a very good idea!
fitdistr(x2, "t")
## now do fixed-df fit directly with more control.
mydt <- function(x, m, s, df) dt((x-m)/s, df)/s
fitdistr(x2, mydt, list(m = 0, s = 1), df = 9, lower = c(-Inf, 0))

set.seed(123)
x3 <- rweibull(100, shape = 4, scale = 100)
fitdistr(x3, "weibull")

set.seed(123)
x4 <- rnegbin(500, mu = 5, theta = 4)
fitdistr(x4, "Negative Binomial")
options(op)
```

S. Weisberg (1980) *Applied Linear Regression*. Wiley.

fractions

*Rational Approximation***Description**

Find rational approximations to the components of a real numeric object using a standard continued fraction method.

**Usage**

```
fractions(x, cycles = 10, max.denominator = 2000, ...)
```

```
as.fractions(x)
```

```
is.fractions(f)
```

**Arguments**

|                              |   |
|------------------------------|---|
| <code>x</code>               | Any object of mode numeric. Missing values are now allowed.   |
| <code>cycles</code>          | The maximum number of steps to be used in the continued fraction approximation process.   |
| <code>max.denominator</code> | An early termination criterion. If any partial denominator exceeds <code>max.denominator</code> the continued fraction stops at that point. |
| <code>...</code>             | arguments passed to or from other methods.  |
| <code>f</code>               | an R object.  |

**Details**

Each component is first expanded in a continued fraction of the form

$$x = \text{floor}(x) + 1 / (p_1 + 1 / (p_2 + \dots))$$

where  $p_1, p_2, \dots$  are positive integers, terminating either at `cycles` terms or when a  $p_j > \text{max.denominator}$ . The continued fraction is then re-arranged to retrieve the numerator and denominator as integers.

The numerators and denominators are then combined into a character vector that becomes the "fracs" attribute and used in printed representations.

Arithmetic operations on "fractions" objects have full floating point accuracy, but the character representation printed out may not.

**Value**

An object of class "fractions". A structure with `.Data` component the same as the input numeric `x`, but with the rational approximations held as a character vector attribute, "fracs". Arithmetic operations on "fractions" objects are possible.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth Edition. Springer.

GAGurine

*Level of GAG in Urine of Children*

---

**Description**

Data were collected on the concentration of a chemical GAG in the urine of 314 children aged from zero to seventeen years. The aim of the study was to produce a chart to help a paediatrician to assess if a child's GAG concentration is 'normal'.

**Usage**

```
GAGurine
```

**Format**

This data frame contains the following columns:

Age age of child in years.

GAG concentration of GAG (the units have been lost).

**Source**

Mrs Susan Prosser, Paediatrics Department, University of Oxford, via Department of Statistics Consulting Service.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

galaxies

*Velocities for 82 Galaxies***Description**

A numeric vector of velocities in km/sec of 82 galaxies from 6 well-separated conic sections of an unfilled survey of the Corona Borealis region. Multimodality in such surveys is evidence for voids and superclusters in the far universe.

**Usage**

galaxies

**Note**

There is an 83rd measurement of 5607 km/sec in the Postman *et al.* paper which is omitted in Roeder (1990) and from the dataset here.

There is also a typo: this dataset has 78th observation 26690 which should be 26960.

**Source**

Roeder, K. (1990) Density estimation with confidence sets exemplified by superclusters and voids in galaxies. *Journal of the American Statistical Association* **85**, 617–624.

Postman, M., Huchra, J. P. and Geller, M. J. (1986) Probes of large-scale structures in the Corona Borealis region. *Astronomical Journal* **92**, 1238–1247.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

**Examples**

```
gal <- galaxies/1000
c(width.SJ(gal, method = "dpi"), width.SJ(gal))
plot(x = c(0, 40), y = c(0, 0.3), type = "n", bty = "l",
      xlab = "velocity of galaxy (1000km/s)", ylab = "density")
rug(gal)
lines(density(gal, width = 3.25, n = 200), lty = 1)
lines(density(gal, width = 2.56, n = 200), lty = 3)
```

gamma.dispersion

*Calculate the MLE of the Gamma Dispersion Parameter in a GLM Fit***Description**

A front end to `gamma.shape` for convenience. Finds the reciprocal of the estimate of the shape parameter only.

**Usage**

```
gamma.dispersion(object, ...)
```

**Arguments**

|        |  |
|--------|--|
| object | Fitted model object giving the gamma fit.                    |
| ...    | Additional arguments passed on to <code>gamma.shape</code> . |

**Value**

The MLE of the dispersion parameter of the gamma distribution.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

**See Also**

[gamma.shape.glm](#), including the example on its help page.

---

|             |  |
|-------------|--|
| gamma.shape | <i>Estimate the Shape Parameter of the Gamma Distribution in a GLM Fit</i> |
|-------------|--|

---

**Description**

Find the maximum likelihood estimate of the shape parameter of the gamma distribution after fitting a Gamma generalized linear model.

**Usage**

```
gamma.shape(object, ...)
```

```
## S3 method for class 'glm'
gamma.shape(object, it.lim = 10,
            eps.max = .Machine$double.eps^0.25, verbose = FALSE, ...)
```

**Arguments**

|         |   |
|---------|---|
| object  | Fitted model object from a Gamma family or quasi family with <code>variance = "mu^2"</code> .             |
| it.lim  | Upper limit on the number of iterations.  |
| eps.max | Maximum discrepancy between approximations for the iteration process to continue.                         |
| verbose | If TRUE, causes successive iterations to be printed out. The initial estimate is taken from the deviance. |
| ...     | further arguments passed to or from other methods.  |

**Details**

A glm fit for a Gamma family correctly calculates the maximum likelihood estimate of the mean parameters but provides only a crude estimate of the dispersion parameter. This function takes the results of the glm fit and solves the maximum likelihood equation for the reciprocal of the dispersion parameter, which is usually called the shape (or exponent) parameter.

**Value**

List of two components

`alpha` the maximum likelihood estimate

`SE` the approximate standard error, the square-root of the reciprocal of the observed information.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

gehan

*Remission Times of Leukaemia Patients*

---

**Description**

A data frame from a trial of 42 leukaemia patients. Some were treated with the drug *6-mercaptopurine* and the rest are controls. The trial was designed as matched pairs, both withdrawn from the trial when either came out of remission.

**Usage**

gehan

**Format**

This data frame contains the following columns:

`pair` label for pair.

`time` remission time in weeks.

`cens` censoring, 0/1.

`treat` treatment, control or 6-MP.

### Source

Cox, D. R. and Oakes, D. (1984) *Analysis of Survival Data*. Chapman & Hall, p. 7. Taken from

### Examples

```
library(survival)
gehan.surv <- survfit(Surv(time, cens) ~ treat, data = gehan,
  conf.type = "log-log")
summary(gehan.surv)
survreg(Surv(time, cens) ~ factor(pair) + treat, gehan, dist = "exponential")
summary(survreg(Surv(time, cens) ~ treat, gehan, dist = "exponential"))
summary(survreg(Surv(time, cens) ~ treat, gehan))
gehan.cox <- coxph(Surv(time, cens) ~ treat, gehan)
summary(gehan.cox)
```

---

genotype

*Rat Genotype Data*

---

### Description

Data from a foster feeding experiment with rat mothers and litters of four different genotypes: A, B, I and J. Rat litters were separated from their natural mothers at birth and given to foster mothers to rear.

### Usage

```
genotype
```

### Format

The data frame has the following components:

`Litter` genotype of the litter.

`Mother` genotype of the foster mother.

`Wt` Litter average weight gain of the litter, in grams at age 28 days. (The source states that the within-litter variability is negligible.)

---

geyser

---

*Old Faithful Geyser Data*

---

### Description

A version of the eruptions data from the ‘Old Faithful’ geyser in Yellowstone National Park, Wyoming. This version comes from Azzalini and Bowman (1990) and is of continuous measurement from August 1 to August 15, 1985.

Some nocturnal duration measurements were coded as 2, 3 or 4 minutes, having originally been described as ‘short’, ‘medium’ or ‘long’.

### Usage

```
geyser
```

### Format

A data frame with 299 observations on 2 variables.

|          |         |                                |
|----------|---------|--------------------------------|
| duration | numeric | Eruption time in mins          |
| waiting  | numeric | Waiting time for this eruption |

### Note

The `waiting` time was incorrectly described as the time to the next eruption in the original files, and corrected for **MASS** version 7.3-30.

---

gilgais

---

*Line Transect of Soil in Gilgai Territory*

---

### Description

This dataset was collected on a line transect survey in gilgai territory in New South Wales, Australia. Gilgais are natural gentle depressions in otherwise flat land, and sometimes seem to be regularly distributed. The data collection was stimulated by the question: are these patterns reflected in soil properties? At each of 365 sampling locations on a linear grid of 4 meters spacing, samples were taken at depths 0-10 cm, 30-40 cm and 80-90 cm below the surface. pH, electrical conductivity and chloride content were measured on a 1:5 soil:water extract from each sample.

**Usage**

```
gilgais
```

**Format**

This data frame contains the following columns:

```
pH00 pH at depth 0–10 cm.
pH30 pH at depth 30–40 cm.
pH80 pH at depth 80–90 cm.
e00  electrical conductivity in mS/cm (0–10 cm).
e30  electrical conductivity in mS/cm (30–40 cm).
e80  electrical conductivity in mS/cm (80–90 cm).
c00  chloride content in ppm (0–10 cm).
c30  chloride content in ppm (30–40 cm).
c80  chloride content in ppm (80–90 cm).
```

---

ginv

*Generalized Inverse of a Matrix*

---

**Description**

Calculates the Moore-Penrose generalized inverse of a matrix X.

**Usage**

```
ginv(X, tol = sqrt(.Machine$double.eps))
```

**Arguments**

```
X          Matrix for which the Moore-Penrose inverse is required.
tol        A relative tolerance to detect zero singular values.
```

**Value**

A MP generalized inverse matrix for X.

---

glm.convert

*Change a Negative Binomial fit to a GLM fit*

---

## Description

This function modifies an output object from `glm.nb()` to one that looks like the output from `glm()` with a negative binomial family. This allows it to be updated keeping the theta parameter fixed.

## Usage

```
glm.convert(object)
```

## Arguments

`object`            An object of class "negbin", typically the output from `glm.nb()`.

## Details

Convenience function needed to effect some low level changes to the structure of the fitted model object.

## Value

An object of class "glm" with negative binomial family. The theta parameter is then fixed at its present estimate.

## See Also

[glm.nb](#), [negative.binomial](#), [glm](#)

## Examples

```
quine.nb1 <- glm.nb(Days ~ Sex/(Age + Eth*Lrn), data = quine)
quine.nbA <- glm.convert(quine.nb1)
quine.nbB <- update(quine.nb1, . ~ . + Sex:Age:Lrn)
anova(quine.nbA, quine.nbB)
```

glm.nb

*Fit a Negative Binomial Generalized Linear Model***Description**

A modification of the system function `glm()` to include estimation of the additional parameter, `theta`, for a Negative Binomial generalized linear model.

**Usage**

```
glm.nb(formula, data, weights, subset, na.action,
       start = NULL, etastart, mustart,
       control = glm.control(...), method = "glm.fit",
       model = TRUE, x = FALSE, y = TRUE, contrasts = NULL, ...,
       init.theta, link = log)
```

**Arguments**

`formula`, `data`, `weights`, `subset`, `na.action`, `start`, `etastart`,  
`mustart`, `control`, `method`, `model`, `x`, `y`, `contrasts`, ...  
 arguments for the `glm()` function. Note that these exclude `family` and  
`offset` (but `offset()` can be used).

`init.theta` Optional initial value for the `theta` parameter. If omitted a moment estimator  
 after an initial fit using a Poisson GLM is used.

`link` The link function. Currently must be one of `log`, `sqrt` or `identity`.

**Details**

An alternating iteration process is used. For given `theta` the GLM is fitted using the same process as used by `glm()`. For fixed means the `theta` parameter is estimated using score and information iterations. The two are alternated until convergence of both. (The number of alternations and the number of iterations when estimating `theta` are controlled by the `maxit` parameter of `glm.control()`.)

Setting `trace > 0` traces the alternating iteration process. Setting `trace > 1` traces the `glm` fit, and setting `trace > 2` traces the estimation of `theta`.

**Value**

A fitted model object of class `negbin` inheriting from `glm` and `lm`. The object is like the output of `glm` but contains three additional components, namely `theta` for the ML estimate of `theta`, `SE.theta` for its approximate standard error (using observed rather than expected information), and `twologlik` for twice the log-likelihood function.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

**See Also**

`glm`, `negative.binomial`, `anova.negbin`, `summary.negbin`, `theta.md`

There is a `simulate` method.

**Examples**

```
quine.nb1 <- glm.nb(Days ~ Sex/(Age + Eth*Lrn), data = quine)
quine.nb2 <- update(quine.nb1, . ~ . + Sex:Age:Lrn)
quine.nb3 <- update(quine.nb2, Days ~ .^4)
anova(quine.nb1, quine.nb2, quine.nb3)
```

glmmPQL

*Fit Generalized Linear Mixed Models via PQL***Description**

Fit a GLMM model with multivariate normal random effects, using Penalized Quasi-Likelihood.

**Usage**

```
glmmPQL(fixed, random, family, data, correlation, weights,
        control, niter = 10, verbose = TRUE, ...)
```

**Arguments**

|                          |  |
|--------------------------|--|
| <code>fixed</code>       | a two-sided linear formula giving fixed-effects part of the model.   |
| <code>random</code>      | a formula or list of formulae describing the random effects.   |
| <code>family</code>      | a GLM family.  |
| <code>data</code>        | an optional data frame, list or environment used as the first place to find variables in the formulae, <code>weights</code> and if present in <code>...</code> , <code>subset</code> . |
| <code>correlation</code> | an optional correlation structure.   |
| <code>weights</code>     | optional case weights as in <code>glm</code> .   |
| <code>control</code>     | an optional argument to be passed to <code>lme</code> .  |
| <code>niter</code>       | maximum number of iterations.  |
| <code>verbose</code>     | logical: print out record of iterations?   |
| <code>...</code>         | Further arguments for <code>lme</code> .   |

**Details**

`glmmPQL` works by repeated calls to `lme`, so namespace **nlme** will be loaded at first use. (Before 2015 it used to attach `nlme` but nowadays only loads the namespace.)

Unlike `lme`, `offset` terms are allowed in `fixed` – this is done by pre- and post-processing the calls to `lme`.

Note that the returned object inherits from class `"lme"` and that most generics will use the method for that class. As from version 3.1-158, the fitted values have any offset included, as do the results of calling `predict`.

**Value**

A object of class `c("glmmPQL", "lme")`: see `lmeObject`.

immer

*Yields from a Barley Field Trial*

---

**Description**

The `immer` data frame has 30 rows and 4 columns. Five varieties of barley were grown in six locations in each of 1931 and 1932.

**Usage**

```
immer
```

**Format**

This data frame contains the following columns:

`Loc` The location.

`Var` The variety of barley ("manchuria", "svansota", "velvet", "trebi" and "peatland").

`Y1` Yield in 1931.

`Y2` Yield in 1932.

summary(immer.aov)

immer.aov <- aov((Y1+Y2)/2 ~ Var + Loc, data = immer)
summary(immer.aov)
model.tables(immer.aov, type = "means", se = TRUE, cterms = "Var")
```

---

Insurance

*Numbers of Car Insurance claims*

---

## Description

The data given in data frame `Insurance` consist of the numbers of policyholders of an insurance company who were exposed to risk, and the numbers of car insurance claims made by those policyholders in the third quarter of 1973.

## Usage

`Insurance`

## Format

This data frame contains the following columns:

`District` factor: district of residence of policyholder (1 to 4): 4 is major cities.

`Group` an ordered factor: group of car with levels <1 litre, 1–1.5 litre, 1.5–2 litre, >2 litre.

`Age` an ordered factor: the age of the insured in 4 groups labelled <25, 25–29, 30–35, >35.

`Holders` numbers of policyholders.

`Claims` numbers of claims

## References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S-PLUS*. Fourth Edition. Springer.

## Examples

```
## main-effects fit as Poisson GLM with offset
glm(Claims ~ District + Group + Age + offset(log(Holders)),
     data = Insurance, family = poisson)

# same via loglm
loglm(Claims ~ District + Group + Age + offset(log(Holders)),
      data = Insurance)
```

isoMDS

*Kruskal's Non-metric Multidimensional Scaling*

## Description

One form of non-metric multidimensional scaling

## Usage

```
isoMDS(d, y = cmdscale(d, k), k = 2, maxit = 50, trace = TRUE,
       tol = 1e-3, p = 2)
```

```
Shepard(d, x, p = 2)
```

## Arguments

|       |  |
|-------|--|
| d     | distance structure of the form returned by <code>dist</code> , or a full, symmetric matrix. Data are assumed to be dissimilarities or relative distances, but must be positive except for self-distance. Both missing and infinite values are allowed. |
| y     | An initial configuration. If none is supplied, <code>cmdscale</code> is used to provide the classical solution, unless there are missing or infinite dissimilarities.  |
| k     | The desired dimension for the solution, passed to <code>cmdscale</code> .  |
| maxit | The maximum number of iterations.  |
| trace | Logical for tracing optimization. Default <code>TRUE</code> .  |
| tol   | convergence tolerance.   |
| p     | Power for Minkowski distance in the configuration space.   |
| x     | A final configuration.   |

## Details

This chooses a  $k$ -dimensional (default  $k = 2$ ) configuration to minimize the stress, the square root of the ratio of the sum of squared differences between the input distances and those of the configuration to the sum of configuration distances squared. However, the input distances are allowed a monotonic transformation.

An iterative algorithm is used, which will usually converge in around 10 iterations. As this is necessarily an  $O(n^2)$  calculation, it is slow for large datasets. Further, since for the default  $p = 2$  the configuration is only determined up to rotations and reflections (by convention the centroid is at the origin), the result can vary considerably from machine to machine.

**Value**

Two components:

|                     |  |
|---------------------|--|
| <code>points</code> | A k-column vector of the fitted configuration. |
| <code>stress</code> | The final stress achieved (in percent).        |

**Side Effects**

If `trace` is true, the initial stress and the current stress are printed out every 5 iterations.

kde2d

---

*Two-Dimensional Kernel Density Estimation*

---

**Description**

Two-dimensional kernel density estimation with an axis-aligned bivariate normal kernel, evaluated on a square grid.

**Usage**

```
kde2d(x, y, h, n = 25, lims = c(range(x), range(y)))
```

**Arguments**

|                   |   |
|-------------------|---|
| <code>x</code>    | x coordinate of data  |
| <code>y</code>    | y coordinate of data  |
| <code>h</code>    | vector of bandwidths for x and y directions. Defaults to normal reference bandwidth (see <a href="#">bandwidth.nrd</a> ). A scalar value will be taken to apply to both directions. |
| <code>n</code>    | Number of grid points in each direction. Can be scalar or a length-2 integer vector.  |
| <code>lims</code> | The limits of the rectangle covered by the grid as <code>c(xl, xu, yl, yu)</code> .   |

**Value**

A list of three components.

|                   |  |
|-------------------|--|
| <code>x, y</code> | The x and y coordinates of the grid points, vectors of length <code>n</code> .   |
| <code>z</code>    | An <code>n[1]</code> by <code>n[2]</code> matrix of the estimated density: rows correspond to the value of <code>x</code> , columns to the value of <code>y</code> . |

**References**

detach("geyser")
```

---

 lda

*Linear Discriminant Analysis*

---

**Description**

Linear discriminant analysis.

**Usage**

```
lda(x, ...)

## S3 method for class 'formula'
lda(formula, data, ..., subset, na.action)

## Default S3 method:
```

```
lda(x, grouping, prior = proportions, tol = 1.0e-4,
    method, CV = FALSE, nu, ...)

## S3 method for class 'data.frame'
lda(x, ...)

## S3 method for class 'matrix'
lda(x, grouping, ..., subset, na.action)
```

### Arguments

|                        |   |
|------------------------|---|
| <code>formula</code>   | A formula of the form <code>groups ~ x1 + x2 + . . .</code> . That is, the response is the grouping factor and the right hand side specifies the (non-factor) discriminators.   |
| <code>data</code>      | An optional data frame, list or environment from which variables specified in <code>formula</code> are preferentially to be taken.  |
| <code>x</code>         | (required if no formula is given as the principal argument.) a matrix or data frame or Matrix containing the explanatory variables.   |
| <code>grouping</code>  | (required if no formula principal argument is given.) a factor specifying the class for each observation.   |
| <code>prior</code>     | the prior probabilities of class membership. If unspecified, the class proportions for the training set are used. If present, the probabilities should be specified in the order of the factor levels.  |
| <code>tol</code>       | A tolerance to decide if a matrix is singular; it will reject variables and linear combinations of unit-variance variables whose variance is less than <code>tol^2</code> .   |
| <code>subset</code>    | An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)  |
| <code>na.action</code> | A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is <code>na.omit</code> , which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.) |
| <code>method</code>    | "moment" for standard estimators of the mean and variance, "mle" for MLEs, "mve" to use <code>cov.mve</code> , or "t" for robust estimates based on a <i>t</i> distribution.  |
| <code>CV</code>        | If true, returns results (classes and posterior probabilities) for leave-one-out cross-validation. Note that if the prior is estimated, the proportions in the whole dataset are used.  |
| <code>nu</code>        | degrees of freedom for <code>method = "t"</code> .  |
| <code>. . .</code>     | arguments passed to or from other methods.  |

### Details

The function tries hard to detect if the within-class covariance matrix is singular. If any variable has within-group variance less than `tol^2` it will stop and report the variable as constant. This could result from poor scaling of the problem, but is more likely to result from constant variables.

Specifying the `prior` will affect the classification unless over-ridden in `predict.lda`. Unlike in most statistical packages, it will also affect the rotation of the linear discriminants within their space, as a weighted between-groups covariance matrix is used. Thus the first few linear discriminants emphasize the differences between groups with the weights given by the prior, which may differ from their prevalence in the dataset.

If one or more groups is missing in the supplied data, they are dropped with a warning, but the classifications produced are with respect to the original set of levels.

**Value**

If `CV = TRUE` the return value is a list with components `class`, the MAP classification (a factor), and `posterior`, posterior probabilities for the classes.

Otherwise it is an object of class `"lda"` containing the following components:

|                      |  |
|----------------------|--|
| <code>prior</code>   | the prior probabilities used.  |
| <code>means</code>   | the group means.   |
| <code>scaling</code> | a matrix which transforms observations to discriminant functions, normalized so that within groups covariance matrix is spherical.   |
| <code>svd</code>     | the singular values, which give the ratio of the between- and within-group standard deviations on the linear discriminant variables. Their squares are the canonical F-statistics. |
| <code>N</code>       | The number of observations used.   |
| <code>call</code>    | The (matched) function call.   |

**Note**

This function may be called giving either a formula and optional data frame, or a matrix and grouping factor as the first two arguments. All other arguments are optional, but `subset=` and `na.action=`, if required, must be fully named.

If a formula is given as the principal argument the object may be modified using `update()` in the usual way.

ldahist

*Histograms or Density Plots of Multiple Groups***Description**

Plot histograms or density plots of data on a single Fisher linear discriminant.

**Usage**

```
ldahist(data, g, nbins = 25, h, x0 = - h/1000, breaks,
        xlim = range(breaks), ymax = 0, width,
        type = c("histogram", "density", "both"),
        sep = (type != "density"),
        col = 5, xlab = deparse(substitute(data)), bty = "n", ...)
```

**Arguments**

|        |   |
|--------|---|
| data   | vector of data. Missing values (NAs) are allowed and omitted.   |
| g      | factor or vector giving groups, of the same length as data.   |
| nbins  | Suggested number of bins to cover the whole range of the data.  |
| h      | The bin width (takes precedence over nbins).  |
| x0     | Shift for the bins - the breaks are at $x_0 + h * (\dots, -1, 0, 1, \dots)$                                 |
| breaks | The set of breakpoints to be used. (Usually omitted, takes precedence over h and nbins).                    |
| xlim   | The limits for the x-axis.  |
| ymax   | The upper limit for the y-axis.   |
| width  | Bandwidth for density estimates. If missing, the Sheather-Jones selector is used for each group separately. |
| type   | Type of plot.   |
| sep    | Whether there is a separate plot for each group, or one combined plot.                                      |
| col    | The colour number for the bar fill.   |
| xlab   | label for the plot x-axis. By default, this will be the name of data.                                       |
| bty    | The box type for the plot - defaults to none.   |
| ...    | additional arguments to polygon.  |

**Side Effects**

Histogram and/or density plots are plotted on the current device.

leuk*Survival Times and White Blood Counts for Leukaemia Patients*

---

**Description**

A data frame of data from 33 leukaemia patients.

**Usage**

leuk

**Format**

A data frame with columns:

wbc white blood count.

ag a test result, "present" or "absent".

time survival time in weeks.

**Details**

Survival times are given for 33 patients who died from acute myelogenous leukaemia. Also measured was the patient's white blood cell count at the time of diagnosis. The patients were also factored into 2 groups according to the presence or absence of a morphologic characteristic of white blood cells. Patients termed AG positive were identified by the presence of Auer rods and/or significant granulation of the leukaemic cells in the bone marrow at the time of diagnosis.

**Examples**

```
library(survival)
plot(survfit(Surv(time) ~ ag, data = leuk), lty = 2:3, col = 2:3)

# now Cox models
leuk.cox <- coxph(Surv(time) ~ ag + log(wbc), leuk)
summary(leuk.cox)
```

lm.gls

*Fit Linear Models by Generalized Least Squares***Description**

Fit linear models by Generalized Least Squares

**Usage**

```
lm.gls(formula, data, W, subset, na.action, inverse = FALSE,
        method = "qr", model = FALSE, x = FALSE, y = FALSE,
        contrasts = NULL, ...)
```

**Arguments**

|           |  |
|-----------|--|
| formula   | a formula expression as for regression models, of the form <code>response ~ predictors</code> . See the documentation of <code>formula</code> for other details. |
| data      | an optional data frame, list or environment in which to interpret the variables occurring in <code>formula</code> .  |
| W         | a weight matrix.   |
| subset    | expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.                                      |
| na.action | a function to filter missing data.   |
| inverse   | logical: if true <code>W</code> specifies the inverse of the weight matrix: this is appropriate if a variance matrix is used.                                    |
| method    | method to be used by <code>lm.fit</code> .   |
| model     | should the model frame be returned?  |
| x         | should the design matrix be returned?  |
| y         | should the response be returned?   |
| contrasts | a list of contrasts to be used for some or all of  |
| ...       | additional arguments to <code>lm.fit</code> .  |

**Details**

The problem is transformed to uncorrelated form and passed to `lm.fit`.

**Value**

An object of class `"lm.gls"`, which is similar to an `"lm"` object. There is no `"weights"` component, and only a few `"lm"` methods will work correctly. As from version 7.1-22 the residuals and fitted values refer to the untransformed problem.

**See Also**

|----------|-------------------------|
| lm.ridge | <i>Ridge Regression</i> |
|----------|-------------------------|

---

## Description

Fit a linear model by ridge regression.

## Usage

```
lm.ridge(formula, data, subset, na.action, lambda = 0, model = FALSE,
          x = FALSE, y = FALSE, contrasts = NULL, ...)
select(obj)
```

## Arguments

|           |  |
|-----------|--|
| formula   | a formula expression as for regression models, of the form <code>response ~ predictors</code> . See the documentation of <code>formula</code> for other details. <a href="#">offset</a> terms are allowed. |
| data      | an optional data frame, list or environment in which to interpret the variables occurring in <code>formula</code> .  |
| subset    | expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.  |
| na.action | a function to filter missing data.   |
| lambda    | A scalar or vector of ridge constants.   |
| model     | should the model frame be returned? Not implemented.   |
| x         | should the design matrix be returned? Not implemented.   |
| y         | should the response be returned? Not implemented.  |
| contrasts | a list of contrasts to be used for some or all of factor terms in the formula. See the <code>contrasts.arg</code> of <a href="#">model.matrix.default</a> .  |
| ...       | additional arguments to <a href="#">lm.fit</a> .   |
| obj       | an R object, such as an "lm.ridge" fit.  |

## Details

If an intercept is present in the model, its coefficient is not penalized. (If you want to penalize an intercept, put in your own constant term and remove the intercept.)

## Value

A list with components

|        |   |
|--------|---|
| coef   | matrix of coefficients, one row for each value of <code>lambda</code> . Note that these are not on the original scale and are for use by the <a href="#">coef</a> method. |
| scales | scalings used on the X matrix.  |
| Inter  | was intercept included?   |
| lambda | vector of <code>lambda</code> values  |
| ym     | mean of y   |

|      |                                     |
|------|-------------------------------------|
| xm   | column means of x matrix            |
| GCV  | vector of GCV values                |
| kHKB | HKB estimate of the ridge constant. |
| kLW  | L-W estimate of the ridge constant. |

```

---

|       |  |
|-------|--|
| loglm | <i>Fit Log-Linear Models by Iterative Proportional Scaling</i> |
|-------|--|

---

Description

This function provides a front-end to the standard function, `loglin`, to allow log-linear models to be specified and fitted in a manner similar to that of other fitting functions, such as `glm`.

Usage

```
loglm(formula, data, subset, na.action, ...)
```

Arguments

|         |  |
|---------|--|
| formula | A linear model formula specifying the log-linear model.<br>If the left-hand side is empty, the <code>data</code> argument is required and must be a (complete) array of frequencies. In this case the variables on the right-hand side may be the names of the <code>dimnames</code> attribute of the frequency array, or may be the positive integers: 1, 2, 3, ... used as alternative names for the 1st, 2nd, 3rd, ... dimension (classifying factor). If the left-hand side is not empty it specifies a vector of frequencies. In this case the <code>data</code> argument, if present, must be a data frame from which the left-hand side vector and the classifying factors on the right-hand side are (preferentially) obtained. The usual abbreviation of a <code>.</code> to stand for 'all other variables in the data frame' is allowed. Any non-factors on the right-hand side of the formula are coerced to factor. |
| data    | Numeric array or data frame (or list or environment). In the first case it specifies the array of frequencies; in the second it provides the data frame from which the variables occurring in the formula are preferentially obtained in the usual way. This argument may be the result of a call to <a href="#">xtabs</a> .   |

|                        |   |
|------------------------|---|
| <code>subset</code>    | Specifies a subset of the rows in the data frame to be used. The default is to take all rows.               |
| <code>na.action</code> | Specifies a method for handling missing observations. The default is to fail if missing values are present. |
| <code>...</code>       | May supply other arguments to the function <code>loglm1</code> .  |

### Details

If the left-hand side of the formula is empty the `data` argument supplies the frequency array and the right-hand side of the formula is used to construct the list of fixed faces as required by `loglin`. Structural zeros may be specified by giving a `start` argument with those entries set to zero, as described in the help information for `loglin`.

If the left-hand side is not empty, all variables on the right-hand side are regarded as classifying factors and an array of frequencies is constructed. If some cells in the complete array are not specified they are treated as structural zeros. The right-hand side of the formula is again used to construct the list of faces on which the observed and fitted totals must agree, as required by `loglin`. Hence terms such as `a:b`, `a*b` and `a/b` are all equivalent.

### Value

An object of class "loglm" conveying the results of the fitted log-linear model. Methods exist for the generic functions `print`, `summary`, `deviance`, `fitted`, `coef`, `resid`, `anova` and `update`, which perform the expected tasks. Only log-likelihood ratio tests are allowed using `anova`.

The deviance is simply an alternative name for the log-likelihood ratio statistic for testing the current model within a saturated model, in accordance with standard usage in generalized linear models.

### Warning

If structural zeros are present, the calculation of degrees of freedom may not be correct. `loglin` itself takes no action to allow for structural zeros. `loglm` deducts one degree of freedom for each structural zero, but cannot make allowance for gains in error degrees of freedom due to loss of dimension in the model space. (This would require checking the rank of the model matrix, but since iterative proportional scaling methods are developed largely to avoid constructing the model matrix explicitly, the computation is at least difficult.)

When structural zeros (or zero fitted values) are present the estimated coefficients will not be available due to infinite estimates. The deviances will normally continue to be correct, though.

fm2 <- update(fm, .~.^3, print = TRUE)
## 5 iterations: deviation 0.075
anova(fm, fm1, fm2)

# Case 1. An array generated with xtabs.

loglm(~ Type + Origin, xtabs(~ Type + Origin, Cars93))

# Case 2. Frequencies given as a vector in a data frame
names(quine)
## [1] "Eth" "Sex" "Age" "Lrn" "Days"
fm <- loglm(Days ~ .^2, quine)
gm <- glm(Days ~ .^2, poisson, quine) # check glm.
c(deviance(fm), deviance(gm)) # deviances agree
## [1] 1368.7 1368.7
c(fm$df, gm$df) # resid df do not!
c(fm$df, gm$df.residual) # resid df do not!
## [1] 127 128
# The loglm residual degrees of freedom is wrong because of
# a non-detectable redundancy in the model matrix.
```

---

logtrans

---

*Estimate log Transformation Parameter*

---

## Description

Find and optionally plot the marginal (profile) likelihood for alpha for a transformation model of the form  $\log(y + \alpha) \sim x_1 + x_2 + \dots$

## Usage

```
logtrans(object, ...)

## Default S3 method:
logtrans(object, ..., alpha = seq(0.5, 6, by = 0.25) - min(y),
         plotit = TRUE, interp =, xlab = "alpha",
         ylab = "log Likelihood")

## S3 method for class 'formula'
logtrans(object, data, ...)

## S3 method for class 'lm'
logtrans(object, ...)
```

**Arguments**

|                     |  |
|---------------------|--|
| <code>object</code> | Fitted linear model object, or formula defining the untransformed model that is $y \sim x_1 + x_2 + \dots$ . The function is generic.  |
| <code>...</code>    | If <code>object</code> is a formula, this argument may specify a data frame as for <code>lm</code> .   |
| <code>alpha</code>  | Set of values for the transformation parameter, <code>alpha</code> .   |
| <code>plotit</code> | Should plotting be done?   |
| <code>interp</code> | Should the marginal log-likelihood be interpolated with a spline approximation? (Default is <code>TRUE</code> if plotting is to be done and the number of real points is less than 100.) |
| <code>xlab</code>   | as for <code>plot</code> .   |
| <code>ylab</code>   | as for <code>plot</code> .   |
| <code>data</code>   | optional <code>data</code> argument for <code>lm</code> fit.   |

**Value**

List with components `x` (for `alpha`) and `y` (for the marginal log-likelihood values).

**Side Effects**

A plot of the marginal log-likelihood is produced, if requested, together with an approximate mle and 95% confidence interval.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

**See Also**

[boxcox](#)

**Examples**

```
logtrans(Days ~ Age*Sex*Eth*Lrn, data = quine,
         alpha = seq(0.75, 6.5, length.out = 20))
```

---

lqs

---

*Resistant Regression*

---

**Description**

Fit a regression to the *good* points in the dataset, thereby achieving a regression estimator with a high breakdown point. `lmsreg` and `ltsreg` are compatibility wrappers.

**Usage**

```

lqs(x, ...)

## S3 method for class 'formula'
lqs(formula, data, ...,
     method = c("lts", "lqs", "lms", "S", "model.frame"),
     subset, na.action, model = TRUE,
     x.ret = FALSE, y.ret = FALSE, contrasts = NULL)

## Default S3 method:
lqs(x, y, intercept = TRUE, method = c("lts", "lqs", "lms", "S"),
     quantile, control = lqs.control(...), k0 = 1.548, seed, ...)

lmsreg(...)
ltsreg(...)

```

**Arguments**

|                                  |  |
|----------------------------------|--|
| <code>formula</code>             | a formula of the form $y \sim x_1 + x_2 + \dots$   |
| <code>data</code>                | an optional data frame, list or environment from which variables specified in <code>formula</code> are preferentially to be taken.   |
| <code>subset</code>              | an index vector specifying the cases to be used in fitting. (NOTE: If given, this argument must be named exactly.)   |
| <code>na.action</code>           | function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. Alternatives include <code>na.omit</code> and <code>na.exclude</code> , which lead to omission of cases with missing values on any required variable. (NOTE: If given, this argument must be named exactly.) |
| <code>model, x.ret, y.ret</code> | logical. If TRUE the model frame, the model matrix and the response are returned, respectively.  |
| <code>contrasts</code>           | an optional list. See the <code>contrasts.arg</code> of <code>model.matrix.default</code> .  |
| <code>x</code>                   | a matrix or data frame containing the explanatory variables.   |
| <code>y</code>                   | the response: a vector of length the number of rows of <code>x</code> .  |
| <code>intercept</code>           | should the model include an intercept?   |
| <code>method</code>              | the method to be used. <code>model.frame</code> returns the model frame: for the others see the Details section. Using <code>lmsreg</code> or <code>ltsreg</code> forces "lms" and "lts" respectively.   |
| <code>quantile</code>            | the quantile to be used: see Details. This is over-ridden if <code>method = "lms"</code> .   |
| <code>control</code>             | additional control items: see Details.   |
| <code>k0</code>                  | the cutoff / tuning constant used for $\chi()$ and $\psi()$ functions when <code>method = "S"</code> , currently corresponding to Tukey's 'biweight'.  |
| <code>seed</code>                | the seed to be used for random sampling: see <code>.Random.seed</code> . The current value of <code>.Random.seed</code> will be preserved if it is set.  |
| <code>...</code>                 | arguments to be passed to <code>lqs.default</code> or <code>lqs.control</code> , see <code>control</code> above and Details.   |

## Details

Suppose there are  $n$  data points and  $p$  regressors, including any intercept.

The first three methods minimize some function of the sorted squared residuals. For methods "lqs" and "lms" is the quantile squared residual, and for "lts" it is the sum of the quantile smallest squared residuals. "lqs" and "lms" differ in the defaults for quantile, which are  $\text{floor}((n+p+1)/2)$  and  $\text{floor}((n+1)/2)$  respectively. For "lts" the default is  $\text{floor}(n/2) + \text{floor}((p+1)/2)$ .

The "S" estimation method solves for the scale  $s$  such that the average of a function chi of the residuals divided by  $s$  is equal to a given constant.

The control argument is a list with components

**psamp:** the size of each sample. Defaults to  $p$ .

**nsamp:** the number of samples or "best" (the default) or "exact" or "sample". If "sample" the number chosen is  $\min(5 \cdot p, 3000)$ , taken from Rousseeuw and Hubert (1997). If "best" exhaustive enumeration is done up to 5000 samples; if "exact" exhaustive enumeration will be attempted however many samples are needed.

**adjust:** should the intercept be optimized for each sample? Defaults to TRUE.

## Value

An object of class "lqs". This is a list with components

|                      |  |
|----------------------|--|
| <b>crit</b>          | the value of the criterion for the best solution found, in the case of <code>method == "S"</code> before IWLS refinement.  |
| <b>sing</b>          | character. A message about the number of samples which resulted in singular fits.  |
| <b>coefficients</b>  | of the fitted linear model   |
| <b>bestone</b>       | the indices of those points fitted by the best sample found (prior to adjustment of the intercept, if requested).  |
| <b>fitted.values</b> | the fitted values.   |
| <b>residuals</b>     | the residuals.   |
| <b>scale</b>         | estimate(s) of the scale of the error. The first is based on the fit criterion. The second (not present for <code>method == "S"</code> ) is based on the variance of those residuals whose absolute value is less than 2.5 times the initial estimate. |

## Note

There seems no reason other than historical to use the lms and lqs options. LMS estimation is of low efficiency (converging at rate  $n^{-1/3}$ ) whereas LTS has the same asymptotic efficiency as an M estimator with trimming at the quartiles (Marazzi, 1993, p.201). LQS and LTS have the same maximal breakdown value of  $(\text{floor}((n-p)/2) + 1)/n$  attained if  $\text{floor}((n+p)/2) \leq \text{quantile} \leq \text{floor}((n+p+1)/2)$ . The only drawback mentioned of LTS is greater computation, as a sort was thought to be required (Marazzi, 1993, p.201) but this is not true as a partial sort can be used (and is used in this implementation).

Adjusting the intercept for each trial fit does need the residuals to be sorted, and may be significant extra computation if  $n$  is large and  $p$  small.

Opinions differ over the choice of psamp. Rousseeuw and Hubert (1997) only consider  $p$ ; Marazzi (1993) recommends  $p+1$  and suggests that more samples are better than adjustment for a given computational limit.

The computations are exact for a model with just an intercept and adjustment, and for LQS for a model with an intercept plus one regressor and exhaustive search with adjustment. For all other cases the minimization is only known to be approximate.

mca

---

*Multiple Correspondence Analysis*

---

**Description**

Computes a multiple correspondence analysis of a set of factors.

**Usage**

```
mca(df, nf = 2, abbrev = FALSE)
```

**Arguments**

|        |   |
|--------|---|
| df     | A data frame containing only factors  |
| nf     | The number of dimensions for the MCA. Rarely 3 might be useful.   |
| abbrev | Should the vertex names be abbreviated? By default these are of the form ‘factor.level’ but if <code>abbrev = TRUE</code> they are just ‘level’ which will suffice if the factors have distinct levels. |

**Value**

An object of class "mca", with components

|      |  |
|------|--|
| rs   | The coordinates of the rows, in <code>nf</code> dimensions.                                |
| cs   | The coordinates of the column vertices, one for each level of each factor.                 |
| fs   | Weights for each row, used to interpolate additional factors in <code>predict.mca</code> . |
| p    | The number of factors  |
| d    | The singular values for the <code>nf</code> dimensions.                                    |
| call | The matched call.  |

|----------|----------------------------------|
| menarche | <i>Age of Menarche in Warsaw</i> |
|----------|----------------------------------|

---

**Description**

Proportions of female children at various ages during adolescence who have reached menarche.

**Usage**

```
menarche
```

**Format**

This data frame contains the following columns:

Age Average age of the group. (The groups are reasonably age homogeneous.)

Total Total number of children in the group.

Menarche Number who have reached menarche.

**Source**

Milicer, H. and Szczotka, F. (1966) Age at Menarche in Warsaw girls in 1965. *Human Biology* **38**, 199–203.

The data are also given in

```
mprob <- glm(cbind(Menarche, Total - Menarche) ~ Age,
             binomial(link = probit), data = menarche)
```

---

 michelson

*Michelson's Speed of Light Data*

---

### Description

Measurements of the speed of light in air, made between 5th June and 2nd July, 1879. The data consists of five experiments, each consisting of 20 consecutive runs. The response is the speed of light in km/s, less 299000. The currently accepted value, on this scale of measurement, is 734.5.

### Usage

```
michelson
```

### Format

The data frame contains the following components:

`Expt` The experiment number, from 1 to 5.

`Run` The run number within each experiment.

`Speed` Speed-of-light measurement.

 minn38

*Minnesota High School Graduates of 1938*

---

### Description

The Minnesota high school graduates of 1938 were classified according to four factors, described below. The `minn38` data frame has 168 rows and 5 columns.

### Usage

```
minn38
```

### Format

This data frame contains the following columns:

`hs` high school rank: "L", "M" and "U" for lower, middle and upper third.

`phs` post high school status: Enrolled in college, ("C"), enrolled in non-collegiate school, ("N"), employed full-time, ("E") and other, ("O").

`fol` father's occupational level, (seven levels, "F1", "F2", ..., "F7").

`sex` sex: factor with levels "F" or "M".

`f` frequency.

motors

*Accelerated Life Testing of Motorettes*

---

**Description**

The `motors` data frame has 40 rows and 3 columns. It describes an accelerated life test at each of four temperatures of 10 motorettes, and has rather discrete times.

**Usage**

```
motors
```

**Format**

This data frame contains the following columns:

`temp` the temperature (degrees C) of the test.

`time` the time in hours to failure or censoring at 8064 hours (= 336 days).

`cens` an indicator variable for death.

# and predict at 130C
unlist(predict(motor.wei, data.frame(temp=130), se.fit = TRUE))

motor.cox <- coxph(Surv(time, cens) ~ temp, motors)
summary(motor.cox)
# predict at temperature 200
```

```
plot(survfit(motor.cox, newdata = data.frame(temp=200),
        conf.type = "log-log"))
summary(survfit(motor.cox, newdata = data.frame(temp=130)) )
```

muscle

*Effect of Calcium Chloride on Muscle Contraction in Rat Hearts*

## Description

The purpose of this experiment was to assess the influence of calcium in solution on the contraction of heart muscle in rats. The left auricle of 21 rat hearts was isolated and on several occasions a constant-length strip of tissue was electrically stimulated and dipped into various concentrations of calcium chloride solution, after which the shortening of the strip was accurately measured as the response.

## Usage

```
muscle
```

## Format

This data frame contains the following columns:

Strip which heart muscle strip was used?

Conc concentration of calcium chloride solution, in multiples of 2.2 mM.

Length the change in length (shortening) of the strip, (allegedly) in mm.

## Source

Linder, A., Chakravarti, I. M. and Vuagnat, P. (1964) Fitting asymptotic regression curves with different asymptotes. In *Contributions to Statistics. Presented to Professor P. C. Mahalanobis on the occasion of his 70th birthday*, ed. C. R. Rao, pp. 221–228. Oxford: Pergamon Press.

## References

  panel.xyplot(x, Muscle$logLength[subscripts], ...)
  llines(spline(x, y))
})

```

mvrnorm

*Simulate from a Multivariate Normal Distribution***Description**

Produces one or more samples from the specified multivariate normal distribution.

**Usage**

```
mvrnorm(n = 1, mu, Sigma, tol = 1e-6, empirical = FALSE, EISPACK = FALSE)
```

**Arguments**

|                        |   |
|------------------------|---|
| <code>n</code>         | the number of samples required.   |
| <code>mu</code>        | a vector giving the means of the variables.   |
| <code>Sigma</code>     | a positive-definite symmetric matrix specifying the covariance matrix of the variables.                                   |
| <code>tol</code>       | tolerance (relative to largest variance) for numerical lack of positive-definiteness in <code>Sigma</code> .              |
| <code>empirical</code> | logical. If true, <code>mu</code> and <code>Sigma</code> specify the empirical not population mean and covariance matrix. |
| <code>EISPACK</code>   | logical: values other than <code>FALSE</code> are an error.   |

**Details**

The matrix decomposition is done via `eigen`; although a Choleski decomposition might be faster, the eigendecomposition is stabler.

**Value**

If `n = 1` a vector of the same length as `mu`, otherwise an `n` by `length(mu)` matrix with one sample in each row.

**Side Effects**

Causes creation of the dataset `.Random.seed` if it does not already exist, otherwise its value is updated.

negative.binomial    *Family function for Negative Binomial GLMs*

---

## Description

Specifies the information required to fit a Negative Binomial generalized linear model, with known `theta` parameter, using `glm()`.

## Usage

```
negative.binomial(theta = stop("'theta' must be specified"), link = "log")
```

## Arguments

|                    |  |
|--------------------|--|
| <code>theta</code> | The known value of the additional parameter, <code>theta</code> .  |
| <code>link</code>  | The link function, as a character string, name or one-element character vector specifying one of <code>log</code> , <code>sqrt</code> or <code>identity</code> , or an object of class <code>"link-glm"</code> . |

## Value

An object of class `"family"`, a list of functions and expressions needed by `glm()` to fit a Negative Binomial generalized linear model.

## References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S-PLUS*. Fourth Edition. Springer.

```

newcomb

*Newcomb's Measurements of the Passage Time of Light***Description**

A numeric vector giving the 'Third Series' of measurements of the passage time of light recorded by Newcomb in 1882. The given values divided by 1000 plus 24.8 give the time in millionths of a second for light to traverse a known distance. The 'true' value is now considered to be 33.02.

The dataset is given in the order in Staudte and Sheather. Stigler (1977, Table 5) gives the dataset as

```
28 26 33 24 34 -44 27 16 40 -2 29 22 24 21 25 30 23 29 31 19
24 20 36 32 36 28 25 21 28 29 37 25 28 26 30 32 36 26 30 22
36 23 27 27 28 27 31 27 26 33 26 32 32 24 39 28 24 25 32 25
29 27 28 29 16 23
```

However, order is not relevant to its use as an example of robust estimation. (Thanks to Anthony Unwin for bringing this difference to our attention.)

**Usage**

```

nlsschools

*Eighth-Grade Pupils in the Netherlands***Description**

Snijders and Bosker (1999) use as a running example a study of 2287 eighth-grade pupils (aged about 11) in 132 classes in 131 schools in the Netherlands. Only the variables used in our examples are supplied.

**Usage**

```
nlsschools
```

### Format

This data frame contains 2287 rows and the following columns:

lang language test score.

IQ verbal IQ.

class class ID.

GS class size: number of eighth-grade pupils recorded in the class (there may be others: see COMB, and some may have been omitted with missing values).

SES social-economic status of pupil's family.

COMB were the pupils taught in a multi-grade class (0/1)? Classes which contained pupils from grades 7 and 8 are coded 1, but only eighth-graders were tested.

npk

---

*Classical N, P, K Factorial Experiment*

---

### Description

A classical N, P, K (nitrogen, phosphate, potassium) factorial experiment on the growth of peas conducted on 6 blocks. Each half of a fractional factorial design confounding the NPK interaction was used on 3 of the plots.

### Usage

npk

**Format**

The npk data frame has 24 rows and 5 columns:

block which block (label 1 to 6).

N indicator (0/1) for the application of nitrogen.

P indicator (0/1) for the application of phosphate.

K indicator (0/1) for the application of potassium.

yield Yield of peas, in pounds/plot (the plots were (1/70) acre).

**Note**

This dataset is also contained in R 3.0.2 and later.

Null

---

Null Spaces of Matrices

---

**Description**

Given a matrix, `M`, find a matrix `N` giving a basis for the (left) null space. That is `crossprod(N, M) = t(N) %*% M` is an all-zero matrix and `N` has the maximum number of linearly independent columns.

**Usage**

```
Null(M)
```

**Arguments**

`M` Input matrix. A vector is coerced to a 1-column matrix.

**Details**

For a basis for the (right) null space  $\{x : Mx = 0\}$ , use `Null(t(M))`.

**Value**

The matrix `N` with the basis for the (left) null space, or a matrix with zero columns if the matrix `M` is square and of maximal rank.

}
```

oats

*Data from an Oats Field Trial*

## Description

The yield of oats from a split-plot field trial using three varieties and four levels of manurial treatment. The experiment was laid out in 6 blocks of 3 main plots, each split into 4 sub-plots. The varieties were applied to the main plots and the manurial treatments to the sub-plots.

## Usage

oats

## Format

This data frame contains the following columns:

B Blocks, levels I, II, III, IV, V and VI.

V Varieties, 3 levels.

N Nitrogen (manurial) treatment, levels 0.0cwt, 0.2cwt, 0.4cwt and 0.6cwt, showing the application in cwt/acre.

Y Yields in 1/4lbs per sub-plot, each of area 1/80 acre.

OME

---

*Tests of Auditory Perception in Children with OME*

---

**Description**

Experiments were performed on children on their ability to differentiate a signal in broad-band noise. The noise was played from a pair of speakers and a signal was added to just one channel; the subject had to turn his/her head to the channel with the added signal. The signal was either coherent (the amplitude of the noise was increased for a period) or incoherent (independent noise was added for the same period to form the same increase in power).

The threshold used in the original analysis was the stimulus loudness needs to get 75% correct responses. Some of the children had suffered from otitis media with effusion (OME).

**Usage**

OME

**Format**

The OME data frame has 1129 rows and 7 columns:

ID Subject ID (1 to 99, with some IDs missing). A few subjects were measured at different ages.

OME "low" or "high" or "N/A" (at ages other than 30 and 60 months).

Age Age of the subject (months).

Loud Loudness of stimulus, in decibels.

Noise Whether the signal in the stimulus was "coherent" or "incoherent".

Correct Number of correct responses from Trials trials.

Trials Number of trials performed.

**Background**

The experiment was to study otitis media with effusion (OME), a very common childhood condition where the middle ear space, which is normally air-filled, becomes congested by a fluid. There is a concomitant fluctuating, conductive hearing loss which can result in various language, cognitive and social deficits. The term 'binaural hearing' is used to describe the listening conditions in which the brain is processing information from both ears at the same time. The brain computes differences in the intensity and/or timing of signals arriving at each ear which contributes to sound localisation and also to our ability to hear in background noise.

Some years ago, it was found that children of 7–8 years with a history of significant OME had significantly worse binaural hearing than children without such a history, despite having equivalent sensitivity. The question remained as to whether it was the timing, the duration, or the degree of

severity of the otitis media episodes during critical periods, which affected later binaural hearing. In an attempt to begin to answer this question, 95 children were monitored for the presence of effusion every month since birth. On the basis of OME experience in their first two years, the test population was split into one group of high OME prevalence and one of low prevalence.

## End(Not run)

```

**Description**

The subjective assessment, on a 0 to 20 integer scale, of 54 classical painters. The painters were assessed on four characteristics: composition, drawing, colour and expression. The data is due to the Eighteenth century art critic, de Piles.

**Usage**

```
painters
```

**Format**

The row names of the data frame are the painters. The components are:

Composition Composition score.

Drawing Drawing score.

Colour Colour score.

Expression Expression score.

School The school to which a painter belongs, as indicated by a factor level code as follows:  
 "A": Renaissance; "B": Mannerist; "C": Seicento; "D": Venetian; "E": Lombard; "F":  
 Sixteenth Century; "G": Seventeenth Century; "H": French.

---

```
pairs.lda
```

---

*Produce Pairwise Scatterplots from an 'lda' Fit*

---

**Description**

Pairwise scatterplot of the data on the linear discriminants.

**Usage**

```
## S3 method for class 'lda'
pairs(x, labels = colnames(x), panel = panel.llda,
      dimen, abbrev = FALSE, ..., cex=0.7, type = c("std", "trellis"))
```

Arguments

|        |   |
|--------|---|
| x      | Object of class "lda".  |
| labels | vector of character strings for labelling the variables.  |
| panel  | panel function to plot the data in each panel.  |
| dimen  | The number of linear discriminants to be used for the plot; if this exceeds the number determined by x the smaller value is used. |
| abbrev | whether the group labels are abbreviated on the plots. If abbrev > 0 this gives minlength in the call to abbreviate.              |
| ...    | additional arguments for pairs.default.   |
| cex    | graphics parameter cex for labels on plots.   |
| type   | type of plot. The default is in the style of pairs.default; the style "trellis" uses the Trellis function splom.                  |

Details

This function is a method for the generic function pairs() for class "lda". It can be invoked by calling pairs(x) for an object x of the appropriate class, or directly by calling pairs.lda(x) regardless of the class of the object.

ir <- rbind(iris3[, , 1], iris3[, , 2], iris3[, , 3])
parcoord(log(ir)[, c(3, 4, 2, 1)], col = 1 + (0:149)%/%50)
```

---

petrol

---

*N. L. Prater's Petrol Refinery Data*

---

**Description**

The yield of a petroleum refining process with four covariates. The crude oil appears to come from only 10 distinct samples.

These data were originally used by Prater (1956) to build an estimation equation for the yield of the refining process of crude oil to gasoline.

**Usage**

```
petrol
```

**Format**

The variables are as follows

No crude oil sample identification label. (Factor.)

SG specific gravity, degrees API. (Constant within sample.)

VP vapour pressure in pounds per square inch. (Constant within sample.)

V10 volatility of crude; ASTM 10% point. (Constant within sample.)

EP desired volatility of gasoline. (The end point. Varies within sample.)

Y yield as a percentage of crude.

**Source**

N. H. Prater (1956) Estimate gasoline yields from crudes. *Petroleum Refiner* **35**, 236–238.

This dataset is also given in D. J. Hand, F. Daly, K. McConway, D. Lunn and E. Ostrowski (eds) (1994) *A Handbook of Small Data Sets*. Chapman & Hall.

---

Pima.tr

*Diabetes in Pima Indian Women*

---

## Description

A population of women who were at least 21 years old, of Pima Indian heritage and living near Phoenix, Arizona, was tested for diabetes according to World Health Organization criteria. The data were collected by the US National Institute of Diabetes and Digestive and Kidney Diseases. We used the 532 complete records after dropping the (mainly missing) data on serum insulin.

## Usage

```
Pima.tr
Pima.tr2
Pima.te
```

## Format

These data frames contains the following columns:

```
npreg number of pregnancies.
glu plasma glucose concentration in an oral glucose tolerance test.
bp diastolic blood pressure (mm Hg).
skin triceps skin fold thickness (mm).
bmi body mass index (weight in kg/(height in m)2).
ped diabetes pedigree function.
age age in years.
type Yes or No, for diabetic according to WHO criteria.
```

## Details

The training set `Pima.tr` contains a randomly selected set of 200 subjects, and `Pima.te` contains the remaining 332 subjects. `Pima.tr2` contains `Pima.tr` plus 100 subjects with missing values in the explanatory variables.

plot.lda

---

*Plot Method for Class 'lda'*

---

## Description

Plots a set of data on one, two or more linear discriminants.

## Usage

```
## S3 method for class 'lda'
plot(x, panel = panel.lda, ..., cex = 0.7, dimen,
      abbrev = FALSE, xlab = "LD1", ylab = "LD2")
```

## Arguments

|        |   |
|--------|---|
| x      | An object of class "lda".   |
| panel  | the panel function used to plot the data.   |
| ...    | additional arguments to <code>pairs</code> , <code>ldahist</code> or <code>eqscplot</code> .  |
| cex    | graphics parameter <code>cex</code> for labels on plots.  |
| dimen  | The number of linear discriminants to be used for the plot; if this exceeds the number determined by <code>x</code> the smaller value is used.    |
| abbrev | whether the group labels are abbreviated on the plots. If <code>abbrev &gt; 0</code> this gives <code>minlength</code> in the call to abbreviate. |
| xlab   | label for the x axis  |
| ylab   | label for the y axis  |

## Details

This function is a method for the generic function `plot()` for class "lda". It can be invoked by calling `plot(x)` for an object `x` of the appropriate class, or directly by calling `plot.lda(x)` regardless of the class of the object.

The behaviour is determined by the value of `dimen`. For `dimen > 2`, a `pairs` plot is used. For `dimen = 2`, an equiscaled scatter plot is drawn. For `dimen = 1`, a set of histograms or density plots are drawn. Use argument `type` to match "histogram" or "density" or "both".

```

---

polr

---

*Ordered Logistic or Probit Regression*

---

### Description

Fits a logistic or probit regression model to an ordered factor response. The default logistic case is *proportional odds logistic regression*, after which the function is named.

### Usage

```
polr(formula, data, weights, start, ..., subset, na.action,
      contrasts = NULL, Hess = FALSE, model = TRUE,
      method = c("logistic", "probit", "loglog", "cloglog", "cauchit"))
```

## Arguments

|                        |  |
|------------------------|--|
| <code>formula</code>   | a formula expression as for regression models, of the form <code>response ~ predictors</code> . The response should be a factor (preferably an ordered factor), which will be interpreted as an ordinal response, with levels ordered as in the factor. The model must have an intercept: attempts to remove one will lead to a warning and be ignored. An offset may be used. See the documentation of <a href="#">formula</a> for other details. |
| <code>data</code>      | an optional data frame, list or environment in which to interpret the variables occurring in <code>formula</code> .  |
| <code>weights</code>   | optional case weights in fitting. Default to 1.  |
| <code>start</code>     | initial values for the parameters. This is in the format <code>c(coefficients, zeta)</code> : see the Values section.  |
| <code>...</code>       | additional arguments to be passed to <a href="#">optim</a> , most often a <code>control</code> argument.   |
| <code>subset</code>    | expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.  |
| <code>na.action</code> | a function to filter missing data.   |
| <code>contrasts</code> | a list of contrasts to be used for some or all of the factors appearing as variables in the model formula.   |
| <code>Hess</code>      | logical for whether the Hessian (the observed information matrix) should be returned. Use this if you intend to call <code>summary</code> or <code>vcov</code> on the fit.   |
| <code>model</code>     | logical for whether the model matrix should be returned.   |
| <code>method</code>    | logistic or probit or (complementary) log-log or <code>cauchit</code> (corresponding to a Cauchy latent variable).   |

## Details

This model is what Agresti (2002) calls a *cumulative link* model. The basic interpretation is as a *coarsened* version of a latent variable  $Y_i$  which has a logistic or normal or extreme-value or Cauchy distribution with scale parameter one and a linear model for the mean. The ordered factor which is observed is which bin  $Y_i$  falls into with breakpoints

$$\zeta_0 = -\infty < \zeta_1 < \dots < \zeta_K = \infty$$

This leads to the model

$$\text{logit}P(Y \leq k|x) = \zeta_k - \eta$$

with *logit* replaced by *probit* for a normal latent variable, and  $\eta$  being the linear predictor, a linear function of the explanatory variables (with no intercept). Note that it is quite common for other software to use the opposite sign for  $\eta$  (and hence the coefficients `beta`).

In the logistic case, the left-hand side of the last display is the log odds of category  $k$  or less, and since these are log odds which differ only by a constant for different  $k$ , the odds are proportional. Hence the term *proportional odds logistic regression*.

The log-log and complementary log-log links are the increasing functions  $F^{-1}(p) = -\log(-\log(p))$  and  $F^{-1}(p) = \log(-\log(1 - p))$ ; some call the first the ‘negative log-log’ link. These correspond to a latent variable with the extreme-value distribution for the maximum and minimum respectively.

A *proportional hazards* model for grouped survival times can be obtained by using the complementary log-log link with grouping ordered by increasing times.

[predict](#), [summary](#), [vcov](#), [anova](#), [model.frame](#) and an `extractAIC` method for use with [stepAIC](#) (and [step](#)). There are also [profile](#) and [confint](#) methods.

**Value**

A object of class "polr". This has components

|                            |  |
|----------------------------|--|
| <code>coefficients</code>  | the coefficients of the linear predictor, which has no intercept.  |
| <code>zeta</code>          | the intercepts for the class boundaries.   |
| <code>deviance</code>      | the residual deviance.   |
| <code>fitted.values</code> | a matrix, with a column for each level of the response.  |
| <code>lev</code>           | the names of the response levels.  |
| <code>terms</code>         | the <code>terms</code> structure describing the model.   |
| <code>df.residual</code>   | the number of residual degrees of freedoms, calculated using the weights.  |
| <code>edf</code>           | the (effective) number of degrees of freedom used by the model   |
| <code>n, nobs</code>       | the (effective) number of observations, calculated using the weights. ( <code>nobs</code> is for use by <a href="#">stepAIC</a> ). |
| <code>call</code>          | the matched call.  |
| <code>method</code>        | the matched method used.   |
| <code>convergence</code>   | the convergence code returned by <code>optim</code> .  |
| <code>niter</code>         | the number of function and gradient evaluations used by <code>optim</code> .   |
| <code>lp</code>            | the linear predictor (including any offset).   |
| <code>Hessian</code>       | (if <code>Hess</code> is true). Note that this is a numerical approximation derived from the optimization proces.                  |
| <code>model</code>         | (if <code>model</code> is true).   |

**Note**

The [vcov](#) method uses the approximate Hessian: for reliable results the model matrix should be sensibly scaled with all columns having range the order of one.

Prior to version 7.3-32, `method = "cloglog"` confusingly gave the log-log link, implicitly assuming the first response level was the 'best'.

|                 |  |
|-----------------|--|
| predict.glmmPQL | <i>Predict Method for glmmPQL Fits</i> |
|-----------------|--|

---

## Description

Obtains predictions from a fitted generalized linear model with random effects.

## Usage

```
## S3 method for class 'glmmPQL'
predict(object, newdata = NULL, type = c("link", "response"),
        level, na.action = na.pass, ...)
```

## Arguments

|           |   |
|-----------|---|
| object    | a fitted object of class inheriting from "glmmPQL".   |
| newdata   | optionally, a data frame in which to look for variables with which to predict.  |
| type      | the type of prediction required. The default is on the scale of the linear predictors; the alternative "response" is on the scale of the response variable. Thus for a default binomial model the default predictions are of log-odds (probabilities on logit scale) and type = "response" gives the predicted probabilities. |
| level     | an optional integer vector giving the level(s) of grouping to be used in obtaining the predictions. Level values increase from outermost to innermost grouping, with level zero corresponding to the population predictions. Defaults to the highest or innermost level of grouping.  |
| na.action | function determining what should be done with missing values in newdata. The default is to predict NA.  |
| ...       | further arguments passed to or from other methods.  |

## Value

If level is a single integer, a vector otherwise a data frame.

## See Also

[glmmPQL](#), [predict.lme](#).

## Examples

```
fit <- glmmPQL(y ~ trt + I(week > 2), random = ~1 | ID,
              family = binomial, data = bacteria)
predict(fit, bacteria, level = 0, type="response")
predict(fit, bacteria, level = 1, type="response")
```

---

predict.lda

*Classify Multivariate Observations by Linear Discrimination*

---

## Description

Classify multivariate observations in conjunction with `lda`, and also project data onto the linear discriminants.

## Usage

```
## S3 method for class 'lda'
predict(object, newdata, prior = object$prior, dimen,
        method = c("plug-in", "predictive", "debiased"), ...)
```

## Arguments

|                      |  |
|----------------------|--|
| <code>object</code>  | object of class "lda"  |
| <code>newdata</code> | data frame of cases to be classified or, if <code>object</code> has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If <code>newdata</code> is missing, an attempt will be made to retrieve the data used to fit the <code>lda</code> object.                |
| <code>prior</code>   | The prior probabilities of the classes, by default the proportions in the training set or what was set in the call to <code>lda</code> .   |
| <code>dimen</code>   | the dimension of the space to be used. If this is less than <code>min(p, ng-1)</code> , only the first <code>dimen</code> discriminant components are used (except for <code>method="predictive"</code> ), and only those dimensions are returned in <code>x</code> .  |
| <code>method</code>  | This determines how the parameter estimation is handled. With "plug-in" (the default) the usual unbiased parameter estimates are used and assumed to be correct. With "debiased" an unbiased estimator of the log posterior probabilities is used, and with "predictive" the parameter estimates are integrated out using a vague prior. |
| <code>...</code>     | arguments based from or to other methods   |

## Details

This function is a method for the generic function `predict()` for class "lda". It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.lda(x)` regardless of the class of the object.

Missing values in `newdata` are handled by returning `NA` if the linear discriminants cannot be evaluated. If `newdata` is omitted and the `na.action` of the fit omitted cases, these will be omitted on the prediction.

This version centres the linear discriminants so that the weighted mean (weighted by `prior`) of the group centroids is at the origin.

**Value**

a list with components

|           |   |
|-----------|---|
| class     | The MAP classification (a factor)   |
| posterior | posterior probabilities for the classes                                     |
| x         | the scores of test cases on up to <code>dimen</code> discriminant variables |

| predict.lqs | <i>Predict from an lqs Fit</i> |
|-------------|--------------------------------|

---

**Description**

Predict from an resistant regression fitted by `lqs`.

**Usage**

```
## S3 method for class 'lqs'
predict(object, newdata, na.action = na.pass, ...)
```

**Arguments**

|           |  |
|-----------|--|
| object    | object inheriting from class "lqs"   |
| newdata   | matrix or data frame of cases to be predicted or, if <code>object</code> has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If <code>newdata</code> is missing, an attempt will be made to retrieve the data used to fit the <code>lqs</code> object. |
| na.action | function determining what should be done with missing values in <code>newdata</code> . The default is to predict NA.   |
| ...       | arguments to be passed from or to other methods.   |

**Details**

This function is a method for the generic function `predict()` for class `lqs`. It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.lqs(x)` regardless of the class of the object.

Missing values in `newdata` are handled by returning `NA` if the linear fit cannot be evaluated. If `newdata` is omitted and the `na.action` of the fit omitted cases, these will be omitted on the prediction.

**Value**

A vector of predictions.

predict.mca

*Predict Method for Class 'mca'*

---

**Description**

Used to compute coordinates for additional rows or additional factors in a multiple correspondence analysis.

**Usage**

```
## S3 method for class 'mca'
predict(object, newdata, type = c("row", "factor"), ...)
```

**Arguments**

|                      |   |
|----------------------|---|
| <code>object</code>  | An object of class <code>"mca"</code> , usually the result of a call to <code>mca</code> .  |
| <code>newdata</code> | A data frame containing <i>either</i> additional rows of the factors used to fit <code>object</code> <i>or</i> additional factors for the cases used in the original fit. |
| <code>type</code>    | Are predictions required for further rows or for new factors?   |
| <code>...</code>     | Additional arguments from <code>predict</code> : unused.  |

**Value**

If `type = "row"`, the coordinates for the additional rows.

If `type = "factor"`, the coordinates of the column vertices for the levels of the new factors.

## Description

Classify multivariate observations in conjunction with `qda`

## Usage

```
## S3 method for class 'qda'
predict(object, newdata, prior = object$prior,
        method = c("plug-in", "predictive", "debiased", "looCV"), ...)
```

## Arguments

|                      |  |
|----------------------|--|
| <code>object</code>  | object of class "qda"  |
| <code>newdata</code> | data frame of cases to be classified or, if <code>object</code> has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If <code>newdata</code> is missing, an attempt will be made to retrieve the data used to fit the <code>qda</code> object.  |
| <code>prior</code>   | The prior probabilities of the classes, by default the proportions in the training set or what was set in the call to <code>qda</code> .   |
| <code>method</code>  | This determines how the parameter estimation is handled. With "plug-in" (the default) the usual unbiased parameter estimates are used and assumed to be correct. With "debiased" an unbiased estimator of the log posterior probabilities is used, and with "predictive" the parameter estimates are integrated out using a vague prior. With "looCV" the leave-one-out cross-validation fits to the original dataset are computed and returned. |
| <code>...</code>     | arguments based from or to other methods   |

## Details

This function is a method for the generic function `predict()` for class "qda". It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.qda(x)` regardless of the class of the object.

Missing values in `newdata` are handled by returning `NA` if the quadratic discriminants cannot be evaluated. If `newdata` is omitted and the `na.action` of the fit omitted cases, these will be omitted on the prediction.

Value

a list with components

|           |   |
|-----------|---|
| class     | The MAP classification (a factor)       |
| posterior | posterior probabilities for the classes |

|                  |  |
|------------------|--|
| <code>qda</code> | <i>Quadratic Discriminant Analysis</i> |
|------------------|--|

---

Description

Quadratic discriminant analysis.

**Usage**

```

qda(x, ...)

## S3 method for class 'formula'
qda(formula, data, ..., subset, na.action)

## Default S3 method:
qda(x, grouping, prior = proportions,
    method, CV = FALSE, nu, ...)

## S3 method for class 'data.frame'
qda(x, ...)

## S3 method for class 'matrix'
qda(x, grouping, ..., subset, na.action)

```

**Arguments**

|           |   |
|-----------|---|
| formula   | A formula of the form <code>groups ~ x1 + x2 + ...</code> . That is, the response is the grouping factor and the right hand side specifies the (non-factor) discriminators.   |
| data      | An optional data frame, list or environment from which variables specified in <code>formula</code> are preferentially to be taken.  |
| x         | (required if no formula is given as the principal argument.) a matrix or data frame or Matrix containing the explanatory variables.   |
| grouping  | (required if no formula principal argument is given.) a factor specifying the class for each observation.   |
| prior     | the prior probabilities of class membership. If unspecified, the class proportions for the training set are used. If specified, the probabilities should be specified in the order of the factor levels.  |
| subset    | An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)  |
| na.action | A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is <code>na.omit</code> , which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.) |
| method    | "moment" for standard estimators of the mean and variance, "mle" for MLEs, "mve" to use <code>cov.mve</code> , or "t" for robust estimates based on a t distribution.   |
| CV        | If true, returns results (classes and posterior probabilities) for leave-out-out cross-validation. Note that if the prior is estimated, the proportions in the whole dataset are used.  |
| nu        | degrees of freedom for <code>method = "t"</code> .  |
| ...       | arguments passed to or from other methods.  |

**Details**

Uses a QR decomposition which will give an error message if the within-group variance is singular for any group.

**Value**

an object of class "qda" containing the following components:

|         |   |
|---------|---|
| prior   | the prior probabilities used.   |
| means   | the group means.  |
| scaling | for each group <i>i</i> , <code>scaling[, , i]</code> is an array which transforms observations so that within-groups covariance matrix is spherical. |
| ldet    | a vector of half log determinants of the dispersion matrix.   |
| lev     | the levels of the grouping factor.  |
| terms   | (if formula is a formula) an object of mode expression and class term summarizing the formula.  |
| call    | the (matched) function call.  |

unless `CV=TRUE`, when the return value is a list with components:

|           |   |
|-----------|---|
| class     | The MAP classification (a factor)       |
| posterior | posterior probabilities for the classes |

---

quine

*Absenteeism from School in Rural New South Wales*

---

**Description**

The quine data frame has 146 rows and 5 columns. Children from Walgett, New South Wales, Australia, were classified by Culture, Age, Sex and Learner status and the number of days absent from school in a particular school year was recorded.

**Usage**

quine

**Format**

This data frame contains the following columns:

Eth ethnic background: Aboriginal or Not, ("A" or "N").

Sex sex: factor with levels ("F" or "M").

Age age group: Primary ("F0"), or forms "F1", "F2" or "F3".

Lrn learner status: factor with levels Average or Slow learner, ("AL" or "SL").

Days days absent from school in the year.

Rabbit

---

*Blood Pressure in Rabbits*

---

**Description**

Five rabbits were studied on two occasions, after treatment with saline (control) and after treatment with the  $5-HT_3$  antagonist MDL 72222. After each treatment ascending doses of phenylbiguanide were injected intravenously at 10 minute intervals and the responses of mean blood pressure measured. The goal was to test whether the cardiogenic chemoreflex elicited by phenylbiguanide depends on the activation of  $5-HT_3$  receptors.

**Usage**

Rabbit

**Format**

This data frame contains 60 rows and the following variables:

BPchange change in blood pressure relative to the start of the experiment.

Dose dose of Phenylbiguanide in micrograms.

Run label of run ("C1" to "C5", then "M1" to "M5").

Treatment placebo or the  $5-HT_3$  antagonist MDL 72222.

Animal label of animal used ("R1" to "R5").

---

rational

*Rational Approximation*

---

### Description

Find rational approximations to the components of a real numeric object using a standard continued fraction method.

### Usage

```
rational(x, cycles = 10, max.denominator = 2000, ...)
```

### Arguments

|                              |   |
|------------------------------|---|
| <code>x</code>               | Any object of mode numeric. Missing values are now allowed.   |
| <code>cycles</code>          | The maximum number of steps to be used in the continued fraction approximation process.   |
| <code>max.denominator</code> | An early termination criterion. If any partial denominator exceeds <code>max.denominator</code> the continued fraction stops at that point. |
| <code>...</code>             | arguments passed to or from other methods.  |

### Details

Each component is first expanded in a continued fraction of the form

$$x = \text{floor}(x) + 1 / (p_1 + 1 / (p_2 + \dots))$$

where  $p_1, p_2, \dots$  are positive integers, terminating either at `cycles` terms or when a  $p_j > \text{max.denominator}$ . The continued fraction is then re-arranged to retrieve the numerator and denominator as integers and the ratio returned as the value.

### Value

A numeric object with the same attributes as `x` but with entries rational approximations to the values. This effectively rounds relative to the size of the object and replaces very small entries by zero.

### See Also

[fractions](#)

### Examples

```
X <- matrix(runif(25), 5, 5)
zapsmall(solve(X, X/5)) # print near-zeroes as zero
rational(solve(X, X/5))
```

---

`renumerate`*Convert a Formula Transformed by 'denumerate'*

---

### Description

`denumerate` converts a formula written using the conventions of `loglm` into one that `terms` is able to process. `renumerate` converts it back again to a form like the original.

### Usage

```
renumerate(x)
```

### Arguments

`x`                      A formula, normally as modified by `denumerate`.

### Details

This is an inverse function to `denumerate`. It is only needed since `terms` returns an expanded form of the original formula where the non-marginal terms are exposed. This expanded form is mapped back into a form corresponding to the one that the user originally supplied.

### Value

A formula where all variables with names of the form `.vn`, where `n` is an integer, converted to numbers, `n`, as allowed by the formula conventions of `loglm`.

### See Also

`denumerate`

### Examples

```
denumerate(~(1+2+3)^3 + a/b)
## ~ (.v1 + .v2 + .v3)^3 + a/b
renumerate(.Last.value)
## ~ (1 + 2 + 3)^3 + a/b
```

---

`rlm`*Robust Fitting of Linear Models*

---

### Description

Fit a linear model by robust regression using an M estimator.

**Usage**

```

rlm(x, ...)

## S3 method for class 'formula'
rlm(formula, data, weights, ..., subset, na.action,
     method = c("M", "MM", "model.frame"),
     wt.method = c("inv.var", "case"),
     model = TRUE, x.ret = TRUE, y.ret = FALSE, contrasts = NULL)

## Default S3 method:
rlm(x, y, weights, ..., w = rep(1, nrow(x)),
     init = "ls", psi = psi.huber,
     scale.est = c("MAD", "Huber", "proposal 2"), k2 = 1.345,
     method = c("M", "MM"), wt.method = c("inv.var", "case"),
     maxit = 20, acc = 1e-4, test.vec = "resid", lqs.control = NULL)

psi.huber(u, k = 1.345, deriv = 0)
psi.hampel(u, a = 2, b = 4, c = 8, deriv = 0)
psi.bisquare(u, c = 4.685, deriv = 0)

```

**Arguments**

|                        |   |
|------------------------|---|
| <code>formula</code>   | a formula of the form $y \sim x_1 + x_2 + \dots$  |
| <code>data</code>      | an optional data frame, list or environment from which variables specified in <code>formula</code> are preferentially to be taken.  |
| <code>weights</code>   | a vector of prior weights for each case.  |
| <code>subset</code>    | An index vector specifying the cases to be used in fitting.   |
| <code>na.action</code> | A function to specify the action to be taken if NAs are found. The ‘factory-fresh’ default action in R is <code>na.omit</code> , and can be changed by <code>options(na.action=)</code> .   |
| <code>x</code>         | a matrix or data frame containing the explanatory variables.  |
| <code>y</code>         | the response: a vector of length the number of rows of <code>x</code> .   |
| <code>method</code>    | currently either M-estimation or MM-estimation or (for the <code>formula</code> method only) find the model frame. MM-estimation is M-estimation with Tukey’s bi-weight initialized by a specific S-estimator. See the ‘Details’ section.   |
| <code>wt.method</code> | are the weights case weights (giving the relative importance of case, so a weight of 2 means there are two of these) or the inverse of the variances, so a weight of two means this error is half as variable?  |
| <code>model</code>     | should the model frame be returned in the object?   |
| <code>x.ret</code>     | should the model matrix be returned in the object?  |
| <code>y.ret</code>     | should the response be returned in the object?  |
| <code>contrasts</code> | optional contrast specifications: see <code>lm</code> .   |
| <code>w</code>         | (optional) initial down-weighting for each case.  |
| <code>init</code>      | (optional) initial values for the coefficients OR a method to find initial values OR the result of a fit with a <code>coef</code> component. Known methods are <code>"ls"</code> (the default) for an initial least-squares fit using weights <code>w*weights</code> , and <code>"lts"</code> for an unweighted least-trimmed squares fit with 200 samples. |

|                          |   |
|--------------------------|---|
| <code>psi</code>         | the <code>psi</code> function is specified by this argument. It must give (possibly by name) a function <code>g(x, ..., deriv)</code> that for <code>deriv=0</code> returns <code>psi(x)/x</code> and for <code>deriv=1</code> returns <code>psi'(x)</code> . Tuning constants will be passed in via <code>...</code> |
| <code>scale.est</code>   | method of scale estimation: re-scaled MAD of the residuals (default) or Huber's proposal 2 (which can be selected by either "Huber" or "proposal 2").   |
| <code>k2</code>          | tuning constant used for Huber proposal 2 scale estimation.   |
| <code>maxit</code>       | the limit on the number of IWLS iterations.   |
| <code>acc</code>         | the accuracy for the stopping criterion.  |
| <code>test.vec</code>    | the stopping criterion is based on changes in this vector.  |
| <code>...</code>         | additional arguments to be passed to <code>rlm.default</code> or to the <code>psi</code> function.  |
| <code>lqs.control</code> | An optional list of control values for <code>lqs</code> .   |
| <code>u</code>           | numeric vector of evaluation points.  |
| <code>k, a, b, c</code>  | tuning constants.   |
| <code>deriv</code>       | 0 or 1: compute values of the <code>psi</code> function or of its first derivative.   |

### Details

Fitting is done by iterated re-weighted least squares (IWLS).

Psi functions are supplied for the Huber, Hampel and Tukey bisquare proposals as `psi.huber`, `psi.hampel` and `psi.bisquare`. Huber's corresponds to a convex optimization problem and gives a unique solution (up to collinearity). The other two will have multiple local minima, and a good starting point is desirable.

Selecting `method = "MM"` selects a specific set of options which ensures that the estimator has a high breakdown point. The initial set of coefficients and the final scale are selected by an S-estimator with  $k_0 = 1.548$ ; this gives (for  $n \gg p$ ) breakdown point 0.5. The final estimator is an M-estimator with Tukey's biweight and fixed scale that will inherit this breakdown point provided  $c > k_0$ ; this is true for the default value of  $c$  that corresponds to 95% relative efficiency at the normal. Case weights are not supported for `method = "MM"`.

### Value

An object of class `"rlm"` inheriting from `"lm"`. Note that the `df.residual` component is deliberately set to NA to avoid inappropriate estimation of the residual scale from the residual mean square by `"lm"` methods.

The additional components not in an `lm` object are

|                        |   |
|------------------------|---|
| <code>s</code>         | the robust scale estimate used  |
| <code>w</code>         | the weights used in the IWLS process                                  |
| <code>psi</code>       | the <code>psi</code> function with parameters substituted             |
| <code>conv</code>      | the convergence criteria at each iteration                            |
| <code>converged</code> | did the IWLS converge?  |
| <code>wresid</code>    | a working residual, weighted for <code>"inv.var"</code> weights only. |

### Note

Prior to version 7.3-52, offset terms in `formula` were omitted from fitted and predicted values.

---

rms.curv

*Relative Curvature Measures for Non-Linear Regression*

---

## Description

Calculates the root mean square parameter effects and intrinsic relative curvatures,  $c^\theta$  and  $c^t$ , for a fitted nonlinear regression, as defined in Bates & Watts, section 7.3, p. 253ff

## Usage

```
rms.curv(obj)
```

## Arguments

`obj` Fitted model object of class "nls". The model must be fitted using the default algorithm.

## Details

The method of section 7.3.1 of Bates & Watts is implemented. The function `deriv3` should be used generate a model function with first derivative (gradient) matrix and second derivative (Hessian) array attributes. This function should then be used to fit the nonlinear regression model.

A print method, `print.rms.curv`, prints the `pc` and `ic` components only, suitably annotated.

If either `pc` or `ic` exceeds some threshold (0.3 has been suggested) the curvature is unacceptably high for the planar assumption.

## Value

A list of class `rms.curv` with components `pc` and `ic` for parameter effects and intrinsic relative curvatures multiplied by  $\sqrt{F}$ , `ct` and `ci` for  $c^\theta$  and  $c^t$  (unmultiplied), and `C` the C-array as used in section 7.3.1 of Bates & Watts.

## Examples

```
# The treated sample from the Puromycin data
mmcurve <- deriv3(~ Vm * conc/(K + conc), c("Vm", "K"),
                  function(Vm, K, conc) NULL)
Treated <- Puromycin[Puromycin$state == "treated", ]
(Purfit1 <- nls(rate ~ mmcurve(Vm, K, conc), data = Treated,
                start = list(Vm=200, K=0.1)))
rms.curv(Purfit1)
##Parameter effects: c^theta x sqrt(F) = 0.2121
##                   Intrinsic: c^iota x sqrt(F) = 0.092
```

---

rnegbin

---

*Simulate Negative Binomial Variates*

---

## Description

Function to generate random outcomes from a Negative Binomial distribution, with mean  $\mu$  and variance  $\mu + \mu^2/\theta$ .

## Usage

```
rnegbin(n, mu = n, theta = stop("'theta' must be specified"))
```

## Arguments

|       |  |
|-------|--|
| n     | If a scalar, the number of sample values required. If a vector, <code>length(n)</code> is the number required and <code>n</code> is used as the mean vector if <code>mu</code> is not specified. |
| mu    | The vector of means. Short vectors are recycled.   |
| theta | Vector of values of the <code>theta</code> parameter. Short vectors are recycled.  |

## Details

The function uses the representation of the Negative Binomial distribution as a continuous mixture of Poisson distributions with Gamma distributed means. Unlike `rnbinom` the index can be arbitrary.

## Value

Vector of random Negative Binomial variate values.

## Side Effects

Changes `.Random.seed` in the usual way.

**Examples**

```
# Negative Binomials with means fitted(fm) and theta = 4.5
fm <- glm.nb(Days ~ ., data = quine)
dummy <- rnegbin(fitted(fm), theta = 4.5)
```

---

 sammon

---

*Sammon's Non-Linear Mapping*

---

**Description**

One form of non-metric multidimensional scaling.

**Usage**

```

sammon(d, y = cmdscale(d, k), k = 2, niter = 100, trace = TRUE,
       magic = 0.2, tol = 1e-4)

```

**Arguments**

|       |   |
|-------|---|
| d     | distance structure of the form returned by <code>dist</code> , or a full, symmetric matrix. Data are assumed to be dissimilarities or relative distances, but must be positive except for self-distance. This can contain missing values.   |
| y     | An initial configuration. If none is supplied, <code>cmdscale</code> is used to provide the classical solution. (If there are missing values in <code>d</code> , an initial configuration must be provided.) This must not have duplicates. |
| k     | The dimension of the configuration.   |
| niter | The maximum number of iterations.   |
| trace | Logical for tracing optimization. Default <code>TRUE</code> .   |
| magic | initial value of the step size constant in diagonal Newton method.  |
| tol   | Tolerance for stopping, in units of stress.   |

**Details**

This chooses a two-dimensional configuration to minimize the stress, the sum of squared differences between the input distances and those of the configuration, weighted by the distances, the whole sum being divided by the sum of input distances to make the stress scale-free.

An iterative algorithm is used, which will usually converge in around 50 iterations. As this is necessarily an  $O(n^2)$  calculation, it is slow for large datasets. Further, since the configuration is only determined up to rotations and reflections (by convention the centroid is at the origin), the result can vary considerably from machine to machine. In this release the algorithm has been modified by adding a step-length search (`magic`) to ensure that it always goes downhill.

**Value**

Two components:

|        |  |
|--------|--|
| points | A two-column vector of the fitted configuration. |
| stress | The final stress achieved.                       |

**Side Effects**

If `trace` is true, the initial stress and the current stress are printed out every 10 iterations.

ships

*Ships Damage Data*

---

## Description

Data frame giving the number of damage incidents and aggregate months of service by ship type, year of construction, and period of operation.

## Usage

ships

## Format

type type: "A" to "E".

year year of construction: 1960–64, 65–69, 70–74, 75–79 (coded as "60", "65", "70", "75").

period period of operation : 1960–74, 75–79.

service aggregate months of service.

incidents number of damage incidents.

shuttle*Space Shuttle Autolander Problem*

---

**Description**

The `shuttle` data frame has 256 rows and 7 columns. The first six columns are categorical variables giving example conditions; the seventh is the decision. The first 253 rows are the training set, the last 3 the test conditions.

**Usage**

```
shuttle
```

**Format**

This data frame contains the following factor columns:

`stability` stable positioning or not (`stab` / `xstab`).

`error` size of error (`MM` / `SS` / `LX` / `XL`).

`sign` sign of error, positive or negative (`pp` / `nn`).

`wind` wind sign (`head` / `tail`).

`magn` wind strength (`Light` / `Medium` / `Strong` / `Out of Range`).

`vis` visibility (`yes` / `no`).

`use` use the autolander or not. (`auto` / `noauto`.)

snails

*Snail Mortality Data*

---

### Description

Groups of 20 snails were held for periods of 1, 2, 3 or 4 weeks in carefully controlled conditions of temperature and relative humidity. There were two species of snail, A and B, and the experiment was designed as a 4 by 3 by 4 by 2 completely randomized design. At the end of the exposure time the snails were tested to see if they had survived; the process itself is fatal for the animals. The object of the exercise was to model the probability of survival in terms of the stimulus variables, and in particular to test for differences between species.

The data are unusual in that in most cases fatalities during the experiment were fairly small.

### Usage

```
snails
```

### Format

The data frame contains the following components:

Species snail species A (1) or B (2).

Exposure exposure in weeks.

Rel.Hum relative humidity (4 levels).

Temp temperature, in degrees Celsius (3 levels).

Deaths number of deaths.

N number of snails exposed.

---

 stepAIC
 

---

*Choose a model by AIC in a Stepwise Algorithm*

---

**Description**

Performs stepwise model selection by AIC.

**Usage**

```
stepAIC(object, scope, scale = 0,
        direction = c("both", "backward", "forward"),
        trace = 1, keep = NULL, steps = 1000, use.start = FALSE,
        k = 2, ...)
```

**Arguments**

object an object representing a model of an appropriate class. This is used as the initial model in the stepwise search.

scope defines the range of models examined in the stepwise search. This should be either a single formula, or a list containing components upper and lower, both formulae. See the details for how to specify the formulae and how they are used.

|           |  |
|-----------|--|
| scale     | used in the definition of the AIC statistic for selecting the models, currently only for <code>lm</code> and <code>aoV</code> models (see <code>extractAIC</code> for details).  |
| direction | the mode of stepwise search, can be one of "both", "backward", or "forward", with a default of "both". If the <code>scope</code> argument is missing the default for <code>direction</code> is "backward".   |
| trace     | if positive, information is printed during the running of <code>stepAIC</code> . Larger values may give more information on the fitting process.   |
| keep      | a filter function whose input is a fitted model object and the associated AIC statistic, and whose output is arbitrary. Typically <code>keep</code> will select a subset of the components of the object and return them. The default is not to keep anything. |
| steps     | the maximum number of steps to be considered. The default is 1000 (essentially as many as required). It is typically used to stop the process early.   |
| use.start | if true the updated fits are done starting at the linear predictor for the currently selected model. This may speed up the iterative calculations for <code>glm</code> (and other fits), but it can also slow them down. <b>Not used in R.</b>                 |
| k         | the multiple of the number of degrees of freedom used for the penalty. Only $k = 2$ gives the genuine AIC: $k = \log(n)$ is sometimes referred to as BIC or SBC.   |
| ...       | any additional arguments to <code>extractAIC</code> . (None are currently used.)   |

## Details

The set of models searched is determined by the `scope` argument. The right-hand-side of its `lower` component is always included in the model, and right-hand-side of the model is included in the upper component. If `scope` is a single formula, it specifies the upper component, and the lower model is empty. If `scope` is missing, the initial model is used as the upper model.

Models specified by `scope` can be templates to update `object` as used by `update.formula`.

There is a potential problem in using `glm` fits with a variable `scale`, as in that case the deviance is not simply related to the maximized log-likelihood. The `glm` method for `extractAIC` makes the appropriate adjustment for a gaussian family, but may need to be amended for other cases. (The `binomial` and `poisson` families have fixed `scale` by default and do not correspond to a particular maximum-likelihood problem for variable `scale`.)

Where a conventional deviance exists (e.g. for `lm`, `aoV` and `glm` fits) this is quoted in the analysis of variance table: it is the *unscaled* deviance.

## Value

the stepwise-selected model is returned, with up to two additional components. There is an "anova" component corresponding to the steps taken in the search, as well as a "keep" component if the `keep=` argument was supplied in the call. The "Resid. Dev" column of the analysis of deviance table refers to a constant minus twice the maximized log likelihood: it will be a deviance only in cases where a saturated model is well-defined (thus excluding `lm`, `aoV` and `survreg` fits, for example).

## Note

The model fitting must apply the models to the same dataset. This may be a problem if there are missing values and an `na.action` other than `na.fail` is used (as is the default in R). We suggest you remove the missing values first.

quine.nb2$anova
```

---

stormer

*The Stormer Viscometer Data*

---

## Description

The stormer viscometer measures the viscosity of a fluid by measuring the time taken for an inner cylinder in the mechanism to perform a fixed number of revolutions in response to an actuating weight. The viscometer is calibrated by measuring the time taken with varying weights while the mechanism is suspended in fluids of accurately known viscosity. The data comes from such a calibration, and theoretical considerations suggest a nonlinear relationship between time, weight and viscosity, of the form  $\text{Time} = (B1 * \text{Viscosity}) / (\text{Weight} - B2) + E$  where  $B1$  and  $B2$  are unknown parameters to be estimated, and  $E$  is error.

## Usage

```
stormer
```

**Format**

The data frame contains the following components:

Viscosity viscosity of fluid.

Wt actuating weight.

Time time taken.

**Source**

E. J. Williams (1959) *Regression Analysis*. Wiley.

summary.loglm*Summary Method Function for Objects of Class 'loglm'*

---

## Description

Returns a summary list for log-linear models fitted by iterative proportional scaling using `loglm`.

## Usage

```
## S3 method for class 'loglm'  
summary(object, fitted = FALSE, ...)
```

## Arguments

|                     |  |
|---------------------|--|
| <code>object</code> | a fitted <code>loglm</code> model object.  |
| <code>fitted</code> | if <code>TRUE</code> return observed and expected frequencies in the result. Using <code>fitted = TRUE</code> may necessitate re-fitting the object. |
| <code>...</code>    | arguments to be passed to or from other methods.   |

## Details

This function is a method for the generic function `summary()` for class `"loglm"`. It can be invoked by calling `summary(x)` for an object `x` of the appropriate class, or directly by calling `summary.loglm(x)` regardless of the class of the object.

## Value

a list is returned for use by `print.summary.loglm`. This has components

|                      |  |
|----------------------|--|
| <code>formula</code> | the formula used to produce <code>object</code>  |
| <code>tests</code>   | the table of test statistics (likelihood ratio, Pearson) for the fit.  |
| <code>oe</code>      | if <code>fitted = TRUE</code> , an array of the observed and expected frequencies, otherwise <code>NULL</code> . |

## References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

## See Also

[loglm](#), [summary](#)

---

|                |  |
|----------------|--|
| summary.negbin | <i>Summary Method Function for Objects of Class 'negbin'</i> |
|----------------|--|

---

## Description

Identical to `summary.glm`, but with three lines of additional output: the ML estimate of theta, its standard error, and twice the log-likelihood function.

## Usage

```
## S3 method for class 'negbin'
summary(object, dispersion = 1, correlation = FALSE, ...)
```

## Arguments

|             |   |
|-------------|---|
| object      | fitted model object of class <code>negbin</code> inheriting from <code>glm</code> and <code>lm</code> . Typically the output of <code>glm.nb</code> . |
| dispersion  | as for <code>summary.glm</code> , with a default of 1.  |
| correlation | as for <code>summary.glm</code> .   |
| ...         | arguments passed to or from other methods.  |

## Details

`summary.glm` is used to produce the majority of the output and supply the result. This function is a method for the generic function `summary()` for class `"negbin"`. It can be invoked by calling `summary(x)` for an object `x` of the appropriate class, or directly by calling `summary.negbin(x)` regardless of the class of the object.

## Value

As for `summary.glm`; the additional lines of output are not included in the resultant object.

## Side Effects

A summary table is produced as for `summary.glm`, with the additional information described above.

## References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

## IGNORE_RDIFF_END
```

summary.rlm

*Summary Method for Robust Linear Models***Description**

summary method for objects of class "rlm"

**Usage**

```
## S3 method for class 'rlm'
summary(object, method = c("XtX", "XtWX"), correlation = FALSE, ...)
```

**Arguments**

|             |   |
|-------------|---|
| object      | the fitted model. This is assumed to be the result of some fit that produces an object inheriting from the class <code>rlm</code> , in the sense that the components returned by the <code>rlm</code> function will be available. |
| method      | Should the weighted (by the IWLS weights) or unweighted cross-products matrix be used?  |
| correlation | logical. Should correlations be computed (and printed)?   |
| ...         | arguments passed to or from other methods.  |

**Details**

This function is a method for the generic function `summary()` for class "rlm". It can be invoked by calling `summary(x)` for an object `x` of the appropriate class, or directly by calling `summary.rlm(x)` regardless of the class of the object.

**Value**

If printing takes place, only a null value is returned. Otherwise, a list is returned with the following components. Printing always takes place if this function is invoked automatically as a method for the `summary` function.

|              |   |
|--------------|---|
| correlation  | The computed correlation coefficient matrix for the coefficients in the model.  |
| cov.unscaled | The unscaled covariance matrix; i.e, a matrix such that multiplying it by an estimate of the error variance produces an estimated covariance matrix for the coefficients. |
| sigma        | The scale estimate.   |
| stddev       | A scale estimate used for the standard errors.  |
| df           | The number of degrees of freedom for the model and for residuals.   |
| coefficients | A matrix with three columns, containing the coefficients, their standard errors and the corresponding t statistic.  |
| terms        | The terms object used in fitting this model.  |

**References**

survey

*Student Survey Data***Description**

This data frame contains the responses of 237 Statistics I students at the University of Adelaide to a number of questions.

**Usage**

```
survey
```

**Format**

The components of the data frame are:

**Sex** The sex of the student. (Factor with levels "Male" and "Female".)

**Wr.Hnd** span (distance from tip of thumb to tip of little finger of spread hand) of writing hand, in centimetres.

**NW.Hnd** span of non-writing hand.

**W.Hnd** writing hand of student. (Factor, with levels "Left" and "Right".)

**Fold** "Fold your arms! Which is on top" (Factor, with levels "R on L", "L on R", "Neither".)

**Pulse** pulse rate of student (beats per minute).

**Clap** 'Clap your hands! Which hand is on top?' (Factor, with levels "Right", "Left", "Neither".)

**Exer** how often the student exercises. (Factor, with levels "Freq" (frequently), "Some", "None".)

**Smoke** how much the student smokes. (Factor, levels "Heavy", "Regul" (regularly), "Occas" (occasionally), "Never".)

**Height** height of the student in centimetres.

**M.I** whether the student expressed height in imperial (feet/inches) or metric (centimetres/metres) units. (Factor, levels "Metric", "Imperial".)

**Age** age of the student in years.

---

`synth.tr`
*Synthetic Classification Problem*

---

### Description

The `synth.tr` data frame has 250 rows and 3 columns. The `synth.te` data frame has 100 rows and 3 columns. It is intended that `synth.tr` be used from training and `synth.te` for testing.

### Usage

```
synth.tr
synth.te
```

### Format

These data frames contains the following columns:

```
xs x-coordinate
ys y-coordinate
yc class, coded as 0 or 1.
```

### Source

Ripley, B.D. (1994) Neural networks and related methods for classification (with discussion). *Journal of the Royal Statistical Society series B* **56**, 409–456.

Ripley, B.D. (1996) *Pattern Recognition and Neural Networks*. Cambridge: Cambridge University Press.

---

`theta.md`
*Estimate theta of the Negative Binomial*

---

### Description

Given the estimated mean vector, estimate `theta` of the Negative Binomial Distribution.

### Usage

```
theta.md(y, mu, dfr, weights, limit = 20, eps = .Machine$double.eps^0.25)

theta.ml(y, mu, n, weights, limit = 10, eps = .Machine$double.eps^0.25,
         trace = FALSE)

theta.mm(y, mu, dfr, weights, limit = 10, eps = .Machine$double.eps^0.25)
```

**Arguments**

|                      |   |
|----------------------|---|
| <code>y</code>       | Vector of observed values from the Negative Binomial.   |
| <code>mu</code>      | Estimated mean vector.  |
| <code>n</code>       | Number of data points (defaults to the sum of <code>weights</code> )  |
| <code>dfr</code>     | Residual degrees of freedom (assuming <code>theta</code> known). For a weighted fit this is the sum of the weights minus the number of fitted parameters. |
| <code>weights</code> | Case weights. If missing, taken as 1.   |
| <code>limit</code>   | Limit on the number of iterations.  |
| <code>eps</code>     | Tolerance to determine convergence.   |
| <code>trace</code>   | logical: should iteration progress be printed?  |

**Details**

`theta.md` estimates by equating the deviance to the residual degrees of freedom, an analogue of a moment estimator.

`theta.ml` uses maximum likelihood.

`theta.mm` calculates the moment estimator of `theta` by equating the Pearson chi-square  $\sum (y - \mu)^2 / (\mu + \mu^2 / \theta)$  to the residual degrees of freedom.

**Value**

The required estimate of `theta`, as a scalar. For `theta.ml`, the standard error is given as attribute "SE".

**See Also**

[glm.nb](#)

**Examples**

```
quine.nb <- glm.nb(Days ~ .^2, data = quine)
theta.md(quine$Days, fitted(quine.nb), dfr = df.residual(quine.nb))
theta.ml(quine$Days, fitted(quine.nb))

```

---

topo

*Spatial Topographic Data*

---

### Description

The `topo` data frame has 52 rows and 3 columns, of topographic heights within a 310 feet square.

### Usage

```
topo
```

### Format

This data frame contains the following columns:

`x` x coordinates (units of 50 feet)

`y` y coordinates (units of 50 feet)

`z` heights (feet)

### Source

---

Traffic

*Effect of Swedish Speed Limits on Accidents*

---

### Description

An experiment was performed in Sweden in 1961–2 to assess the effect of a speed limit on the motorway accident rate. The experiment was conducted on 92 days in each year, matched so that day `j` in 1962 was comparable to day `j` in 1961. On some days the speed limit was in effect and enforced, while on other days there was no speed limit and cars tended to be driven faster. The speed limit days tended to be in contiguous blocks.

### Usage

```
Traffic
```

### Format

This data frame contains the following columns:

`year` 1961 or 1962.

`day` of year.

`limit` was there a speed limit?

`y` traffic accident count for that day.

|          |                         |
|----------|-------------------------|
| truehist | <i>Plot a Histogram</i> |
|----------|-------------------------|

---

## Description

Creates a histogram on the current graphics device.

## Usage

```
truehist(data, nbins = "Scott", h, x0 = -h/1000,
          breaks, prob = TRUE, xlim = range(breaks),
          ymax = max(est), col = "cyan",
          xlab = deparse(substitute(data)), bty = "n", ...)
```

## Arguments

|        |  |
|--------|--|
| data   | numeric vector of data for histogram. Missing values (NAs) are allowed and omitted.  |
| nbins  | The suggested number of bins. Either a positive integer, or a character string naming a rule: "Scott" or "Freedman-Diaconis" or "FD". (Case is ignored.)   |
| h      | The bin width, a strictly positive number (takes precedence over nbins).   |
| x0     | Shift for the bins - the breaks are at $x_0 + h * (\dots, -1, 0, 1, \dots)$  |
| breaks | The set of breakpoints to be used. (Usually omitted, takes precedence over h and nbins).   |
| prob   | If true (the default) plot a true histogram. The vertical axis has a <i>relative frequency density</i> scale, so the product of the dimensions of any panel gives the relative frequency. Hence the total area under the histogram is 1 and it is directly comparable with most other estimates of the probability density function. If false plot the counts in the bins. |
| xlim   | The limits for the x-axis.   |
| ymax   | The upper limit for the y-axis.  |
| col    | The colour for the bar fill: the default is colour 5 in the default R palette.   |
| xlab   | label for the plot x-axis. By default, this will be the name of data.  |
| bty    | The box type for the plot - defaults to none.  |
| ...    | additional arguments to <a href="#">rect</a> or <a href="#">plot</a> .   |

**Details**

This plots a true histogram, a density estimate of total area 1. If `breaks` is specified, those break-points are used. Otherwise if `h` is specified, a regular grid of bins is used with width `h`. If neither `breaks` nor `h` is specified, `nbins` is used to select a suitable `h`.

**Side Effects**

A histogram is plotted on the current device.

 ucv

*Unbiased Cross-Validation for Bandwidth Selection*

---

**Description**

Uses unbiased cross-validation to select the bandwidth of a Gaussian kernel density estimator.

**Usage**

```
ucv(x, nb = 1000, lower, upper)
```

**Arguments**

|                           |  |
|---------------------------|--|
| <code>x</code>            | a numeric vector   |
| <code>nb</code>           | number of bins to use.   |
| <code>lower, upper</code> | Range over which to minimize. The default is almost always satisfactory. |

**Value**

a bandwidth.

UScereal*Nutritional and Marketing Information on US Cereals*

---

**Description**

The UScereal data frame has 65 rows and 11 columns. The data come from the 1993 ASA Statistical Graphics Exposition, and are taken from the mandatory F&DA food label. The data have been normalized here to a portion of one American cup.

**Usage**

```
UScereal
```

**Format**

This data frame contains the following columns:

mfr Manufacturer, represented by its first initial: G=General Mills, K=Kelloggs, N=Nabisco, P=Post, Q=Quaker Oats, R=Ralston Purina.

calories number of calories in one portion.

protein grams of protein in one portion.

fat grams of fat in one portion.

sodium milligrams of sodium in one portion.

fibre grams of dietary fibre in one portion.

carbo grams of complex carbohydrates in one portion.

sugars grams of sugars in one portion.

shelf display shelf (1, 2, or 3, counting from the floor).

potassium grams of potassium.

vitamins vitamins and minerals (none, enriched, or 100%).

UScrime

*The Effect of Punishment Regimes on Crime Rates***Description**

Criminologists are interested in the effect of punishment regimes on crime rates. This has been studied using aggregate data on 47 states of the USA for 1960 given in this data frame. The variables seem to have been re-scaled to convenient numbers.

**Usage**

UScrime

**Format**

This data frame contains the following columns:

M percentage of males aged 14–24.  
 So indicator variable for a Southern state.  
 Ed mean years of schooling.  
 Po1 police expenditure in 1960.  
 Po2 police expenditure in 1959.  
 LF labour force participation rate.  
 M.F number of males per 1000 females.  
 Pop state population.  
 NW number of non-whites per 1000 people.  
 U1 unemployment rate of urban males 14–24.  
 U2 unemployment rate of urban males 35–39.  
 GDP gross domestic product per head.  
 Ineq income inequality.  
 Prob probability of imprisonment.  
 Time average time served in state prisons.  
 y rate of crimes in a particular category per head of population.

waders

*Counts of Waders at 15 Sites in South Africa***Description**

The `waders` data frame has 15 rows and 19 columns. The entries are counts of waders in summer.

**Usage**

`waders`

**Format**

This data frame contains the following columns (species)

S1 Oystercatcher  
 S2 White-fronted Plover  
 S3 Kitt Lutz's Plover  
 S4 Three-banded Plover  
 S5 Grey Plover  
 S6 Ringed Plover  
 S7 Bar-tailed Godwit  
 S8 Whimbrel  
 S9 Marsh Sandpiper  
 S10 Greenshank  
 S11 Common Sandpiper  
 S12 Turnstone  
 S13 Knot  
 S14 Sanderling  
 S15 Little Stint  
 S16 Curlew Sandpiper  
 S17 Ruff  
 S18 Avocet  
 S19 Black-winged Stilt

The rows are the sites:

A = Namibia North coast  
 B = Namibia North wetland  
 C = Namibia South coast  
 D = Namibia South wetland  
 E = Cape North coast  
 F = Cape North wetland  
 G = Cape West coast  
 H = Cape West wetland  
 I = Cape South coast  
 J = Cape South wetland  
 K = Cape East coast  
 L = Cape East wetland  
 M = Transkei coast  
 N = Natal coast  
 O = Natal wetland

---

whiteside*House Insulation: Whiteside's Data*

---

## Description

Mr Derek Whiteside of the UK Building Research Station recorded the weekly gas consumption and average external temperature at his own house in south-east England for two heating seasons, one of 26 weeks before, and one of 30 weeks after cavity-wall insulation was installed. The object of the exercise was to assess the effect of the insulation on gas consumption.

## Usage

whiteside

## Format

The whiteside data frame has 56 rows and 3 columns.:

Insul A factor, before or after insulation.

Temp Purportedly the average outside temperature in degrees Celsius. (These values is far too low for any 56-week period in the 1960s in South-East England. It might be the weekly average of daily minima.)

Gas The weekly gas consumption in 1000s of cubic feet.

## Source

A data set collected in the 1960s by Mr Derek Whiteside of the UK Building Research Station. Reported by

Hand, D. J., Daly, F., McConway, K., Lunn, D. and Ostrowski, E. eds (1993) *A Handbook of Small Data Sets*. Chapman & Hall, p. 69.

## References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

## Examples

```
require(lattice)
xyplot(Gas ~ Temp | Insul, whiteside, panel =
  function(x, y, ...) {
    panel.xyplot(x, y, ...)
    panel.lmline(x, y, ...)
  }, xlab = "Average external temperature (deg. C)",
  ylab = "Gas consumption (1000 cubic feet)", aspect = "xy",
  strip = function(...) strip.default(..., style = 1))

gasB <- lm(Gas ~ Temp, whiteside, subset = Insul=="Before")
gasA <- update(gasB, subset = Insul=="After")
summary(gasB)
summary(gasA)
gasBA <- lm(Gas ~ Insul/Temp - 1, whiteside)
summary(gasBA)
```

```
gasQ <- lm(Gas ~ Insul/(Temp + I(Temp^2)) - 1, whiteside)
coef(summary(gasQ))

gasPR <- lm(Gas ~ Insul + Temp, whiteside)
anova(gasPR, gasBA)
options(contrasts = c("contr.treatment", "contr.poly"))
gasBA1 <- lm(Gas ~ Insul*Temp, whiteside)
coef(summary(gasBA1))
```

width.SJ

*Bandwidth Selection by Pilot Estimation of Derivatives***Description**

Uses the method of Sheather & Jones (1991) to select the bandwidth of a Gaussian kernel density estimator.

**Usage**

```
width.SJ(x, nb = 1000, lower, upper, method = c("ste", "dpi"))
```

**Arguments**

|              |  |
|--------------|--|
| x            | a numeric vector   |
| nb           | number of bins to use.   |
| upper, lower | range over which to search for solution if method = "ste".       |
| method       | Either "ste" ("solve-the-equation") or "dpi" ("direct plug-in"). |

**Value**

a bandwidth.

**Note**

A faster version for large n (thousands) is available in  $R \geq 3.4.0$  as part of [bw.SJ](#): quadruple its value for comparability with this version.

**References**

width.SJ(galaxies)
```

---

write.matrix

---

Write a Matrix or Data Frame

---

**Description**

Writes a matrix or data frame to a file or the console, using column labels and a layout respecting columns.

**Usage**

```
write.matrix(x, file = "", sep = " ", blocksize)
```

**Arguments**

|           |   |
|-----------|---|
| x         | matrix or data frame.   |
| file      | name of output file. The default ("") is the console.   |
| sep       | The separator between columns.  |
| blocksize | If supplied and positive, the output is written in blocks of <code>blocksize</code> rows. Choose as large as possible consistent with the amount of memory available. |

**Details**

If `x` is a matrix, supplying `blocksize` is more memory-efficient and enables larger matrices to be written, but each block of rows might be formatted slightly differently.

If `x` is a data frame, the conversion to a matrix may negate the memory saving.

**Side Effects**

A formatted file is produced, with column headings (if `x` has them) and columns of data.

`wtloss`*Weight Loss Data from an Obese Patient*

---

**Description**

The data frame gives the weight, in kilograms, of an obese patient at 52 time points over an 8 month period of a weight rehabilitation programme.

**Usage**`wtloss`**Format**

This data frame contains the following columns:

`Days` time in days since the start of the programme.

`Weight` weight in kilograms of the patient.

**Source**

Dr T. Davies, Adelaide.

**References**

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

**Examples**

```
## IGNORE_RDIFF_BEGIN
wtloss.fm <- nls(Weight ~ b0 + b1*2^(-Days/th),
  data = wtloss, start = list(b0=90, b1=95, th=120))
wtloss.fm
## IGNORE_RDIFF_END
plot(wtloss)
with(wtloss, lines(Days, fitted(wtloss.fm)))
```

## Chapter 17

# The `Matrix` package

---

`abIndex-class`

*Class "abIndex" of Abstract Index Vectors*

---

### Description

The `"abIndex"` [class](#), short for “Abstract Index Vector”, is used for dealing with large index vectors more efficiently, than using integer (or [numeric](#)) vectors of the kind `2:1000000` or `c(0:1e5, 1000:1e6)`.

Note that the current implementation details are subject to change, and if you consider working with these classes, please contact the package maintainers (`packageDescription("Matrix")$Maintainer`).

### Objects from the Class

Objects can be created by calls of the form `new("abIndex", ...)`, but more easily and typically either by `as(x, "abIndex")` where `x` is an integer (valued) vector, or directly by `abIseq()` and combination `c(...)` of such.

### Slots

**kind:** a [character](#) string, one of `("int32", "double", "rleDiff")`, denoting the internal structure of the `abIndex` object.

**x:** Object of class `"numLike"`; is used (i.e., not of length 0) only iff the object is *not* compressed, i.e., currently exactly when `kind != "rleDiff"`.

**rleD:** object of class `"rleDiff"`, used for compression via [rle](#).

### Methods

**as.numeric, as.integer, as.vector** `signature(x = "abIndex"): ...`

`[ signature(x = "abIndex", i = "index", j = "ANY", drop = "ANY"): ...`

**coerce** `signature(from = "numeric", to = "abIndex"): ...`

**coerce** `signature(from = "abIndex", to = "numeric"): ...`

**coerce** `signature(from = "abIndex", to = "integer"): ...`

**length** `signature(x = "abIndex"): ...`

**Ops** signature(e1 = "numeric", e2 = "abIndex"): These and the following arithmetic and logic operations are **not yet implemented**; see [Ops](#) for a list of these (S4) group methods.

**Ops** signature(e1 = "abIndex", e2 = "abIndex"): ...

**Ops** signature(e1 = "abIndex", e2 = "numeric"): ...

**Summary** signature(x = "abIndex"): ...

**show** ("abIndex"): simple [show](#) method, building on `show(<rleDiff>)`.

**is.na** ("abIndex"): works analogously to regular vectors.

**is.finite, is.infinite** ("abIndex"): ditto.

## Note

This is currently experimental and not yet used for our own code. Please contact us (`packageDescription("Matrix")$Maintainer`), if you plan to make use of this class.

Partly builds on ideas and code from Jens Oehlschlaegel, as implemented (around 2008, in the GPL'ed part of) package `ff`.

## See Also

[rle \(base\)](#) which is used here; [numeric](#)

## Examples

```
showClass("abIndex")
ii <- c(-3:40, 20:70)
str(ai <- as(ii, "abIndex"))# note
ai # -> show() method

stopifnot(identical(-3:20,
                    as(abIseq1(-3,20), "vector")))
```

---

abIseq

*Sequence Generation of "abIndex", Abstract Index Vectors*

---

## Description

Generation of abstract index vectors, i.e., objects of class "[abIndex](#)".

`abIseq()` is designed to work entirely like [seq](#), but producing "abIndex" vectors.

`abIseq1()` is its basic building block, where `abIseq1(n,m)` corresponds to `n:m`.

`c(x, ...)` will return an "abIndex" vector, when `x` is one.

## Usage

```
abIseq1(from = 1, to = 1)
abIseq (from = 1, to = 1, by = ((to - from)/(length.out - 1)),
        length.out = NULL, along.with = NULL)

## S3 method for class 'abIndex'
c(...)
```

**Arguments**

|            |   |
|------------|---|
| from,to    | the starting and (maximal) end value of the sequence.   |
| by         | number: increment of the sequence.  |
| length.out | desired length of the sequence. A non-negative number, which for seq and seq.int will be rounded up if fractional.  |
| along.with | take the length from the length of this argument.   |
| ...        | in general an arbitrary number of R objects; here, when the first is an "abIndex" vector, these arguments will be concatenated to a new "abIndex" object. |

**Value**

An abstract index vector, i.e., object of class "abIndex".

**See Also**

the class `abIndex` documentation; `rep2abI()` for another constructor; `rle` (**base**).

**Examples**

```
stopifnot(identical(-3:20,
                    as(abIseq1(-3,20), "vector")))

try( ## (arithmetic) not yet implemented
abIseq(1, 50, by = 3)
)
```

---

all.equal-methods    *Matrix Package Methods for Function all.equal()*

---

**Description**

Methods for function `all.equal()` (from R package **base**) are defined for all `Matrix` classes.

**Methods**

```
target = "Matrix", current = "Matrix" \
target = "ANY", current = "Matrix" \
target = "Matrix", current = "ANY" these three methods are simply using
all.equal.numeric directly and work via as.vector().
```

There are more methods, notably also for "`sparseVector`"'s, see `showMethods("all.equal")`.

## Examples

```
showMethods("all.equal")

(A <- spMatrix(3,3, i= c(1:3,2:1), j=c(3:1,1:2), x = 1:5))
ex <- expand(lu. <- lu(A))
stopifnot( all.equal(as(A[lu.@p + 1L, lu.@q + 1L], "CsparseMatrix"),
                    lu.@L %*% lu.@U),
  with(ex, all.equal(as(P %*% A %*% t(Q), "CsparseMatrix"),
                    L %*% U)),
  with(ex, all.equal(as(A, "CsparseMatrix"),
                    t(P) %*% L %*% U %*% Q)))
```

asUniqueT

*Standardize a Sparse Matrix in Triplet Format*

## Description

Detect or standardize a [TsparseMatrix](#) with unsorted or duplicated  $(i, j)$  pairs.

## Usage

```
anyDuplicatedT(x, ...)
isUniqueT(x, byrow = FALSE, isT = is(x, "TsparseMatrix"))
asUniqueT(x, byrow = FALSE, isT = is(x, "TsparseMatrix"))
aggregateT(x)
```

## Arguments

|                    |   |
|--------------------|---|
| <code>x</code>     | an R object. <code>anyDuplicatedT</code> and <code>aggregateT</code> require <code>x</code> inheriting from <a href="#">TsparseMatrix</a> . <code>asUniqueT</code> requires <code>x</code> inheriting from <a href="#">Matrix</a> and coerces <code>x</code> to <a href="#">TsparseMatrix</a> if necessary. |
| <code>...</code>   | optional arguments passed to the default method for generic function <a href="#">anyDuplicated</a> .  |
| <code>byrow</code> | a logical indicating if <code>x</code> should be sorted by row then by column.  |
| <code>isT</code>   | a logical indicating if <code>x</code> inherits from virtual class <a href="#">TsparseMatrix</a> .  |

## Value

`anyDuplicatedT(x)` returns the index of the first duplicated  $(i, j)$  pair in `x` (0 if there are no duplicated pairs).

`isUniqueT(x)` returns TRUE if `x` is a [TsparseMatrix](#) with sorted, nonduplicated  $(i, j)$  pairs and FALSE otherwise.

`asUniqueT(x)` returns the unique [TsparseMatrix](#) representation of `x` with sorted, nonduplicated  $(i, j)$  pairs. Values corresponding to identical  $(i, j)$  pairs are aggregated by addition, where in the logical case “addition” refers to logical OR.

`aggregateT(x)` aggregates without sorting.

## See Also

Virtual class [TsparseMatrix](#).

## Examples

```

example("dgTMatrix-class", echo=FALSE)
## -> 'T2' with (i,j,x) slots of length 5 each
T2u <- asUniqueT(T2)
stopifnot(## They "are" the same (and print the same):
  all.equal(T2, T2u, tol=0),
  ## but not internally:
  anyDuplicatedT(T2) == 2,
  anyDuplicatedT(T2u) == 0,
  length(T2 @x) == 5,
  length(T2u@x) == 3)

isUniqueT(T2 ) # FALSE
isUniqueT(T2u) # TRUE

T3 <- T2u
T3[1, c(1,3)] <- 10; T3[2, c(1,5)] <- 20
T3u <- asUniqueT(T3)
str(T3u) # sorted in 'j', and within j, sorted in i
stopifnot(isUniqueT(T3u))

## Logical l.TMatrix and n.TMatrix :
(L2 <- T2 > 0)
validObject(L2u <- asUniqueT(L2))
(N2 <- as(L2, "nMatrix"))
validObject(N2u <- asUniqueT(N2))
stopifnot(N2u@i == L2u@i, L2u@i == T2u@i, N2@i == L2@i, L2@i == T2@i,
  N2u@j == L2u@j, L2u@j == T2u@j, N2@j == L2@j, L2@j == T2@j)
# now with a nasty NA [partly failed in Matrix 1.1-5]:
L.0N <- L.1N <- L2
L.0N@x[1:2] <- c(FALSE, NA)
L.1N@x[1:2] <- c(TRUE, NA)
validObject(L.0N)
validObject(L.1N)
(m.0N <- as.matrix(L.0N))
(m.1N <- as.matrix(L.1N))
stopifnot(identical(10L, which(is.na(m.0N))), !anyNA(m.1N))
symnum(m.0N)
symnum(m.1N)

```

## Description

Return the matrix obtained by setting to zero elements below a diagonal (`triu`), above a diagonal (`tril`), or outside of a general band (`band`).

## Usage

```

band(x, k1, k2, ...)
triu(x, k = 0L, ...)
tril(x, k = 0L, ...)

```

**Arguments**

|                        |  |
|------------------------|--|
| <code>x</code>         | a matrix-like object   |
| <code>k, k1, k2</code> | integers specifying the diagonals that are not set to zero, $k1 \leq k2$ . These are interpreted relative to the main diagonal, which is $k = 0$ . Positive and negative values of $k$ indicate diagonals above and below the main diagonal, respectively. |
| <code>...</code>       | optional arguments passed to methods, currently unused by package <b>Matrix</b> .  |

**Details**

`triu(x, k)` is equivalent to `band(x, k, dim(x)[2])`. Similarly, `tril(x, k)` is equivalent to `band(x, -dim(x)[1], k)`.

**Value**

An object of a suitable matrix class, inheriting from `triangularMatrix` where appropriate. It inherits from `sparseMatrix` if and only if `x` does.

**Methods**

`x = "CsparseMatrix"` method for compressed, sparse, column-oriented matrices.

`x = "RsparseMatrix"` method for compressed, sparse, row-oriented matrices.

`x = "TsparseMatrix"` method for sparse matrices in triplet format.

`x = "diagonalMatrix"` method for diagonal matrices.

`x = "denseMatrix"` method for dense matrices in packed or unpacked format.

`x = "matrix"` method for traditional matrices of implicit class `matrix`.

**See Also**

`bandSparse` for the *construction* of a banded sparse matrix directly from its non-zero diagonals.

**Examples**

```
## A random sparse matrix :
set.seed(7)
m <- matrix(0, 5, 5)
m[sample(length(m), size = 14)] <- rep(1:9, length=14)
(mm <- as(m, "CsparseMatrix"))

tril(mm)          # lower triangle
tril(mm, -1)      # strict lower triangle
triu(mm, 1)       # strict upper triangle
band(mm, -1, 2)   # general band
(m5 <- Matrix(rnorm(25), ncol = 5))
tril(m5)          # lower triangle
tril(m5, -1)      # strict lower triangle
triu(m5, 1)       # strict upper triangle
band(m5, -1, 2)   # general band
(m65 <- Matrix(rnorm(30), ncol = 5)) # not square
triu(m65)         # result not "dtrMatrix" unless square
(sm5 <- crossprod(m65)) # symmetric
  band(sm5, -1, 1) # "dsyMatrix": symmetric band preserves symmetry property
as(band(sm5, -1, 1), "sparseMatrix") # often preferable
(sm <- round(crossprod(triu(mm/2)))) # sparse symmetric ("dsC*")
```

```
band(sm, -1,1) # remains "dsC", *however*
band(sm, -2,1) # -> "dgC"
```

bandSparse

*Construct Sparse Banded Matrix from (Sup-/Super-) Diagonals***Description**

Construct a sparse banded matrix by specifying its non-zero sup- and super-diagonals.

**Usage**

```
bandSparse(n, m = n, k, diagonals, symmetric = FALSE,
           repr = "C", giveCsparse = (repr == "C"))
```

**Arguments**

|                          |  |
|--------------------------|--|
| <code>n, m</code>        | the matrix dimension $(n, m) = (nrow, ncol)$ .   |
| <code>k</code>           | integer vector of “diagonal numbers”, with identical meaning as in <code>band(*, k)</code> , i.e., relative to the main diagonal, which is $k=0$ .   |
| <code>diagonals</code>   | optional list of sub-/super- diagonals; if missing, the result will be a pattern matrix, i.e., inheriting from class <code>nMatrix</code> .<br><br>diagonals can also be $n' \times d$ matrix, where $d \leftarrow \text{length}(k)$ and $n' \geq \min(n, m)$ . In that case, the sub-/super- diagonals are taken from the columns of diagonals, where only the first several rows will be used (typically) for off-diagonals. |
| <code>symmetric</code>   | logical; if true the result will be symmetric (inheriting from class <code>symmetricMatrix</code> ) and only the upper or lower triangle must be specified (via <code>k</code> and <code>diagonals</code> ).   |
| <code>repr</code>        | character string, one of "C", "T", or "R", specifying the sparse representation to be used for the result, i.e., one from the super classes <code>CsparseMatrix</code> , <code>TsparseMatrix</code> , or <code>RsparseMatrix</code> .  |
| <code>giveCsparse</code> | <b>(deprecated, replaced with repr):</b> logical indicating if the result should be a <code>CsparseMatrix</code> or a <code>TsparseMatrix</code> , where the default was <code>TRUE</code> , and now is determined from <code>repr</code> ; very often <code>Csparse</code> matrices are more efficient subsequently, but not always.  |

**Value**

a sparse matrix (of class `CsparseMatrix`) of dimension  $n \times m$  with diagonal “bands” as specified.

**See Also**

`band`, for extraction of matrix bands; `bdiag`, `diag`, `sparseMatrix`, `Matrix`.

## Examples

```

diags <- list(1:30, 10*(1:20), 100*(1:20))
s1 <- bandSparse(13, k = -c(0:2, 6), diag = c(diags, diags[2]), symm=TRUE)
s1
s2 <- bandSparse(13, k = c(0:2, 6), diag = c(diags, diags[2]), symm=TRUE)
stopifnot(identical(s1, t(s2)), is(s1,"dsCMatrix"))

## a pattern Matrix of *full* (sub-)diagonals:
bk <- c(0:4, 7,9)
(s3 <- bandSparse(30, k = bk, symm = TRUE))

## If you want a pattern matrix, but with "sparse"-diagonals,
## you currently need to go via logical sparse:
lLis <- lapply(list(rpois(20, 2), rpois(20, 1), rpois(20, 3))[c(1:3, 2:3, 3:2)],
              as.logical)
(s4 <- bandSparse(20, k = bk, symm = TRUE, diag = lLis))
(s4. <- as(drop0(s4), "nsparseMatrix"))

n <- 1e4
bk <- c(0:5, 7,11)
bMat <- matrix(1:8, n, 8, byrow=TRUE)
bLis <- as.data.frame(bMat)
B <- bandSparse(n, k = bk, diag = bLis)
Bs <- bandSparse(n, k = bk, diag = bLis, symmetric=TRUE)
B[1:15, 1:30]
Bs[1:15, 1:30]
## can use a list *or* a matrix for specifying the diagonals:
stopifnot(identical(B, bandSparse(n, k = bk, diag = bMat)),
          identical(Bs, bandSparse(n, k = bk, diag = bMat, symmetric=TRUE))
          , inherits(B, "dtCMatrix") # triangular!
)

```

---

bdiag

---

*Construct a Block Diagonal Matrix*

---

## Description

Build a block diagonal matrix given several building block matrices.

## Usage

```

bdiag(...)
.bdiag(lst)

```

## Arguments

... individual matrices or a [list](#) of matrices.  
 lst non-empty [list](#) of matrices.

## Details

For non-trivial argument list, `bdiag()` calls `.bdiag()`. The latter maybe useful to programmers.

**Value**

A *sparse* matrix obtained by combining the arguments into a block diagonal matrix.

The value of `bdiag()` inherits from class `CsparseMatrix`, whereas `.bdiag()` returns a `TsparseMatrix`.

**Note**

This function has been written and is efficient for the case of relatively few block matrices which are typically sparse themselves.

It is currently *inefficient* for the case of many small dense block matrices. For the case of *many* dense  $k \times k$  matrices, the `bdiag_m()` function in the ‘Examples’ is an order of magnitude faster.

**Author(s)**

Martin Maechler, built on a version posted by Berton Gunter to R-help; earlier versions have been posted by other authors, notably Scott Chasalow to S-news. Doug Bates’s faster implementation builds on `TsparseMatrix` objects.

**See Also**

`Diagonal` for constructing matrices of class `diagonalMatrix`, or `kronecker` which also works for "Matrix" inheriting matrices.

`bandSparse` constructs a *banded* sparse matrix from its non-zero sub-/super - diagonals.

Note that other CRAN R packages have own versions of `bdiag()` which return traditional matrices.

**Examples**

```
bdiag(matrix(1:4, 2), diag(3))
## combine "Matrix" class and traditional matrices:
bdiag(Diagonal(2), matrix(1:3, 3,4), diag(3:2))

m1st <- list(1, 2:3, diag(x=5:3), 27, cbind(1,3:6), 100:101)
bdiag(m1st)
stopifnot(identical(bdiag(m1st),
                    bdiag(lapply(m1st, as.matrix))))

m1 <- c(as(matrix((1:24)%% 11 == 0, 6,4),"nMatrix"),
        rep(list(Diagonal(2, x=TRUE)), 3))
m1n <- c(m1, Diagonal(x = 1:3))
stopifnot(is(bdiag(m1), "lsparseMatrix"),
          is(bdiag(m1n), "dsparseMatrix" )

## random (diagonal-)block-triangular matrices:
rblockTri <- function(nb, max.ni, lambda = 3) {
  .bdiag(replicate(nb, {
    n <- sample.int(max.ni, 1)
    tril(Matrix(rpois(n * n, lambda = lambda), n, n)) }))
}

(T4 <- rblockTri(4, 10, lambda = 1))
image(T1 <- rblockTri(12, 20))
```

```
##' Fast version of Matrix :: .bdiag() -- for the case of *many* (k x k) matrices:
##' @param lmat list(<mat1>, <mat2>, ....., <mat_N>) where each mat_j is a k x k 'matrix'
##' @return a sparse (N*k x N*k) matrix of class \code{"\linkS4class{dgCMatrix}"}.
bdiag_m <- function(lmat) {
  ## Copyright (C) 2016 Martin Maechler, ETH Zurich
  if(!length(lmat)) return(new("dgCMatrix"))
  stopifnot(is.list(lmat), is.matrix(lmat[[1]]),
            (k <- (d <- dim(lmat[[1]]))[1]) == d[2], # k x k
            all(vapply(lmat, dim, integer(2)) == k)) # all of them
  N <- length(lmat)
  if(N * k > .Machine$integer.max)
    stop("resulting matrix too large; would be M x M, with M=", N*k)
  M <- as.integer(N * k)
  ## result: an M x M matrix
  new("dgCMatrix", Dim = c(M,M),
      ## 'i :' maybe there's a faster way (w/o matrix indexing), but elegant?
      i = as.vector(matrix(0L:(M-1L), nrow=k)[, rep(seq_len(N), each=k)]),
      p = k * 0L:M,
      x = as.double(unlist(lmat, recursive=FALSE, use.names=FALSE)))
}

l12 <- replicate(12, matrix(rpois(16, lambda = 6.4), 4, 4),
                    simplify=FALSE)
dim(T12 <- bdiag_m(l12))# 48 x 48
T12[1:20, 1:20]
```

boolmatmult-methods

*Boolean Arithmetic Matrix Products: %&% and Methods*

---

## Description

For boolean or “pattern” matrices, i.e., R objects of class `nMatrix`, it is natural to allow matrix products using boolean instead of numerical arithmetic.

In package **Matrix**, we use the binary operator `%&%` (aka “infix”) function) for this and provide methods for all our matrices and the traditional R matrices (see [matrix](#)).

## Value

a pattern matrix, i.e., inheriting from `nMatrix`, or an `ldiMatrix` in case of a diagonal matrix.

## Methods

We provide methods for both the “traditional” (R base) matrices and numeric vectors and conceptually all matrices and `sparseVectors` in package **Matrix**.

```
signature(x = "ANY", y = "ANY")
signature(x = "ANY", y = "Matrix")
signature(x = "Matrix", y = "ANY")
signature(x = "nMatrix", y = "nMatrix")
signature(x = "nMatrix", y = "nsparseMatrix")
```

```
signature(x = "nsparseMatrix", y = "nMatrix")
signature(x = "nsparseMatrix", y = "nsparseMatrix")
signature(x = "sparseVector", y = "sparseVector")
```

### Note

These boolean arithmetic matrix products had been newly introduced for **Matrix** 1.2.0 (March 2015). Its implementation has still not been tested extensively.

Originally, it was left unspecified how non-structural zeros, i.e., 0's as part of the  $M @ x$  slot should be treated for numeric ("**dMatrix**") and logical ("**lMatrix**") sparse matrices. We now specify that boolean matrix products should behave as if applied to `drop0(M)`, i.e., as if dropping such zeros from the matrix before using it.

Equivalently, for all matrices  $M$ , boolean arithmetic should work as if applied to  $M \neq 0$  (or  $M \neq \text{FALSE}$ ).

The current implementation ends up coercing both  $x$  and  $y$  to (virtual) class `nsparseMatrix` which may be quite inefficient for dense matrices. A future implementation may well return a matrix with **different** class, but the "same" content, i.e., the same matrix entries  $m_{ij}$ .

### See Also

`%*%`, `crossprod()`, or `tcrossprod()`, for (regular) matrix product methods.

### Examples

```
set.seed(7)
L <- Matrix(rnorm(20) > 1,      4,5)
(N <- as(L, "nMatrix"))
L. <- L; L.[1:2,1] <- TRUE; L.@x[1:2] <- FALSE; L. # has "zeros" to drop0()
D <- Matrix(round(rnorm(30)), 5,6) # -> values in -1:1 (for this seed)
L %%% D
stopifnot(identical(L %%% D, N %%% D),
           all(L %%% D == as((L %*% abs(D)) > 0, "sparseMatrix")))

## cross products , possibly with boolArith = TRUE :
crossprod(N)      # -> sparse patter'n' (TRUE/FALSE : boolean arithmetic)
crossprod(N + 0)  # -> numeric Matrix (with same "pattern")
stopifnot(all(crossprod(N) == t(N) %%% N),
           identical(crossprod(N), crossprod(N + 0, boolArith=TRUE)),
           identical(crossprod(L), crossprod(N, boolArith=FALSE)))
crossprod(D, boolArith = TRUE) # pattern: "nsCMatrix"
crossprod(L, boolArith = TRUE) # ditto
crossprod(L, boolArith = FALSE) # numeric: "dsCMatrix"
```

## Description

Classes `BunchKaufman` and `pBunchKaufman` represent Bunch-Kaufman factorizations of  $n \times n$  real, symmetric matrices  $A$ , having the general form

$$A = UD_UU' = LD_LL'$$

where  $D_U$  and  $D_L$  are symmetric, block diagonal matrices composed of  $b_U$  and  $b_L$   $1 \times 1$  or  $2 \times 2$  diagonal blocks;  $U = \prod_{k=1}^{b_U} P_k U_k$  is the product of  $b_U$  row-permuted unit upper triangular matrices, each having nonzero entries above the diagonal in 1 or 2 columns; and  $L = \prod_{k=1}^{b_L} P_k L_k$  is the product of  $b_L$  row-permuted unit lower triangular matrices, each having nonzero entries below the diagonal in 1 or 2 columns.

These classes store the nonzero entries of the  $2b_U + 1$  or  $2b_L + 1$  factors, which are individually sparse, in a dense format as a vector of length  $nn$  (`BunchKaufman`) or  $n(n+1)/2$  (`pBunchKaufman`), the latter giving the “packed” representation.

## Slots

`Dim, Dimnames` inherited from virtual class `MatrixFactorization`.

`uplo` a string, either “U” or “L”, indicating which triangle (upper or lower) of the factorized symmetric matrix was used to compute the factorization and in turn how the `x` slot is partitioned.

`x` a numeric vector of length  $n*n$  (`BunchKaufman`) or  $n*(n+1)/2$  (`pBunchKaufman`), where  $n = \text{Dim}[1]$ . The details of the representation are specified by the manual for LAPACK routines `dsytrf` and `dsptf`.

`perm` an integer vector of length  $n = \text{Dim}[1]$  specifying row and column interchanges as described in the manual for LAPACK routines `dsytrf` and `dsptf`.

## Extends

Class `BunchKaufmanFactorization`, directly. Class `MatrixFactorization`, by class `BunchKaufmanFactorization`, distance 2.

## Instantiation

Objects can be generated directly by calls of the form `new("BunchKaufman", ...)` or `new("pBunchKaufman", ...)`, but they are more typically obtained as the value of `BunchKaufman(x)` for `x` inheriting from `dsyMatrix` or `dspMatrix`.

## Methods

`coerce signature(from = "BunchKaufman", to = "dtrMatrix")`: returns a `dtrMatrix`, useful for inspecting the internal representation of the factorization; see ‘Note’.

`coerce signature(from = "pBunchKaufman", to = "dtpMatrix")`: returns a `dtpMatrix`, useful for inspecting the internal representation of the factorization; see ‘Note’.

`determinant signature(from = "p?BunchKaufman", logarithm = "logical")`: computes the determinant of the factorized matrix  $A$  or its logarithm.

`expand1 signature(x = "p?BunchKaufman")`: see [expand1-methods](#).

`expand2 signature(x = "p?BunchKaufman")`: see [expand2-methods](#).

`solve signature(a = "p?BunchKaufman", b = .)`: see [solve-methods](#).

## Note

In **Matrix** < 1.6-0, class `BunchKaufman` extended `dtrMatrix` and class `pBunchKaufman` extended `dtpMatrix`, reflecting the fact that the internal representation of the factorization is fundamentally triangular: there are  $n(n+1)/2$  “parameters”, and these can be arranged systematically to form an  $n \times n$  triangular matrix. **Matrix** 1.6-0 removed these extensions so that methods would no longer be inherited from `dtrMatrix` and `dtpMatrix`. The availability of such methods gave the wrong impression that `BunchKaufman` and `pBunchKaufman` represent a (singular) matrix, when in fact they represent an ordered set of matrix factors.

The coercions `as(., "dtrMatrix")` and `as(., "dtpMatrix")` are provided for users who understand the caveats.

BunchKaufman-methods

*Methods for Bunch-Kaufman Factorization*

---

## Description

Computes the Bunch-Kaufman factorization of an  $n \times n$  real, symmetric matrix  $A$ , which has the general form

$$A = UD_UU' = LD_LL'$$

where  $D_U$  and  $D_L$  are symmetric, block diagonal matrices composed of  $b_U$  and  $b_L$   $1 \times 1$  or  $2 \times 2$  diagonal blocks;  $U = \prod_{k=1}^{b_U} P_k U_k$  is the product of  $b_U$  row-permuted unit upper triangular matrices, each having nonzero entries above the diagonal in 1 or 2 columns; and  $L = \prod_{k=1}^{b_L} P_k L_k$  is the product of  $b_L$  row-permuted unit lower triangular matrices, each having nonzero entries below the diagonal in 1 or 2 columns.

Methods are built on LAPACK routines `dsytrf` and `dsptrf`.

## Usage

```

BunchKaufman(x, ...)
## S4 method for signature 'dsyMatrix'
BunchKaufman(x, warnSing = TRUE, ...)
## S4 method for signature 'dspMatrix'
BunchKaufman(x, warnSing = TRUE, ...)
## S4 method for signature 'matrix'
BunchKaufman(x, uplo = "U", ...)

```

## Arguments

|                       |   |
|-----------------------|---|
| <code>x</code>        | a <a href="#">finite</a> symmetric matrix or <a href="#">Matrix</a> to be factorized. If <code>x</code> is square but not symmetric, then it will be <i>treated</i> as symmetric; see <code>uplo</code> . |
| <code>warnSing</code> | a logical indicating if a <a href="#">warning</a> should be signaled for singular <code>x</code> .  |
| <code>uplo</code>     | a string, either "U" or "L", indicating which triangle of <code>x</code> should be used to compute the factorization.   |
| <code>...</code>      | further arguments passed to or from methods.  |

## Value

An object representing the factorization, inheriting from virtual class [BunchKaufmanFactorization](#). The specific class is [BunchKaufman](#) unless `x` inherits from virtual class [packedMatrix](#), in which case it is [pBunchKaufman](#).

## References

The LAPACK source code, including documentation; see <https://netlib.org/lapack/double/dsytrf.f> and <https://netlib.org/lapack/double/dsptrf.f>.

Generic functions [expand1](#) and [expand2](#), for constructing matrix factors from the result.

Generic functions [Cholesky](#), [Schur](#), [lu](#), and [qr](#), for computing other factorizations.

## Examples

```
showMethods("BunchKaufman", inherited = FALSE)
set.seed(0)

data(CAex, package = "Matrix")
class(CAex) # dgCMatrix
isSymmetric(CAex) # symmetric, but not formally

A <- as(CAex, "symmetricMatrix")
class(A) # dsCMatrix

## Have methods for denseMatrix (unpacked and packed),
## but not yet sparseMatrix ...
## Not run:
(bk.A <- BunchKaufman(A))

## End(Not run)
(bk.A <- BunchKaufman(as(A, "unpackedMatrix"))

## A ~ U D U' in floating point
str(e.bk.A <- expand2(bk.A), max.level = 2L)
stopifnot(all.equal(as(A, "matrix"), as(Reduce(`*`, e.bk.A), "matrix")))
```

---

CAex

---

*Albers' example Matrix with "Difficult" Eigen Factorization*

---

## Description

An example of a sparse matrix for which [eigen\(\)](#) seemed to be difficult, an unscaled version of this has been posted to the web, accompanying an E-mail to R-help (<https://stat.ethz.ch/mailman/listinfo/r-help>), by Casper J Albers, Open University, UK.

## Usage

```
data(CAex)
```

## Format

This is a  $72 \times 72$  symmetric matrix with 216 non-zero entries in five bands, stored as sparse matrix of class `dgCMatrix`.

## Details

Historical note (2006-03-30): In earlier versions of R, `eigen(CAex)` fell into an infinite loop whereas `eigen(CAex, EISPACK=TRUE)` had been okay.

## Examples

```
data(CAex, package = "Matrix")
str(CAex) # of class "dgCMatrix"

image(CAex) # -> it's a simple band matrix with 5 bands
## and the eigen values are basically 1 (42 times) and 0 (30 x):
zapsmall(ev <- eigen(CAex, only.values=TRUE)$values)
## i.e., the matrix is symmetric, hence
sCA <- as(CAex, "symmetricMatrix")
## and
stopifnot(class(sCA) == "dsCMatrix",
           as(sCA, "matrix") == as(CAex, "matrix"))
```

---

|                |   |
|----------------|---|
| cbind2-methods | ' <i>cbind()</i> ' and ' <i>rbind()</i> ' recursively built on <i>cbind2/rbind2</i> |
|----------------|---|

---

## Description

The base functions `cbind` and `rbind` are defined for an arbitrary number of arguments and hence have the first formal argument `...`. Now, when S4 objects are found among the arguments, base `cbind()` and `rbind()` internally “dispatch” *recursively*, calling `cbind2` or `rbind2` respectively, where these have methods defined and so should dispatch appropriately.

`cbind2()` and `rbind2()` are from the **methods** package, i.e., standard R, and have been provided for binding together *two* matrices, where in **Matrix**, we have defined methods for these and the 'Matrix' matrices.

## Usage

```
## cbind(..., deparse.level = 1)
## rbind(..., deparse.level = 1)

## S4 method for signature 'Matrix,Matrix'
cbind2(x, y, ...)
## S4 method for signature 'Matrix,Matrix'
rbind2(x, y, ...)
```

## Arguments

`...` for `[cr]bind`, vector- or matrix-like R objects to be bound together; for `[cr]bind2`, further arguments passed to or from methods; see `cbind` and `cbind2`.

`deparse.level` integer controlling the construction of labels in the case of non-matrix-like arguments; see `cbind`.

`x, y` vector- or matrix-like R objects to be bound together.

### Value

typically a ‘matrix-like’ object of a similar `class` as the first argument in . . .

Note that sometimes by default, the result is a `sparseMatrix` if one of the arguments is (even in the case where this is not efficient). In other cases, the result is chosen to be sparse when there are more zero entries than non-zero ones (as the default `sparse` in `Matrix()`).

### Author(s)

Martin Maechler

### See Also

`cbind`, `cbind2`.

Our class definition help pages mentioning `cbind2()` and `rbind2()` methods: `"denseMatrix"`, `"diagonalMatrix"`, `"indMatrix"`.

### Examples

```
(a <- matrix(c(2:1,1:2), 2,2))

(M1 <- cbind(0, rbind(a, 7))) # a traditional matrix

D <- Diagonal(2)
(M2 <- cbind(4, a, D, -1, D, 0)) # a sparse Matrix

stopifnot(validObject(M2), inherits(M2, "sparseMatrix"),
           dim(M2) == c(2,9))
```

### Description

`CHMfactor` is the virtual class of sparse Cholesky factorizations of  $n \times n$  real, symmetric matrices  $A$ , having the general form

$$P_1 A P_1' = L_1 D L_1' \stackrel{D_{jj} \geq 0}{=} L L'$$

or (equivalently)

$$A = P_1' L_1 D L_1' P_1 \stackrel{D_{jj} \geq 0}{=} P_1' L L' P_1$$

where  $P_1$  is a permutation matrix,  $L_1$  is a unit lower triangular matrix,  $D$  is a diagonal matrix, and  $L = L_1 \sqrt{D}$ . The second equalities hold only for positive semidefinite  $A$ , for which the diagonal entries of  $D$  are non-negative and  $\sqrt{D}$  is well-defined.

The implementation of class `CHMfactor` is based on `CHOLMOD`'s C-level `cholmod_factor_struct`. Virtual subclasses `CHMsimpl` and `CHMsuper` separate the simplicial and supernodal variants. These have nonvirtual subclasses `[dn]CHMsimpl` and `[dn]CHMsuper`, where prefix ‘d’ and prefix ‘n’ are reserved for numeric and symbolic factorizations, respectively.

**Usage**

```
isLDL(x)
```

**Arguments**

**x** an object inheriting from virtual class `CHMfactor`, almost always the result of a call to generic function `Cholesky`.

**Value**

`isLDL(x)` returns TRUE or FALSE: TRUE if `x` stores the lower triangular entries of  $L_1 - I + D$ , FALSE if `x` stores the lower triangular entries of  $L$ .

**Slots**

Of `CHMfactor`:

`Dim, Dimnames` inherited from virtual class `MatrixFactorization`.

`colcount` an integer vector of length `Dim[1]` giving an *estimate* of the number of nonzero entries in each column of the lower triangular Cholesky factor. If symbolic analysis was performed prior to factorization, then the estimate is exact.

`perm` a 0-based integer vector of length `Dim[1]` specifying the permutation applied to the rows and columns of the factorized matrix. `perm` of length 0 is valid and equivalent to the identity permutation, implying no pivoting.

`type` an integer vector of length 6 specifying details of the factorization. The elements correspond to members `ordering`, `is_ll`, `is_super`, `is_monotonic`, `maxcsize`, and `maxesize` of the original `cholmod_factor_struct`. Simplicial and supernodal factorizations are distinguished by `is_super`. Simplicial factorizations do not use `maxcsize` or `maxesize`. Supernodal factorizations do not use `is_ll` or `is_monotonic`.

Of `CHMsimpl` (all unused by `nCHMsimpl`):

`nz` an integer vector of length `Dim[1]` giving the number of nonzero entries in each column of the lower triangular Cholesky factor. There is at least one nonzero entry in each column, because the diagonal elements of the factor are stored explicitly.

`p` an integer vector of length `Dim[1]+1`. Row indices of nonzero entries in column `j` of the lower triangular Cholesky factor are obtained as `i[p[j]+seq_len(nz[j]))+1]`.

`i` an integer vector of length greater than or equal to `sum(nz)` containing the row indices of nonzero entries in the lower triangular Cholesky factor. These are grouped by column and sorted within columns, but the columns themselves need not be ordered monotonically. Columns may be overallocated, i.e., the number of elements of `i` reserved for column `j` may exceed `nz[j]`.

`prv, nxt` integer vectors of length `Dim[1]+2` indicating the order in which the columns of the lower triangular Cholesky factor are stored in `i` and `x`. Starting from `j <- Dim[1]+2`, the recursion `j <- nxt[j+1]+1` traverses the columns in forward order and terminates when `nxt[j+1] = -1`. Starting from `j <- Dim[1]+1`, the recursion `j <- prv[j+1]+1` traverses the columns in backward order and terminates when `prv[j+1] = -1`.

Of `dCHMsimpl`:

`x` a numeric vector parallel to `i` containing the corresponding nonzero entries of the lower triangular Cholesky factor  $L$  or (if and only if `type[2]` is 0) of the lower triangular matrix  $L_1 - I + D$ .

Of CHMsuper:

`super`, `pi`, `px` integer vectors of length `nsuper+1`, where `nsuper` is the number of supernodes. `super[j]+1` is the index of the leftmost column of supernode `j`. The row indices of supernode `j` are obtained as `s[pi[j]+seq_len(pi[j+1]-pi[j])]+1`. The numeric entries of supernode `j` are obtained as `x[px[j]+seq_len(px[j+1]-px[j])]+1` (if slot `x` is available).

`s` an integer vector of length greater than or equal to `Dim[1]` containing the row indices of the supernodes. `s` may contain duplicates, but not within a supernode, where the row indices must be increasing.

Of dCHMsuper:

`x` a numeric vector of length less than or equal to `prod(Dim)` containing the numeric entries of the supernodes.

## Extends

Class [MatrixFactorization](#), directly.

## Instantiation

Objects can be generated directly by calls of the form `new("dCHMsimpl", ...)`, etc., but `dCHMsimpl` and `dCHMsuper` are more typically obtained as the value of [Cholesky](#)(`x`, ...) for `x` inheriting from [sparseMatrix](#) (often [dsCMatrix](#)).

There is currently no API outside of calls to [new](#) for generating `nCHMsimpl` and `nCHMsuper`. These classes are vestigial and may be formally deprecated in a future version of **Matrix**.

## Methods

`coerce signature(from = "CHMsimpl", to = "dtCMatrix")`: returns a [dtCMatrix](#) representing the lower triangular Cholesky factor  $L$  or the lower triangular matrix  $L_1 - I + D$ , the latter if and only if `from@type[2]` is 0.

`coerce signature(from = "CHMsuper", to = "dgCMatrix")`: returns a [dgCMatrix](#) representing the lower triangular Cholesky factor  $L$ . Note that, for supernodes spanning two or more columns, the supernodal algorithm by design stores non-structural zeros above the main diagonal, hence [dgCMatrix](#) is indeed more appropriate than [dtCMatrix](#) as a coercion target.

`determinant signature(from = "CHMfactor", logarithm = "logical")`: behaves according to an optional argument `sqrt`. If `sqrt = FALSE`, then this method computes the determinant of the factorized matrix  $A$  or its logarithm. If `sqrt = TRUE`, then this method computes the determinant of the factor  $L = L_1 \text{sqrt}(D)$  or its logarithm, giving NaN for the modulus when  $D$  has negative diagonal elements. For backwards compatibility, the default value of `sqrt` is TRUE, but that can be expected change in a future version of **Matrix**, hence defensive code will always set `sqrt` (to TRUE, if the code must remain backwards compatible with **Matrix** < 1.6-0). Calls to this method not setting `sqrt` may warn about the pending change. The warnings can be disabled with [options](#)(`Matrix.warnSqrtDefault` = 0).

`diag signature(x = "CHMfactor")`: returns a numeric vector of length  $n$  containing the diagonal elements of  $D$ , which (if they are all non-negative) are the squared diagonal elements of  $L$ .

`expand signature(x = "CHMfactor")`: see [expand-methods](#).

```

expand1 signature(x = "CHMsimpl"): see expand1-methods.
expand1 signature(x = "CHMsuper"): see expand1-methods.
expand2 signature(x = "CHMsimpl"): see expand2-methods.
expand2 signature(x = "CHMsuper"): see expand2-methods.
image signature(x = "CHMfactor"): see image-methods.
nnzero signature(x = "CHMfactor"): see nnzero-methods.
solve signature(a = "CHMfactor", b = .): see solve-methods.
update signature(object = "CHMfactor"): returns a copy of object with the same
  nonzero pattern but with numeric entries updated according to additional arguments parent
  and mult, where parent is (coercible to) a dsCMatrix or a dgCMatrix and mult is a
  numeric vector of positive length.
  The numeric entries are updated with those of the Cholesky factor of  $F(\text{parent}) +$ 
   $\text{mult}[1] * I$ , i.e.,  $F(\text{parent})$  plus  $\text{mult}[1]$  times the identity matrix, where  $F =$ 
  identity for symmetric parent and  $F = \text{tcrossprod}$  for other parent. The nonzero
  pattern of  $F(\text{parent})$  must match that of  $S$  if  $\text{object} = \text{Cholesky}(S, \dots)$ .
updown signature(update = ., C = ., object = "CHMfactor"): see
  updown-methods.

```

chol-methods

*Compute the Cholesky Factor of a Matrix***Description**

Computes the upper triangular Cholesky factor of an  $n \times n$  real, symmetric, positive semidefinite matrix  $A$ , optionally after pivoting. That is the factor  $L'$  in

$$P_1 A P_1' = L L'$$

or (equivalently)

$$A = P_1' L L' P_1$$

where  $P_1$  is a permutation matrix.

Methods for [denseMatrix](#) are built on LAPACK routines `dpstrf`, `dpotrf`, and `dpptrf`. The latter two do not permute rows or columns, so that  $P_1$  is an identity matrix.

Methods for [sparseMatrix](#) are built on CHOLMOD routines `cholmod_analyze` and `cholmod_factorize_p`.

## Usage

```
chol(x, ...)
## S4 method for signature 'dsyMatrix'
chol(x, pivot = FALSE, tol = -1, ...)
## S4 method for signature 'dspMatrix'
chol(x, ...)
## S4 method for signature 'dsCMatrix'
chol(x, pivot = FALSE, ...)
## S4 method for signature 'ddiMatrix'
chol(x, ...)
## S4 method for signature 'generalMatrix'
chol(x, uplo = "U", ...)
## S4 method for signature 'triangularMatrix'
chol(x, uplo = "U", ...)
```

## Arguments

|                    |   |
|--------------------|---|
| <code>x</code>     | a <a href="#">finite</a> , symmetric, positive semidefinite matrix or <a href="#">Matrix</a> to be factorized. If <code>x</code> is square but not symmetric, then it will be <i>treated</i> as symmetric; see <code>uplo</code> . Methods for dense <code>x</code> require positive definiteness when <code>pivot = FALSE</code> . Methods for sparse (but not diagonal) <code>x</code> require positive definiteness unconditionally. |
| <code>pivot</code> | a logical indicating if the rows and columns of <code>x</code> should be pivoted. Methods for sparse <code>x</code> employ the approximate minimum degree (AMD) algorithm in order to reduce fill-in, i.e., without regard for numerical stability.   |
| <code>tol</code>   | a <a href="#">finite</a> numeric tolerance, used only if <code>pivot = TRUE</code> . The factorization algorithm stops if the pivot is less than or equal to <code>tol</code> . Negative <code>tol</code> is equivalent to <code>nrow(x) * .Machine\$double.eps * max(diag(x))</code> .   |
| <code>uplo</code>  | a string, either "U" or "L", indicating which triangle of <code>x</code> should be used to compute the factorization. The default is "U", even for lower triangular <code>x</code> , to be consistent with <a href="#">chol</a> from <b>base</b> .  |
| <code>...</code>   | further arguments passed to or from methods.  |

## Details

For `x` inheriting from [diagonalMatrix](#), the diagonal result is computed directly and without pivoting, i.e., bypassing CHOLMOD.

For all other `x`, `chol(x, pivot = value)` calls [Cholesky](#)(`x`, `perm = value`, ...) under the hood. If you must know the permutation  $P_1$  in addition to the Cholesky factor  $L'$ , then call [Cholesky](#) directly, as the result of `chol(x, pivot = TRUE)` specifies  $L'$  but not  $P_1$ .

## Value

A matrix, [triangularMatrix](#), or [diagonalMatrix](#) representing the upper triangular Cholesky factor  $L'$ . The result is a traditional matrix if `x` is a traditional matrix, dense if `x` is dense, and sparse if `x` is sparse.

---

chol2inv-methods      *Inverse from Cholesky Factor*

---

## Description

Given *formally* upper and lower triangular matrices  $U$  and  $L$ , compute  $(U'U)^{-1}$  and  $(LL')^{-1}$ , respectively.

This function can be seen as way to compute the inverse of a symmetric positive definite matrix given its Cholesky factor. Equivalently, it can be seen as a way to compute  $(X'X)^{-1}$  given the  $R$  part of the QR factorization of  $X$ , if  $R$  is constrained to have positive diagonal entries.

### Usage

```
chol2inv(x, ...)
## S4 method for signature 'dtrMatrix'
chol2inv(x, ...)
## S4 method for signature 'dtCMatrix'
chol2inv(x, ...)
## S4 method for signature 'generalMatrix'
chol2inv(x, uplo = "U", ...)
```

### Arguments

|                   |   |
|-------------------|---|
| <code>x</code>    | a square matrix or <a href="#">Matrix</a> , typically the result of a call to <a href="#">chol</a> . If <code>x</code> is square but not (formally) triangular, then only the upper or lower triangle is considered, depending on optional argument <code>uplo</code> if <code>x</code> is a <a href="#">Matrix</a> . |
| <code>uplo</code> | a string, either "U" or "L", indicating which triangle of <code>x</code> contains the Cholesky factor. The default is "U", to be consistent with <a href="#">chol2inv</a> from <b>base</b> .  |
| <code>...</code>  | further arguments passed to or from methods.  |

### Value

A matrix, [symmetricMatrix](#), or [diagonalMatrix](#) representing the inverse of the positive definite matrix whose Cholesky factor is `x`. The result is a traditional matrix if `x` is a traditional matrix, dense if `x` is dense, and sparse if `x` is sparse.

### See Also

The default method from **base**, [chol2inv](#), called for traditional matrices `x`.

Generic function [chol](#), for computing the upper triangular Cholesky factor  $L'$  of a symmetric positive semidefinite matrix.

Generic function [solve](#), for solving linear systems and (as a corollary) for computing inverses more generally.

### Examples

```
(A <- Matrix(cbind(c(1, 1, 1), c(1, 2, 4), c(1, 4, 16))))
(R <- chol(A))
(L <- t(R))
(R2i <- chol2inv(R))
(L2i <- chol2inv(R))
stopifnot(exprs = {
  all.equal(R2i, tcrossprod(solve(R)))
  all.equal(L2i, crossprod(solve(L)))
  all.equal(as(R2i %**% A, "matrix"), diag(3L)) # the identity
  all.equal(as(L2i %**% A, "matrix"), diag(3L)) # ditto
})
```

Cholesky-class

*Dense Cholesky Factorizations***Description**

Classes `Cholesky` and `pCholesky` represent dense, pivoted Cholesky factorizations of  $n \times n$  real, symmetric, positive semidefinite matrices  $A$ , having the general form

$$P_1 A P_1' = L_1 D L_1' = L L'$$

or (equivalently)

$$A = P_1' L_1 D L_1' P_1 = P_1' L L' P_1$$

where  $P_1$  is a permutation matrix,  $L_1$  is a unit lower triangular matrix,  $D$  is a non-negative diagonal matrix, and  $L = L_1 \sqrt{D}$ .

These classes store the entries of the Cholesky factor  $L$  or its transpose  $L'$  in a dense format as a vector of length  $nn$  (`Cholesky`) or  $n(n+1)/2$  (`pCholesky`), the latter giving the “packed” representation.

**Slots**

`Dim`, `Dimnames` inherited from virtual class `MatrixFactorization`.

`uplo` a string, either "U" or "L", indicating which triangle (upper or lower) of the factorized symmetric matrix was used to compute the factorization and in turn whether `x` stores  $L'$  or  $L$ .

`x` a numeric vector of length  $n*n$  (`Cholesky`) or  $n*(n+1)/2$  (`pCholesky`), where  $n=Dim[1]$ , listing the entries of the Cholesky factor  $L$  or its transpose  $L'$  in column-major order.

`perm` a 1-based integer vector of length `Dim[1]` specifying the permutation applied to the rows and columns of the factorized matrix. `perm` of length 0 is valid and equivalent to the identity permutation, implying no pivoting.

**Extends**

Class `CholeskyFactorization`, directly. Class `MatrixFactorization`, by class `CholeskyFactorization`, distance 2.

**Instantiation**

Objects can be generated directly by calls of the form `new("Cholesky", ...)` or `new("pCholesky", ...)`, but they are more typically obtained as the value of `Cholesky(x)` for `x` inheriting from `dsyMatrix` or `dspMatrix` (often the subclasses of those reserved for positive semidefinite matrices, namely `dpoMatrix` and `dppMatrix`).

**Methods**

`coerce signature(from = "Cholesky", to = "dtrMatrix")`: returns a `dtrMatrix` representing the Cholesky factor  $L$  or its transpose  $L'$ ; see ‘Note’.

`coerce signature(from = "pCholesky", to = "dtpMatrix")`: returns a `dtpMatrix` representing the Cholesky factor  $L$  or its transpose  $L'$ ; see ‘Note’.

`determinant signature(from = "p?Cholesky", logarithm = "logical")`: computes the determinant of the factorized matrix  $A$  or its logarithm.

`diag` signature (`x = "p?Cholesky"`): returns a numeric vector of length  $n$  containing the diagonal elements of  $D$ , which are the squared diagonal elements of  $L$ .

`expand1` signature (`x = "p?Cholesky"`): see [expand1-methods](#).

`expand2` signature (`x = "p?Cholesky"`): see [expand2-methods](#).

`solve` signature (`a = "p?Cholesky", b = .`): see [solve-methods](#).

### Note

In **Matrix** < 1.6-0, class `Cholesky` extended `dtrMatrix` and class `pCholesky` extended `dtpMatrix`, reflecting the fact that the factor  $L$  is indeed a triangular matrix. **Matrix** 1.6-0 removed these extensions so that methods would no longer be inherited from `dtrMatrix` and `dtpMatrix`. The availability of such methods gave the wrong impression that `Cholesky` and `pCholesky` represent a (singular) matrix, when in fact they represent an ordered set of matrix factors.

The coercions `as(., "dtrMatrix")` and `as(., "dtpMatrix")` are provided for users who understand the caveats.

```

---

Cholesky-methods      *Methods for Cholesky Factorization*

---

## Description

Computes the pivoted Cholesky factorization of an  $n \times n$  real, symmetric matrix  $A$ , which has the general form

$$P_1 A P_1' = L_1 D L_1' \stackrel{D_{jj} \geq 0}{=} L L'$$

or (equivalently)

$$A = P_1' L_1 D L_1' P_1 \stackrel{D_{jj} \geq 0}{=} P_1' L L' P_1$$

where  $P_1$  is a permutation matrix,  $L_1$  is a unit lower triangular matrix,  $D$  is a diagonal matrix, and  $L = L_1 \sqrt{D}$ . The second equalities hold only for positive semidefinite  $A$ , for which the diagonal entries of  $D$  are non-negative and  $\sqrt{D}$  is well-defined.

Methods for [denseMatrix](#) are built on LAPACK routines `dpstrf`, `dpotrf`, and `dpptrf`. The latter two do not permute rows or columns, so that  $P_1$  is an identity matrix.

Methods for [sparseMatrix](#) are built on CHOLMOD routines `cholmod_analyze` and `cholmod_factorize_p`.

**Usage**

```

Cholesky(A, ...)
## S4 method for signature 'dsyMatrix'
Cholesky(A, perm = TRUE, tol = -1, ...)
## S4 method for signature 'dspMatrix'
Cholesky(A, ...)
## S4 method for signature 'dsCMatrix'
Cholesky(A, perm = TRUE, LDL = !super, super = FALSE,
        Imult = 0, ...)
## S4 method for signature 'ddiMatrix'
Cholesky(A, ...)
## S4 method for signature 'generalMatrix'
Cholesky(A, uplo = "U", ...)
## S4 method for signature 'triangularMatrix'
Cholesky(A, uplo = "U", ...)
## S4 method for signature 'matrix'
Cholesky(A, uplo = "U", ...)

```

**Arguments**

|                    |  |
|--------------------|--|
| <code>A</code>     | a <a href="#">finite</a> , symmetric matrix or <a href="#">Matrix</a> to be factorized. If <code>A</code> is square but not symmetric, then it will be <i>treated</i> as symmetric; see <code>uplo</code> . Methods for dense <code>A</code> require positive definiteness when <code>perm = FALSE</code> and positive semidefiniteness when <code>perm = TRUE</code> . Methods for sparse <code>A</code> require positive definiteness when <code>LDL = TRUE</code> and nonzero leading principal minors (after pivoting) when <code>LDL = FALSE</code> . Methods for sparse, <i>diagonal</i> <code>A</code> are an exception, requiring positive semidefiniteness unconditionally. |
| <code>perm</code>  | a logical indicating if the rows and columns of <code>A</code> should be pivoted. Methods for sparse <code>A</code> employ the approximate minimum degree (AMD) algorithm in order to reduce fill-in, i.e., without regard for numerical stability. Pivoting for sparsity may introduce nonpositive leading principal minors, causing the factorization to fail, in which case it may be necessary to set <code>perm = FALSE</code> .  |
| <code>tol</code>   | a <a href="#">finite</a> numeric tolerance, used only if <code>perm = TRUE</code> . The factorization algorithm stops if the pivot is less than or equal to <code>tol</code> . Negative <code>tol</code> is equivalent to <code>nrow(A) * .Machine\$double.eps * max(diag(A))</code> .   |
| <code>LDL</code>   | a logical indicating if the simplicial factorization should be computed as $P_1' L_1 D L_1' P_1$ , such that the result stores the lower triangular entries of $L_1 - I + D$ . The alternative is $P_1' L L' P_1$ , such that the result stores the lower triangular entries of $L = L_1 \sqrt{D}$ . This argument is ignored if <code>super = TRUE</code> (or if <code>super = NA</code> and the supernodal algorithm is chosen), as the supernodal code does not yet support the <code>LDL = TRUE</code> variant.  |
| <code>super</code> | a logical indicating if the factorization should use the supernodal algorithm. The alternative is the simplicial algorithm. Setting <code>super = NA</code> leaves the choice to a CHOLMOD-internal heuristic.   |
| <code>Imult</code> | a <a href="#">finite</a> number. The matrix that is factorized is $A + \text{Imult} * \text{diag}(\text{nrow}(A))$ , i.e., <code>A</code> plus <code>Imult</code> times the identity matrix. This argument is useful for symmetric, indefinite <code>A</code> , as <code>Imult &gt; max(rowSums(abs(A)) - diag(abs(A)))</code> ensures that $A + \text{Imult} * \text{diag}(\text{nrow}(A))$ is diagonally dominant. (Symmetric, diagonally dominant matrices are positive definite.)  |

`uplo` a string, either "U" or "L", indicating which triangle of  $A$  should be used to compute the factorization. The default is "U", even for lower triangular  $A$ , to be consistent with `chol` from **base**.

`...` further arguments passed to or from methods.

## Details

Note that the result of a call to `Cholesky` inherits from `CholeskyFactorization` but not `Matrix`. Users who just want a matrix should consider using `chol`, whose methods are simple wrappers around `Cholesky` returning just the upper triangular Cholesky factor  $L'$ , typically as a `triangularMatrix`. However, a more principled approach would be to construct factors as needed from the `CholeskyFactorization` object, e.g., with `expand1(x, "L")`, if  $x$  is the object.

The behaviour of `Cholesky(A, perm = TRUE)` for dense  $A$  is somewhat exceptional, in that it expects *without* checking that  $A$  is positive semidefinite. By construction, if  $A$  is positive semidefinite and the exact algorithm encounters a zero pivot, then the unfactorized trailing submatrix is the zero matrix, and there is nothing left to do. Hence when the finite precision algorithm encounters a pivot less than `tol`, it signals a warning instead of an error and zeros the trailing submatrix in order to guarantee that  $P'LL'P$  is positive semidefinite even if  $A$  is not. It follows that one way to test for positive semidefiniteness of  $A$  in the event of a warning is to analyze the error

$$\frac{\|A - P'LL'P\|}{\|A\|}.$$

See the examples and LAPACK Working Note ("LAWN") 161 for details.

## Value

An object representing the factorization, inheriting from virtual class `CholeskyFactorization`. For a traditional matrix  $A$ , the specific class is `Cholesky`. For  $A$  inheriting from `unpackedMatrix`, `packedMatrix`, and `sparseMatrix`, the specific class is `Cholesky`, `pCholesky`, and `dCHMsimpl` or `dCHMsupper`, respectively.

## Version of the SuiteSparse library, which includes CHOLMOD
Mv <- Matrix.Version()
Mv[["suitesparse"]]

```

---

coerce-methods-graph

*Conversions "graph" <-> (sparse) Matrix*

---

## Description

Since 2005, package **Matrix** has supported coercions to and from class [graph](#) from package **igraph**. Since 2013, this functionality has been exposed via functions `T2graph` and `graph2T`, which, unlike methods for `as` (from, "<Class>"), support optional arguments.

## Usage

```

graph2T(from, use.weights = )
T2graph(from, need.uniq = !isUniqueT(from), edgemode = NULL)

```

## Arguments

|                          |  |
|--------------------------|--|
| <code>from</code>        | for <code>graph2T()</code> , an R object of class "graph";<br>for <code>T2graph()</code> , a sparse matrix inheriting from " <a href="#">TsparseMatrix</a> ".  |
| <code>use.weights</code> | logical indicating if weights should be used, i.e., equivalently the result will be numeric, i.e. of class <a href="#">dgTMatrix</a> ; otherwise the result will be <a href="#">ngTMatrix</a> or <a href="#">nsTMatrix</a> , the latter if the graph is undirected. The default looks if there are weights in the graph, and if any differ from 1, weights are used. |
| <code>need.uniq</code>   | a logical indicating if <code>from</code> may need to be internally "uniquified"; do not set this and hence rather use the default, unless you know what you are doing!  |
| <code>edgemode</code>    | one of <code>NULL</code> , "directed", or "undirected". The default <code>NULL</code> looks if the matrix is symmetric and assumes "undirected" in that case.  |

## Value

For `graph2T()`, a sparse matrix inheriting from "[TsparseMatrix](#)".

For `T2graph()` an R object of class "graph".

## See Also

Package **igraph**, which provides similar coercions to and from its class `igraph` via functions `graph_from_adjacency_matrix` and `as_adjacency_matrix`.

## Examples

```

if(requireNamespace("graph")) {
  n4 <- LETTERS[1:4]; dns <- list(n4,n4)
  show(a1 <- sparseMatrix(i= c(1:4), j=c(2:4,1), x = 2, dimnames=dns))
  show(g1 <- as(a1, "graph")) # directed
  unlist(graph::edgeWeights(g1)) # all '2'

  show(a2 <- sparseMatrix(i= c(1:4,4), j=c(2:4,1:2), x = TRUE, dimnames=dns))
  show(g2 <- as(a2, "graph")) # directed
  # now if you want it undirected:
  show(g3 <- T2graph(as(a2,"TsparseMatrix"), edgemode="undirected"))
  show(m3 <- as(g3,"Matrix"))
  show( graph2T(g3) ) # a "pattern Matrix" (nsTMatrix)

  a. <- sparseMatrix(i=4:1, j=1:4, dimnames=list(n4, n4), repr="T") # no 'x'
  show(a.) # "ngTMatrix"
  show(g. <- as(a., "graph"))

}

```

---

coerce-methods-SparseM

*Sparse Matrix Coercion from and to those from package **SparseM***

---

## Description

Methods for coercion from and to sparse matrices from package **SparseM** are provided here, for ease of porting functionality to the **Matrix** package, and comparing functionality of the two packages. All these work via the usual `as(., "<class>")` coercion,

```
as(from, Class)
```

## Methods

```

from = "matrix.csr", to = "dgRMatrix" ...
from = "matrix.csc", to = "dgCMatrix" ...
from = "matrix.coo", to = "dgTMatrix" ...
from = "dgRMatrix", to = "matrix.csr" ...
from = "dgCMatrix", to = "matrix.csc" ...
from = "dgTMatrix", to = "matrix.coo" ...
from = "Matrix", to = "matrix.csr" ...
from = "matrix.csr", to = "dgCMatrix" ...
from = "matrix.coo", to = "dgCMatrix" ...
from = "matrix.csr", to = "Matrix" ...
from = "matrix.csc", to = "Matrix" ...
from = "matrix.coo", to = "Matrix" ...

```

## See Also

The documentation in CRAN package **SparseM**, such as [SparseM.ontology](#), and one important class, [matrix.csr](#).

**Description**

Form row and column sums and means for objects, for `sparseMatrix` the result may optionally be sparse (`sparseVector`), too. Row or column names are kept respectively as for **base** matrices and `colSums` methods, when the result is `numeric` vector.

**Usage**

```
colSums(x, na.rm = FALSE, dims = 1L, ...)
rowSums(x, na.rm = FALSE, dims = 1L, ...)
colMeans(x, na.rm = FALSE, dims = 1L, ...)
rowMeans(x, na.rm = FALSE, dims = 1L, ...)

## S4 method for signature 'CsparseMatrix'
colSums(x, na.rm = FALSE, dims = 1L,
        sparseResult = FALSE, ...)
## S4 method for signature 'CsparseMatrix'
rowSums(x, na.rm = FALSE, dims = 1L,
        sparseResult = FALSE, ...)
## S4 method for signature 'CsparseMatrix'
colMeans(x, na.rm = FALSE, dims = 1L,
         sparseResult = FALSE, ...)
## S4 method for signature 'CsparseMatrix'
rowMeans(x, na.rm = FALSE, dims = 1L,
         sparseResult = FALSE, ...)
```

**Arguments**

|                           |  |
|---------------------------|--|
| <code>x</code>            | a Matrix, i.e., inheriting from <code>Matrix</code> .  |
| <code>na.rm</code>        | logical. Should missing values (including NaN) be omitted from the calculations?   |
| <code>dims</code>         | completely ignored by the <code>Matrix</code> methods.   |
| <code>...</code>          | potentially further arguments, for method <-> generic compatibility.   |
| <code>sparseResult</code> | logical indicating if the result should be sparse, i.e., inheriting from class <code>sparseVector</code> . Only applicable when <code>x</code> is inheriting from a <code>sparseMatrix</code> class. |

**Value**

returns a numeric vector if `sparseResult` is `FALSE` as per default. Otherwise, returns a `sparseVector`.

`dimnames(x)` are only kept (as `names(v)`) when the resulting `v` is `numeric`, since `sparseVectors` do not have names.

**See Also**

`colSums` and the `sparseVector` classes.

## Examples

```
(M <- bdiag(Diagonal(2), matrix(1:3, 3,4), diag(3:2))) # 7 x 8
colSums(M)
d <- Diagonal(10, c(0,0,10,0,2,rep(0,5)))
MM <- kronecker(d, M)
dim(MM) # 70 80
length(MM@x) # 160, but many are '0' ; drop those:
MM <- drop0(MM)
length(MM@x) # 32
cm <- colSums(MM)
(scm <- colSums(MM, sparseResult = TRUE))
stopifnot(is(scm, "sparseVector"),
           identical(cm, as.numeric(scm)))
rowSums(MM, sparseResult = TRUE) # 14 of 70 are not zero
colMeans(MM, sparseResult = TRUE) # 16 of 80 are not zero
## Since we have no 'NA's, these two are equivalent :
stopifnot(identical(rowMeans(MM, sparseResult = TRUE),
                    rowMeans(MM, sparseResult = TRUE, na.rm = TRUE)),
           rowMeans(Diagonal(16)) == 1/16,
           colSums(Diagonal(7)) == 1)

## dimnames(x) --> names( <value> ) :
dimnames(M) <- list(paste0("r", 1:7), paste0("v",1:8))
M
colSums(M)
rowMeans(M)
## Assertions :
stopifnot(exprs = {
  all.equal(colSums(M),
            structure(c(1,1,6,6,6,6,3,2), names = colnames(M)))
  all.equal(rowMeans(M),
            structure(c(1,1,4,8,12,3,2)/8, names = paste0("r", 1:7)))
})
```

condest

*Compute Approximate CONDition number and 1-Norm of (Large) Matrices*

## Description

“Estimate”, i.e. compute approximately the CONDition number of a (potentially large, often sparse) matrix *A*. It works by apply a fast *randomized* approximation of the 1-norm, `norm(A, "1")`, through `onenormest(.)`.

## Usage

```
condest(A, t = min(n, 5), normA = norm(A, "1"),
        silent = FALSE, quiet = TRUE)

onenormest(A, t = min(n, 5), A.x, At.x, n,
           silent = FALSE, quiet = silent,
           iter.max = 10, eps = 4 * .Machine$double.eps)
```

## Arguments

|                        |   |
|------------------------|---|
| <code>A</code>         | a square matrix, optional for <code>onenormest()</code> , where instead of <code>A</code> , <code>A.x</code> and <code>At.x</code> can be specified, see there. |
| <code>t</code>         | number of columns to use in the iterations.   |
| <code>normA</code>     | number; (an estimate of) the 1-norm of <code>A</code> , by default <code>norm(A, "1")</code> ; may be replaced by an estimate.                                  |
| <code>silent</code>    | logical indicating if warning and (by default) convergence messages should be displayed.  |
| <code>quiet</code>     | logical indicating if convergence messages should be displayed.   |
| <code>A.x, At.x</code> | when <code>A</code> is missing, these two must be given as functions which compute <code>A % x</code> , or <code>t(A) % x</code> , respectively.                |
| <code>n</code>         | <code>== nrow(A)</code> , only needed when <code>A</code> is not specified.   |
| <code>iter.max</code>  | maximal number of iterations for the 1-norm estimator.  |
| <code>eps</code>       | the relative change that is deemed irrelevant.  |

## Details

`condest()` calls `lu(A)`, and subsequently `onenormest(A.x = , At.x =)` to compute an approximate norm of the *inverse* of `A`,  $A^{-1}$ , in a way which keeps using sparse matrices efficiently when `A` is sparse.

Note that `onenormest()` uses random vectors and hence *both* functions' results are random, i.e., depend on the random seed, see, e.g., `set.seed()`.

## Value

Both functions return a `list`; `condest()` with components,

|                  |   |
|------------------|---|
| <code>est</code> | a number $> 0$ , the estimated (1-norm) condition number $\hat{\kappa}$ ; when $r := \text{rcond}(A)$ , $1/\hat{\kappa} \approx r$ .  |
| <code>v</code>   | the maximal $Ax$ column, scaled to $\text{norm}(v) = 1$ . Consequently, $\text{norm}(Av) = \text{norm}(A)/\text{est}$ ; when <code>est</code> is large, <code>v</code> is an approximate null vector. |

The function `onenormest()` returns a list with components,

|                   |  |
|-------------------|--|
| <code>est</code>  | a number $> 0$ , the estimated <code>norm(A, "1")</code> .   |
| <code>v</code>    | 0-1 integer vector length <code>n</code> , with an 1 at the index <code>j</code> with maximal column <code>A[, j]</code> in <code>A</code> . |
| <code>w</code>    | numeric vector, the largest $Ax$ found.  |
| <code>iter</code> | the number of iterations used.   |

## Author(s)

This is based on octave's `condest()` and `onenormest()` implementations with original author Jason Riedy, U Berkeley; translation to R and adaption by Martin Maechler.

str(one) ## est = 12.3
## the maximal column:
which(one$v == 1) # mostly 4, rarely 1, depending on random seed
```

---

CsparseMatrix-class

*Class "CsparseMatrix" of Sparse Matrices in Column-compressed Form*

---

**Description**

The "CsparseMatrix" class is the virtual class of all sparse matrices coded in sorted compressed column-oriented form. Since it is a virtual class, no objects may be created from it. See `showClass("CsparseMatrix")` for its subclasses.

**Slots**

**i:** Object of class "integer" of length `nnzero` (number of non-zero elements). These are the *0-based* row numbers for each non-zero element in the matrix, i.e., `i` must be in `0:(nrow(.)-1)`.

**p:** [integer](#) vector for providing pointers, one for each column, to the initial (zero-based) index of elements in the column. `.@p` is of length `ncol(.) + 1`, with `p[1] == 0` and `p[length(p)] == nnzero`, such that in fact, `diff(.@p)` are the number of non-zero elements for each column.

In other words, `m@p[1:ncol(m)]` contains the indices of those elements in `m@x` that are the first elements in the respective column of `m`.

**Dim, Dimnames:** inherited from the superclass, see the [sparseMatrix](#) class.

**Extends**

Class "sparseMatrix", directly. Class "Matrix", by class "sparseMatrix".

## Methods

matrix products `%*%`, `crossprod()` and `tcrossprod()`, several `solve` methods, and other matrix methods available:

```
signature(e1 = "CsparseMatrix", e2 = "numeric"): ...
AAwith signature(e1 = "numeric", e2 = "CsparseMatrix"): ...
Math signature(x = "CsparseMatrix"): ...
band signature(x = "CsparseMatrix"): ...
- signature(e1 = "CsparseMatrix", e2 = "numeric"): ...
- signature(e1 = "numeric", e2 = "CsparseMatrix"): ...
+ signature(e1 = "CsparseMatrix", e2 = "numeric"): ...
+ signature(e1 = "numeric", e2 = "CsparseMatrix"): ...
coerce signature(from = "CsparseMatrix", to = "TsparseMatrix"): ...
coerce signature(from = "CsparseMatrix", to = "denseMatrix"): ...
coerce signature(from = "CsparseMatrix", to = "matrix"): ...
coerce signature(from = "TsparseMatrix", to = "CsparseMatrix"): ...
coerce signature(from = "denseMatrix", to = "CsparseMatrix"): ...
diag signature(x = "CsparseMatrix"): ...
gamma signature(x = "CsparseMatrix"): ...
lgamma signature(x = "CsparseMatrix"): ...
log signature(x = "CsparseMatrix"): ...
t signature(x = "CsparseMatrix"): ...
tril signature(x = "CsparseMatrix"): ...
triu signature(x = "CsparseMatrix"): ...
```

## Note

All classes extending `CsparseMatrix` have a common validity (see `validObject`) check function. That function additionally checks the `i` slot for each column to contain increasing row numbers.

In earlier versions of **Matrix** ( $\leq 0.999375-16$ ), `validObject` automatically re-sorted the entries when necessary, and hence `new()` calls with somewhat permuted `i` and `x` slots worked, as `new(...)` (*with* slot arguments) automatically checks the validity.

Now, you have to use `sparseMatrix` to achieve the same functionality or know how to use `.validateCsparse()` to do so.

## See Also

`colSums`, `kronecker`, and other such methods with own help pages.

Further, the super class of `CsparseMatrix`, `sparseMatrix`, and, e.g., class `dgCMatrix` for the links to other classes.

## Examples

```

---

ddenseMatrix-class    *Virtual Class "ddenseMatrix" of Numeric Dense Matrices*

---

### Description

This is the virtual class of all dense numeric (i.e., **double**, hence “*ddense*”) S4 matrices.

Its most important subclass is the [dgeMatrix](#) class.

### Extends

Class "dMatrix" directly; class "Matrix", by the above.

### Slots

the same slots at its subclass [dgeMatrix](#), see there.

### Methods

Most methods are implemented via `as(*, "generalMatrix")` and are mainly used as “fall-backs” when the subclass doesn’t need its own specialized method.

Use `showMethods(class = "ddenseMatrix", where = "package:Matrix")` for an overview.

### See Also

The virtual classes [Matrix](#), [dMatrix](#), and [dsparseMatrix](#).

### Examples

```
showClass("ddenseMatrix")

showMethods(class = "ddenseMatrix", where = "package:Matrix")
```

---

ddiMatrix-class    *Class "ddiMatrix" of Diagonal Numeric Matrices*

---

### Description

The class "ddiMatrix" of numerical diagonal matrices. Note that diagonal matrices now extend `sparseMatrix`, whereas they did extend dense matrices earlier.

### Objects from the Class

Objects can be created by calls of the form `new("ddiMatrix", ...)` but typically rather via [Diagonal](#).

**Slots**

**x:** numeric vector. For an  $n \times n$  matrix, the **x** slot is of length  $n$  or 0, depending on the **diag** slot:  
**diag:** "character" string, either "U" or "N" where "U" denotes unit-diagonal, i.e., identity matrices.

**Dim,Dimnames:** matrix dimension and **dimnames**, see the [Matrix](#) class description.

**Extends**

Class "[diagonalMatrix](#)", directly. Class "[dMatrix](#)", directly. Class "[sparseMatrix](#)", indirectly, see [showClass](#)("dDiMatrix").

**Methods**

`%*%` signature(x = "dDiMatrix", y = "dDiMatrix"): ...

**See Also**

Class [diagonalMatrix](#) and function [Diagonal](#).

**Examples**

```
(d2 <- Diagonal(x = c(10,1)))
str(d2)
## slightly larger in internal size:
str(as(d2, "sparseMatrix"))

M <- Matrix(cbind(1,2:4))
M %*% d2 #> `fast' multiplication

chol(d2) # trivial
stopifnot(is(cd2 <- chol(d2), "dDiMatrix"),
  all.equal(cd2@x, c(sqrt(10),1)))
```

---

denseLU-class

*Dense LU Factorizations*

---

**Description**

`denseLU` is the class of dense, row-pivoted LU factorizations of  $m \times n$  real matrices  $A$ , having the general form

$$P_1 A = LU$$

or (equivalently)

$$A = P_1' LU$$

where  $P_1$  is an  $m \times m$  permutation matrix,  $L$  is an  $m \times \min(m, n)$  unit lower trapezoidal matrix, and  $U$  is a  $\min(m, n) \times n$  upper trapezoidal matrix. If  $m = n$ , then the factors  $L$  and  $U$  are triangular.

## Slots

`Dim`, `Dimnames` inherited from virtual class `MatrixFactorization`.

`x` a numeric vector of length `prod(Dim)` storing the triangular  $L$  and  $U$  factors together in a packed format. The details of the representation are specified by the manual for LAPACK routine `dgetrf`.

`perm` an integer vector of length `min(Dim)` specifying the permutation  $P_1$  as a product of transpositions. The corresponding permutation vector can be obtained as `asPerm(perm)`.

## Extends

Class `LU`, directly. Class `MatrixFactorization`, by class `LU`, distance 2.

## Instantiation

Objects can be generated directly by calls of the form `new("denseLU", ...)`, but they are more typically obtained as the value of `lu(x)` for `x` inheriting from `denseMatrix` (often `dgeMatrix`).

## Methods

`coerce` signature(`from` = "denseLU", `to` = "dgeMatrix"): returns a `dgeMatrix` with the dimensions of the factorized matrix  $A$ , equal to  $L$  below the diagonal and equal to  $U$  on and above the diagonal.

`determinant` signature(`from` = "denseLU", `logarithm` = "logical"): computes the determinant of the factorized matrix  $A$  or its logarithm.

`expand` signature(`x` = "denseLU"): see [expand-methods](#).

`expand1` signature(`x` = "denseLU"): see [expand1-methods](#).

`expand2` signature(`x` = "denseLU"): see [expand2-methods](#).

`solve` signature(`a` = "denseLU", `b` = "missing"): see [solve-methods](#).

## References

## See Also

Class `sparseLU` for sparse LU factorizations.

Class `dgeMatrix`.

Generic functions `lu`, `expand1` and `expand2`.

## Examples

```
showClass("denseLU")
set.seed(1)

n <- 3L
(A <- Matrix(round(rnorm(n * n), 2L), n, n))
```

```
## With dimnames, to see that they are propagated :
dimnames(A) <- dn <- list(paste0("r", seq_len(n)),
                          paste0("c", seq_len(n)))

(lu.A <- lu(A))
str(e.lu.A <- expand2(lu.A), max.level = 2L)

## Underlying LAPACK representation
(m.lu.A <- as(lu.A, "dgeMatrix")) # which is L and U interlaced
stopifnot(identical(as(m.lu.A, "matrix"), `dim<-`(lu.A@x, lu.A@Dim)))

ae1 <- function(a, b, ...) all.equal(as(a, "matrix"), as(b, "matrix"), ...)
ae2 <- function(a, b, ...) ae1(unname(a), unname(b), ...)

## A ~ P1' L U in floating point
stopifnot(exprs = {
  identical(names(e.lu.A), c("P1.", "L", "U"))
  identical(e.lu.A[["P1."]],
    new("pMatrix", Dim = c(n, n), Dimnames = c(dn[1L], list(NULL)),
      margin = 1L, perm = invertPerm(asPerm(lu.A@perm)))
  identical(e.lu.A[["L"]],
    new("dtrMatrix", Dim = c(n, n), Dimnames = list(NULL, NULL),
      uplo = "L", diag = "U", x = lu.A@x))
  identical(e.lu.A[["U"]],
    new("dtrMatrix", Dim = c(n, n), Dimnames = c(list(NULL), dn[2L]),
      uplo = "U", diag = "N", x = lu.A@x))
  ae1(A, with(e.lu.A, P1. %*% L %*% U))
  ae2(A[asPerm(lu.A@perm), ], with(e.lu.A, L %*% U))
})

## Factorization handled as factorized matrix
b <- rnorm(n)
stopifnot(identical(det(A), det(lu.A)),
  identical(solve(A, b), solve(lu.A, b)))
```

---

denseMatrix-class    *Virtual Class "denseMatrix" of All Dense Matrices*

---

## Description

This is the virtual class of all dense (S4) matrices. It partitions into two subclasses [packedMatrix](#) and [unpackedMatrix](#). Alternatively into the (currently) three subclasses [ddenseMatrix](#), [ldenseMatrix](#), and [ndenseMatrix](#).

`denseMatrix` is (hence) the direct superclass of these ( $2 + 3 = 5$ ) classes.

## Extends

class "Matrix" directly.

## Slots

exactly those of its superclass "Matrix", i.e., "Dim" and "Dimnames".

## Methods

Use `showMethods(class = "denseMatrix", where = "package:Matrix")` for an overview of methods.

Extraction (`"["`) methods, see [\[-methods\]](#).

## See Also

[colSums](#), [kronecker](#), and other such methods with own help pages.

Its superclass [Matrix](#), and main subclasses, [ddenseMatrix](#) and [sparseMatrix](#).

## Examples

```
showClass("denseMatrix")
```

---

|                 |   |
|-----------------|---|
| dgCMatrix-class | <i>Compressed, sparse, column-oriented numeric matrices</i> |
|-----------------|---|

---

## Description

The `dgCMatrix` class is a class of sparse numeric matrices in the compressed, sparse, column-oriented format. In this implementation the non-zero elements in the columns are sorted into increasing row order. `dgCMatrix` is the “*standard*” class for sparse numeric matrices in the **Matrix** package.

## Objects from the Class

Objects can be created by calls of the form `new("dgCMatrix", ...)`, more typically via `as(*, "CsparseMatrix")` or similar. Often however, more easily via `Matrix(*, sparse = TRUE)`, or most efficiently via `sparseMatrix()`.

## Slots

**x**: Object of class "numeric" - the non-zero elements of the matrix.

**...** all other slots are inherited from the superclass "[CsparseMatrix](#)".

## Methods

Matrix products (e.g., [crossprod-methods](#)), and (among other)

**coerce** signature(`from = "matrix", to = "dgCMatrix"`)

**diag** signature(`x = "dgCMatrix"`): returns the diagonal of `x`

**dim** signature(`x = "dgCMatrix"`): returns the dimensions of `x`

**image** signature(`x = "dgCMatrix"`): plots an image of `x` using the [levelplot](#) function

**solve** signature(`a = "dgCMatrix", b = "..."`): see [solve-methods](#), notably the extra argument `sparse`.

**lu** signature(`x = "dgCMatrix"`): computes the LU decomposition of a square `dgCMatrix` object

**See Also**

Classes [dsCMatrix](#), [dtCMatrix](#), [lu](#)

**Examples**

```
(m <- Matrix(c(0,0,2:0), 3,5))
str(m)
m[,1]
```

---

dgeMatrix-class      *Class "dgeMatrix" of Dense Numeric (S4 Class) Matrices*

---

**Description**

A general numeric dense matrix in the S4 Matrix representation. `dgeMatrix` is the “*standard*” class for dense numeric matrices in the **Matrix** package.

**Objects from the Class**

Objects can be created by calls of the form `new("dgeMatrix", ...)` or, more commonly, by coercion from the `Matrix` class (see [Matrix](#)) or by `Matrix(...)`.

**Slots**

**x:** Object of class "numeric" - the numeric values contained in the matrix, in column-major order.

**Dim:** Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

**Dimnames:** a list of length two - inherited from class [Matrix](#).

**factors:** Object of class "list" - a list of factorizations of the matrix.

**Methods**

The are group methods (see, e.g., [Arith](#))

**Arith** signature(e1 = "dgeMatrix", e2 = "dgeMatrix"): ...

**Arith** signature(e1 = "dgeMatrix", e2 = "numeric"): ...

**Arith** signature(e1 = "numeric", e2 = "dgeMatrix"): ...

**Math** signature(x = "dgeMatrix"): ...

**Math2** signature(x = "dgeMatrix", digits = "numeric"): ...

matrix products `%*%`, `crossprod()` and `tcrossprod()`, several `solve` methods, and other matrix methods available:

**Schur** signature(x = "dgeMatrix", vectors = "logical"): ...

**Schur** signature(x = "dgeMatrix", vectors = "missing"): ...

**chol** signature(x = "dgeMatrix"): see [chol](#).

**colMeans** signature(x = "dgeMatrix"): columnwise means (averages)

```

colSums signature(x = "dgeMatrix"): columnwise sums
diag signature(x = "dgeMatrix"): ...
dim signature(x = "dgeMatrix"): ...
dimnames signature(x = "dgeMatrix"): ...
eigen signature(x = "dgeMatrix", only.values= "logical"): ...
eigen signature(x = "dgeMatrix", only.values= "missing"): ...
norm signature(x = "dgeMatrix", type = "character"): ...
norm signature(x = "dgeMatrix", type = "missing"): ...
rcond signature(x = "dgeMatrix", norm = "character") or norm = "missing":
    the reciprocal condition number, rcond().
rowMeans signature(x = "dgeMatrix"): rowwise means (averages)
rowSums signature(x = "dgeMatrix"): rowwise sums
t signature(x = "dgeMatrix"): matrix transpose

```

### See Also

Classes [Matrix](#), [dtrMatrix](#), and [dsyMatrix](#).

---

dgRMatrix-class

*Sparse Compressed, Row-oriented Numeric Matrices*

---

### Description

The `dgRMatrix` class is a class of sparse numeric matrices in the compressed, sparse, row-oriented format. In this implementation the non-zero elements in the rows are sorted into increasing column order.

**Note:** The column-oriented sparse classes, e.g., [dgCMatrix](#), are preferred and better supported in the **Matrix** package.

### Objects from the Class

Objects can be created by calls of the form `new("dgRMatrix", ...)`.

### Slots

**j:** Object of class "integer" of length `nnzero` (number of non-zero elements). These are the column numbers for each non-zero element in the matrix.

**p:** Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row.

**x:** Object of class "numeric" - the non-zero elements of the matrix.

**Dim:** Object of class "integer" - the dimensions of the matrix.

### Methods

```

diag signature(x = "dgRMatrix"): returns the diagonal of x
dim signature(x = "dgRMatrix"): returns the dimensions of x
image signature(x = "dgRMatrix"): plots an image of x using the levelplot function

```

**See Also**

the [RsparseMatrix](#) class, the virtual class of all sparse compressed row-oriented matrices, with its methods. The [dgCMatrix](#) class (column compressed sparse) is really preferred.

---

dgTMatrix-class      *Sparse matrices in triplet form*

---

**Description**

The "dgTMatrix" class is the class of sparse matrices stored as (possibly redundant) triplets. The internal representation is not at all unique, contrary to the one for class [dgCMatrix](#).

**Objects from the Class**

Objects can be created by calls of the form `new("dgTMatrix", ...)`, but more typically via `spMatrix()` or `sparseMatrix(*, repr = "T")`.

**Slots**

**i:** [integer](#) row indices of non-zero entries *in 0-base*, i.e., must be in `0:(nrow(.)-1)`.  
**j:** [integer](#) column indices of non-zero entries. Must be the same length as slot **i** and *0-based* as well, i.e., in `0:(ncol(.)-1)`.  
**x:** [numeric](#) vector - the (non-zero) entry at position  $(i, j)$ . Must be the same length as slot **i**. If an index pair occurs more than once, the corresponding values of slot **x** are added to form the element of the matrix.  
**Dim:** Object of class "integer" of length 2 - the dimensions of the matrix.

**Methods**

**+** signature(e1 = "dgTMatrix", e2 = "dgTMatrix")  
**image** signature(x = "dgTMatrix"): plots an image of **x** using the [levelplot](#) function  
**t** signature(x = "dgTMatrix"): returns the transpose of **x**

**Note**

Triplet matrices are a convenient form in which to construct sparse matrices after which they can be coerced to [dgCMatrix](#) objects.

Note that both `new(.)` and [spMatrix](#) constructors for "dgTMatrix" (and other "TsparseMatrix" classes) implicitly add  $x_k$ 's that belong to identical  $(i_k, j_k)$  pairs.

However this means that a matrix typically can be stored in more than one possible "TsparseMatrix" representations. Use [asUniqueT\(\)](#) in order to ensure uniqueness of the internal representation of such a matrix.

**See Also**

Class [dgCMatrix](#) or the superclasses [dsparseMatrix](#) and [TsparseMatrix](#); [asUniqueT](#).

**Examples**

```

m <- Matrix(0+1:28, nrow = 4)
m[-3,c(2,4:5,7)] <- m[ 3, 1:4] <- m[1:3, 6] <- 0
(mT <- as(m, "TsparseMatrix"))
str(mT)
mT[1,]
mT[4, drop = FALSE]
stopifnot(identical(mT[lower.tri(mT)],
                    m [lower.tri(m) ]))
mT[lower.tri(mT,diag=TRUE)] <- 0
mT

## Triplet representation with repeated (i,j) entries
## *adds* the corresponding x's:
T2 <- new("dgTMatrix",
          i = as.integer(c(1,1,0,3,3)),
          j = as.integer(c(2,2,4,0,0)), x=10*1:5, Dim=4:5)
str(T2) # contains (i,j,x) slots exactly as above, but
T2 ## has only three non-zero entries, as for repeated (i,j)'s,
     ## the corresponding x's are "implicitly" added
stopifnot(nnzero(T2) == 3)

```

Diagonal

*Construct a Diagonal Matrix***Description**

Construct a formally diagonal [Matrix](#), i.e., an object inheriting from virtual class [diagonalMatrix](#) (or, if desired, a *mathematically* diagonal [CsparseMatrix](#)).

**Usage**

```

Diagonal(n, x = NULL, names = FALSE)

.sparseDiagonal(n, x = NULL, uplo = "U", shape = "t", unitri = TRUE, kind, cols)
.trDiagonal(n, x = NULL, uplo = "U", unitri = TRUE, kind)
.symDiagonal(n, x = NULL, uplo = "U", kind)

```

**Arguments**

|       |   |
|-------|---|
| n     | integer indicating the dimension of the (square) matrix. If missing, then <code>length(x)</code> is used.   |
| x     | numeric or logical vector listing values for the diagonal entries, to be recycled as necessary. If <code>NULL</code> (the default), then the result is a unit diagonal matrix. <code>.sparseDiagonal()</code> and friends ignore non- <code>NULL</code> <code>x</code> when <code>kind = "n"</code> .   |
| names | either <a href="#">logical</a> <code>TRUE</code> or <code>FALSE</code> or then a <a href="#">character</a> vector of <a href="#">length</a> <code>n</code> . If true <i>and</i> <code>names(x)</code> is not <code>NULL</code> , use that as both row and column names for the resulting matrix. When a character vector, use it for both dimnames. |
| uplo  | one of <code>c("U", "L")</code> , specifying the <code>uplo</code> slot of the result if the result is formally triangular or symmetric.  |

|        |  |
|--------|--|
| shape  | one of <code>c("t", "s", "g")</code> , indicating if the result should be formally triangular, symmetric, or “general”. The result will inherit from virtual class <code>triangularMatrix</code> , <code>symmetricMatrix</code> , or <code>generalMatrix</code> , respectively.  |
| unitri | logical indicating if a formally triangular result with ones on the diagonal should be formally <i>unit</i> triangular, i.e., with <code>diag</code> slot equal to <code>"U"</code> rather than <code>"N"</code> .   |
| kind   | one of <code>c("d", "l", "n")</code> , indicating the “mode” of the result: numeric, logical, or pattern. The result will inherit from virtual class <code>dsparseMatrix</code> , <code>lsparseMatrix</code> , or <code>nsparseMatrix</code> , respectively. Values other than <code>"n"</code> are ignored when <code>x</code> is non-NULL; in that case the mode is determined by <code>typeof(x)</code> . |
| cols   | optional integer vector with values in <code>0:(n-1)</code> , indexing columns of the specified diagonal matrix. If specified, then the result is (mathematically) <code>D[, cols+1]</code> rather than <code>D</code> , where <code>D = Diagonal(n, x)</code> , and it is always “general” (i.e., shape is ignored).  |

### Value

`Diagonal()` returns an object inheriting from virtual class `diagonalMatrix`.

`.sparseDiagonal()` returns a `CsparseMatrix` representation of `Diagonal(n, x)` or, if `cols` is given, of `Diagonal(n, x)[, cols+1]`. The precise class of the result depends on shape and kind.

`.trDiagonal()` and `.symDiagonal()` are simple wrappers, for `.sparseDiagonal(shape = "t")` and `.sparseDiagonal(shape = "s")`, respectively.

`.sparseDiagonal()` exists primarily to leverage efficient C-level methods available for `CsparseMatrix`.

### Author(s)

Martin Maechler

### See Also

the generic function `diag` for *extraction* of the diagonal from a matrix works for all “Matrices”.

`bandSparse` constructs a *banded* sparse matrix from its non-zero sub-/super - diagonals.

`band(A)` returns a band matrix containing some sub-/super - diagonals of `A`.

`Matrix` for general matrix construction; further, class `diagonalMatrix`.

### Examples

```
Diagonal(3)
Diagonal(x = 10^(3:1))
Diagonal(x = (1:4) >= 2) #-> "ldiMatrix"

## Use Diagonal() + kronecker() for "repeated-block" matrices:
M1 <- Matrix(0+0:5, 2, 3)
(M <- kronecker(Diagonal(3), M1))

(S <- crossprod(Matrix(rbinom(60, size=1, prob=0.1), 10, 6)))
(SI <- S + 10*.symDiagonal(6)) # sparse symmetric still
stopifnot(is(SI, "dsCMatrix"))
```

```
(I4 <- .sparseDiagonal(4, shape="t"))# now (2012-10) unitriangular
stopifnot(I4@diag == "U", all(I4 == diag(4)))
```

---

diagonalMatrix-class

*Class "diagonalMatrix" of Diagonal Matrices*

---

## Description

Class "diagonalMatrix" is the virtual class of all diagonal matrices.

## Objects from the Class

A virtual Class: No objects may be created from it.

## Slots

**diag:** [character](#) string, either "U" or "N", where "U" means ‘unit-diagonal’.

**Dim:** matrix dimension, and

**Dimnames:** the [dimnames](#), a [list](#), see the [Matrix](#) class description. Typically `list(NULL, NULL)` for diagonal matrices.

## Extends

Class "[sparseMatrix](#)", directly.

## Methods

These are just a subset of the signature for which defined methods. Currently, there are (too) many explicit methods defined in order to ensure efficient methods for diagonal matrices.

**coerce** signature(from = "matrix", to = "diagonalMatrix"): ...

**coerce** signature(from = "Matrix", to = "diagonalMatrix"): ...

**coerce** signature(from = "diagonalMatrix", to = "generalMatrix"): ...

**coerce** signature(from = "diagonalMatrix", to = "triangularMatrix"): ...

**coerce** signature(from = "diagonalMatrix", to = "nMatrix"): ...

**coerce** signature(from = "diagonalMatrix", to = "matrix"): ...

**coerce** signature(from = "diagonalMatrix", to = "sparseVector"): ...

**t** signature(x = "diagonalMatrix"): ...

and many more methods

**solve** signature(a = "diagonalMatrix", b, ...): is trivially implemented, of course; see also [solve-methods](#).

**which** signature(x = "nMatrix"), semantically equivalent to **base** function [which](#)(x, arr.ind).

**"Math"** signature(x = "diagonalMatrix"): all these group methods return a "diagonalMatrix", apart from [cumsum](#)() etc which return a *vector* also for **base** [matrix](#).

```
* signature(e1 = "ddiMatrix", e2="denseMatrix"): arithmetic and other operators
  from the Ops group have a few dozen explicit method definitions, in order to keep the results
  diagonal in many cases, including the following:

/ signature(e1 = "ddiMatrix", e2="denseMatrix"): the result is from class
  ddiMatrix which is typically very desirable. Note that when e2 contains off-diagonal
  zeros or NAs, we implicitly use  $0/x = 0$ , hence differing from traditional R arithmetic (where
   $0/0 \mapsto \text{NaN}$ ), in order to preserve sparsity.

summary (object = "diagonalMatrix"): Returns an object of S3 class
  "diagSummary" which is the summary of the vector object@x plus a simple heading,
  and an appropriate print method.
```

### See Also

`Diagonal()` as constructor of these matrices, and `isDiagonal`. `ddiMatrix` and `ldiMatrix` are “actual” classes extending “diagonalMatrix”.

### Examples

```
I5 <- Diagonal(5)
D5 <- Diagonal(x = 10*(1:5))
## trivial (but explicitly defined) methods:
stopifnot(identical(crossprod(I5), I5),
           identical(tcrossprod(I5), I5),
           identical(crossprod(I5, D5), D5),
           identical(tcrossprod(D5, I5), D5),
           identical(solve(D5), solve(D5, I5)),
           all.equal(D5, solve(solve(D5)), tolerance = 1e-12)
)
solve(D5) # efficient as is diagonal

# an unusual way to construct a band matrix:
rbind2(cbind2(I5, D5),
       cbind2(D5, I5))
```

---

diagU2N

*Transform Triangular Matrices from Unit Triangular to General Triangular and Back*

---

### Description

Transform a triangular matrix `x`, i.e., of class `triangularMatrix`, from (internally!) unit triangular (“unitriangular”) to “general” triangular (`diagU2N(x)`) or back (`diagN2U(x)`). Note that the latter, `diagN2U(x)`, also sets the diagonal to one in cases where `diag(x)` was not all one.

`.diagU2N(x)` and `.diagN2U(x)` assume *without* checking that `x` is a `triangularMatrix` with suitable `diag` slot (“U” and “N”, respectively), hence they should be used with care.

**Usage**

```
diagU2N(x, cl = getClassDef(class(x)), checkDense = FALSE)
diagN2U(x, cl = getClassDef(class(x)), checkDense = FALSE)

.diagU2N(x, cl = getClassDef(class(x)), checkDense = FALSE)
.diagN2U(x, cl = getClassDef(class(x)), checkDense = FALSE)
```

**Arguments**

|                         |  |
|-------------------------|--|
| <code>x</code>          | a <code>triangularMatrix</code> , often sparse.  |
| <code>cl</code>         | (optional, for speedup only:) class (definition) of <code>x</code> .   |
| <code>checkDense</code> | logical indicating if dense (see <code>denseMatrix</code> ) matrices should be considered at all; i.e., when false, as per default, the result will be sparse even when <code>x</code> is dense. |

**Details**

The concept of unit triangular matrices with a `diag` slot of "U" stems from LAPACK.

**Value**

a triangular matrix of the same `class` but with a different `diag` slot. For `diagU2N` (semantically) with identical entries as `x`, whereas in `diagN2U(x)`, the off-diagonal entries are unchanged and the diagonal is set to all 1 even if it was not previously.

**Note**

Such internal storage details should rarely be of relevance to the user. Hence, these functions really are rather *internal* utilities.

**See Also**

"`triangularMatrix`", "`dtCMatrix`".

**Examples**

```
(T <- Diagonal(7) + triu(Matrix(rpois(49, 1/4), 7, 7), k = 1))
(uT <- diagN2U(T)) # "unittriangular"
(t.u <- diagN2U(10*T)) # changes the diagonal!
stopifnot(all(T == uT), diag(t.u) == 1,
           identical(T, diagU2N(uT)))
T[upper.tri(T)] <- 5 # still "dtC"
T <- diagN2U(as(T, "triangularMatrix"))
dT <- as(T, "denseMatrix") # (unittriangular)
dT.n <- diagU2N(dT, checkDense = TRUE)
sT.n <- diagU2N(dT)
stopifnot(is(dT.n, "denseMatrix"), is(sT.n, "sparseMatrix"),
          dT@diag == "U", dT.n@diag == "N", sT.n@diag == "N",
          all(dT == dT.n), all(dT == sT.n))
```

dimScale

*Scale the Rows and Columns of a Matrix***Description**

`dimScale`, `rowScale`, and `colScale` implement  $D1 \%*\% x \%*\% D2$ ,  $D \%*\% x$ , and  $x \%*\% D$  for diagonal matrices  $D1$ ,  $D2$ , and  $D$  with diagonal entries `d1`, `d2`, and `d`, respectively. Unlike the explicit products, these functions preserve `dimnames(x)` and symmetry where appropriate.

**Usage**

```
dimScale(x, d1 = sqrt(1/diag(x, names = FALSE)), d2 = d1)
rowScale(x, d)
colScale(x, d)
```

**Arguments**

`x` a matrix, possibly inheriting from virtual class `Matrix`.

`d1`, `d2`, `d` numeric vectors giving factors by which to scale the rows or columns of `x`; they are recycled as necessary.

**Details**

`dimScale(x)` (with `d1` and `d2` unset) is only roughly equivalent to `cov2cor(x)`. `cov2cor` sets the diagonal entries of the result to 1 (exactly); `dimScale` does not.

**Value**

The result of scaling `x`, currently always inheriting from virtual class `dMatrix`.

It inherits from `triangularMatrix` if and only if `x` does. In the special case of `dimScale(x, d1, d2)` with identical `d1` and `d2`, it inherits from `symmetricMatrix` if and only if `x` does.

**Author(s)**

Mikael Jagan

**See Also**

`cov2cor`

**Examples**

```
n <- 6L
(x <- forceSymmetric(matrix(1, n, n)))
dimnames(x) <- rep.int(list(letters[seq_len(n)]), 2L)

d <- seq_len(n)
(D <- Diagonal(x = d))

(scx <- dimScale(x, d)) # symmetry and 'dimnames' kept
(mmx <- D \%*\% x \%*\% D) # symmetry and 'dimnames' lost
stopifnot(identical(unname(as(scx, "generalMatrix")), mmx))
```

```
rowScale(x, d)
colScale(x, d)
```

---

dMatrix-class      (Virtual) Class "dMatrix" of "double" Matrices

---

## Description

The `dMatrix` class is a virtual class contained by all actual classes of numeric matrices in the **Matrix** package. Similarly, all the actual classes of logical matrices inherit from the `lMatrix` class.

## Slots

Common to *all* matrix object in the package:

**Dim:** Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

**Dimnames:** list of length two; each component containing NULL or a `character` vector length equal the corresponding `Dim` element.

## Methods

There are (relatively simple) group methods (see, e.g., [Arith](#))

**Arith** signature(e1 = "dMatrix", e2 = "dMatrix"): ...

**Arith** signature(e1 = "dMatrix", e2 = "numeric"): ...

**Arith** signature(e1 = "numeric", e2 = "dMatrix"): ...

**Math** signature(x = "dMatrix"): ...

**Math2** signature(x = "dMatrix", digits = "numeric"):    this    group    contains [round\(\)](#) and [signif\(\)](#).

**Compare** signature(e1 = "numeric", e2 = "dMatrix"): ...

**Compare** signature(e1 = "dMatrix", e2 = "numeric"): ...

**Compare** signature(e1 = "dMatrix", e2 = "dMatrix"): ...

**Summary** signature(x = "dMatrix"): The "Summary" group contains the seven functions [max\(\)](#), [min\(\)](#), [range\(\)](#), [prod\(\)](#), [sum\(\)](#), [any\(\)](#), and [all\(\)](#).

The following methods are also defined for all double matrices:

**expm** signature(x = "dMatrix"): computes the "Matrix Exponential", see [expm](#).

The following methods are defined for all logical matrices:

**which** signature(x = "lsparseMatrix") and many other subclasses of "lMatrix": as the **base** function [which](#)(x, arr.ind) returns the indices of the `TRUE` entries in x; if `arr.ind` is true, as a 2-column matrix of row and column indices. Since **Matrix** version 1.2-9, if `useNames` is true, as by default, with [dimnames](#), the same as `base::which`.

## See Also

The nonzero-pattern matrix class `nMatrix`, which can be used to store non-NA logical matrices even more compactly.

The numeric matrix classes `dgeMatrix`, `dgCMatrix`, and `Matrix`.

`drop0(x, tol=1e-10)` is sometimes preferable to (and more efficient than) `zapsmall(x, digits=10)`.

## Examples

```
showClass("dMatrix")

set.seed(101)
round(Matrix(rnorm(28), 4, 7), 2)
M <- Matrix(rlnorm(56, sd=10), 4, 14)
(M. <- zapsmall(M))
table(as.logical(M. == 0))
```

---

dmperm

*Dulmage-Mendelsohn Permutation / Decomposition*

---

## Description

For any  $n \times m$  (typically) sparse matrix `x` compute the Dulmage-Mendelsohn row and columns permutations which at first splits the  $n$  rows and  $m$  columns into coarse partitions each; and then a finer one, reordering rows and columns such that the permuted matrix is “as upper triangular” as possible.

## Usage

```
dmperm(x, nAns = 6L, seed = 0L)
```

## Arguments

|                   |  |
|-------------------|--|
| <code>x</code>    | a typically sparse matrix; internally coerced to either <code>"dgCMatrix"</code> or <code>"dtCMatrix"</code> .   |
| <code>nAns</code> | an integer specifying the <code>length</code> of the resulting <code>list</code> . Must be 2, 4, or 6.   |
| <code>seed</code> | an integer code in -1,0,1; determining the (initial) permutation; by default, <code>seed = 0</code> , no (or the identity) permutation; <code>seed = -1</code> uses the “reverse” permutation <code>k:1</code> ; for <code>seed = 1</code> , it is a <i>random</i> permutation (using R’s RNG, seed, etc). |

## Details

See the book section by Tim Davis; page 122–127, in the References.

**Value**

a named `list` with (by default) 6 components,

|                  |   |
|------------------|---|
| <code>p</code>   | integer vector with the permutation <code>p</code> , of length <code>nrow(x)</code> .   |
| <code>q</code>   | integer vector with the permutation <code>q</code> , of length <code>ncol(x)</code> .   |
| <code>r</code>   | integer vector of length <code>nb+1</code> , where block <code>k</code> is rows <code>r[k]</code> to <code>r[k+1]-1</code> in <code>A[p,q]</code> . |
| <code>s</code>   | integer vector of length <code>nb+1</code> , where block <code>k</code> is cols <code>s[k]</code> to <code>s[k+1]-1</code> in <code>A[p,q]</code> . |
| <code>rr5</code> | integer vector of length 5, defining the coarse row decomposition.  |
| <code>cc5</code> | integer vector of length 5, defining the coarse column decomposition.   |

**Author(s)**

Martin Maechler, with a lot of “encouragement” by Mauricio Vargas.

**Examples**

```
set.seed(17)
(S9 <- rsparsematrix(9, 9, nnz = 10, symmetric=TRUE)) # dsCMatrix
str( dm9 <- dmperm(S9) )
(S9p <- with(dm9, S9[p, q]))
## looks good, but *not* quite upper triangular; these, too:
str( dm9.0 <- dmperm(S9, seed=-1)) # non-random too.
str( dm9_1 <- dmperm(S9, seed= 1)) # a random one
## The last two permutations differ, but have the same effect!
(S9p0 <- with(dm9.0, S9[p, q])) # .. hmm ..
stopifnot(all.equal(S9p0, S9p)) # same as as default, but different from the random one

set.seed(11)
(M <- triu(rsparsematrix(9,11, 1/4)))
dM <- dmperm(M); with(dM, M[p, q])
(Mp <- M[sample.int(nrow(M)), sample.int(ncol(M))])
dMp <- dmperm(Mp); with(dMp, Mp[p, q])

set.seed(7)
(n7 <- rsparsematrix(5, 12, nnz = 10, rand.x = NULL))
str( dm.7 <- dmperm(n7) )
stopifnot(exprs = {
  lengths(dm.7[1:2]) == dim(n7)
  identical(dm.7, dmperm(as(n7, "dMatrix")))
  identical(dm.7[1:4], dmperm(n7, nAns=4))
  identical(dm.7[1:2], dmperm(n7, nAns=2))
})
```

---

dpoMatrix-class      *Positive Semi-definite Dense (Packed | Non-packed) Numeric Matrices*

---

### Description

- The "dpoMatrix" class is the class of positive-semidefinite symmetric matrices in non-packed storage.
- The "dppMatrix" class is the same except in packed storage. Only the upper triangle or the lower triangle is required to be available.
- The "corMatrix" and "copMatrix" classes represent correlation matrices. They extend "dpoMatrix" and "dppMatrix", respectively, with an additional slot `sd` allowing restoration of the original covariance matrix.

### Objects from the Class

Objects can be created by calls of the form `new("dpoMatrix", ...)` or from `crossprod` applied to an "dgeMatrix" object.

### Slots

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**x:** Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order.

**Dim:** Object of class "integer". The dimensions of the matrix which must be a two-element vector of non-negative integers.

**Dimnames:** inherited from class "Matrix"

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

**sd:** (for "corMatrix" and "copMatrix") a [numeric](#) vector of length `n` containing the (original)  $\sqrt{\text{var}(\cdot)}$  entries which allow reconstruction of a covariance matrix from the correlation matrix.

### Extends

Class "dsyMatrix", directly.  
Classes "dgeMatrix", "symmetricMatrix", and many more by class "dsyMatrix".

### Methods

**chol** signature (`x = "dpoMatrix"`): Returns (and stores) the Cholesky decomposition of `x`, see [chol](#).

**determinant** signature (`x = "dpoMatrix"`): Returns the [determinant](#) of `x`, via `chol(x)`, see above.

**rcond** signature (`x = "dpoMatrix"`, `norm = "character"`): Returns (and stores) the reciprocal of the condition number of `x`. The `norm` can be "O" for the one-norm (the default) or "I" for the infinity-norm. For symmetric matrices the result does not depend on the norm.

**solve** signature (`a = "dpoMatrix"`, `b = "..."`), and

**solve** signature(`a = "dppMatrix"`, `b = "..."`) work via the Cholesky composition, see also the Matrix [solve-methods](#).

**Arith** signature(`e1 = "dpoMatrix"`, `e2 = "numeric"`) (and quite a few other signatures): The result of (“elementwise” defined) arithmetic operations is typically *not* positive-definite anymore. The only exceptions, currently, are multiplications, divisions or additions with *positive* `length(.) == 1` numbers (or [logicals](#)).

### Note

Currently the validity methods for these classes such as [getValidity](#)(`getClass("dpoMatrix")`) for efficiency reasons only check the diagonal entries of the matrix – they may not be negative. This is only necessary but not sufficient for a symmetric matrix to be positive semi-definite.

A more reliable (but often more expensive) check for positive semi-definiteness would look at the signs of `diag(BunchKaufman(.))` (with some tolerance for very small negative values), and for (strict) positive definiteness at something like `!inherits(tryCatch(chol(.), error=identity), "error")`. Indeed, when *coercing* to these classes, a version of [Cholesky\(\)](#) or [chol\(\)](#) is typically used, e.g., see `selectMethod("coerce", c(from="dsyMatrix", to="dpoMatrix"))`.

### See Also

Classes [dsyMatrix](#) and [dgeMatrix](#); further, [Matrix](#), [rcond](#), [chol](#), [solve](#), [crossprod](#).

### Examples

```
h6 <- Hilbert(6)
rcond(h6)
str(h6)
h6 * 27720 # is ``integer``
solve(h6)
str(hp6 <- pack(h6))

### Note that as(*, "corMatrix") *scales* the matrix
(ch6 <- as(h6, "corMatrix"))
stopifnot(all.equal(as(h6 * 27720, "dsyMatrix"), round(27720 * h6),
                    tolerance = 1e-14),
           all.equal(ch6@sd^(-2), 2*(1:6)-1,
                    tolerance = 1e-12))
chch <- Cholesky(ch6, perm = FALSE)
stopifnot(identical(chch, ch6@factors$Cholesky),
           all(abs(crossprod(as(chch, "dtrMatrix")) - ch6) < 1e-10))
```

### Description

Deletes “non-structural” zeros (i.e., zeros stored explicitly, in memory) from a sparse matrix and returns the result.

**Usage**

```
drop0(x, tol = 0, is.Csparse = NA, give.Csparse = TRUE)
```

**Arguments**

**x** a [Matrix](#), typically inheriting from virtual class [sparseMatrix](#). [denseMatrix](#) and traditional vectors and matrices are coerced to [CsparseMatrix](#), with zeros dropped automatically, hence users passing such **x** should consider as `(x, "CsparseMatrix")` instead, notably in the `tol = 0` case.

**tol** a non-negative number. If **x** is numeric, then entries less than or equal to **tol** in absolute value are deleted.

**is.Csparse** a logical used only if `give.Csparse` is `TRUE`, indicating if **x** already inherits from virtual class [CsparseMatrix](#), in which case coercion is not attempted, permitting some (typically small) speed-up.

**give.Csparse** a logical indicating if the result must inherit from virtual class [CsparseMatrix](#). If `FALSE` and **x** inherits from [RsparseMatrix](#), [TsparseMatrix](#), or [indMatrix](#), then the result preserves the class of **x**. The default value is `TRUE` only for backwards compatibility.

**Value**

A [sparseMatrix](#), the result of deleting non-structural zeros from **x**, possibly after coercion.

**Note**

`drop0` is sometimes called in conjunction with [zapsmall](#), e.g., when dealing with sparse matrix products; see the example.

**See Also**

Function [sparseMatrix](#), for constructing objects inheriting from virtual class [sparseMatrix](#); [nnzero](#).

**Examples**

```
(m <- sparseMatrix(i = 1:8, j = 2:9, x = c(0:2, 3:-1),
                  dims = c(10L, 20L)))
drop0(m)

## A larger example:
t5 <- new("dtCMatrix", Dim = c(5L, 5L), uplo = "L",
        x = c(10, 1, 3, 10, 1, 10, 1, 10, 10),
        i = c(0L,2L,4L, 1L, 3L,2L,4L, 3L, 4L),
        p = c(0L, 3L, 5L, 7:9))
TT <- kronecker(t5, kronecker(kronecker(t5, t5), t5))
IT <- solve(TT)
I. <- TT %*% IT ; nnzero(I.) # 697 ( == 625 + 72 )
I.0 <- drop0(zapsmall(I.))
## which actually can be more efficiently achieved by
I.. <- drop0(I., tol = 1e-15)
stopifnot(all(I.0 == Diagonal(625)), nnzero(I..) == 625)
```

---

dsCMatrix-class      *Numeric Symmetric Sparse (column compressed) Matrices*

---

## Description

The `dsCMatrix` class is a class of symmetric, sparse numeric matrices in the compressed, column-oriented format. In this implementation the non-zero elements in the columns are sorted into increasing row order.

The `dsTMatrix` class is the class of symmetric, sparse numeric matrices in triplet format.

## Objects from the Class

Objects can be created by calls of the form `new("dsCMatrix", ...)` or `new("dsTMatrix", ...)`, or automatically via e.g., `as(*, "symmetricMatrix")`, or (for `dsCMatrix`) also from `Matrix(.)`.

Creation “from scratch” most efficiently happens via `sparseMatrix(*, symmetric=TRUE)`.

## Slots

**uplo:** A character object indicating if the upper triangle ("U") or the lower triangle ("L") is stored.

**i:** Object of class "integer" of length `nnZ` (*half* number of non-zero elements). These are the row numbers for each non-zero element in the lower triangle of the matrix.

**p:** (only in class "dsCMatrix":) an `integer` vector for providing pointers, one for each column, see the detailed description in `CsparseMatrix`.

**j:** (only in class "dsTMatrix":) Object of class "integer" of length `nnZ` (as `i`). These are the column numbers for each non-zero element in the lower triangle of the matrix.

**x:** Object of class "numeric" of length `nnZ` – the non-zero elements of the matrix (to be duplicated for full matrix).

**factors:** Object of class "list" - a list of factorizations of the matrix.

**Dim:** Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

## Extends

Both classes extend classes and `symmetricMatrix` `dsparseMatrix` directly; `dsCMatrix` further directly extends `CsparseMatrix`, where `dsTMatrix` does `TsparseMatrix`.

## Methods

**solve** signature (`a = "dsCMatrix"`, `b = "..."`): `x <- solve(a,b)` solves  $Ax = b$  for  $x$ ; see `solve-methods`.

**chol** signature (`x = "dsCMatrix"`, `pivot = "logical"`): Returns (and stores) the Cholesky decomposition of  $x$ , see `chol`.

**Cholesky** signature (`A = "dsCMatrix"`, ...): Computes more flexibly Cholesky decompositions, see `Cholesky`.

**determinant** signature (`x = "dsCMatrix"`, `logarithm = "missing"`): Evaluate the determinant of  $x$  on the logarithm scale. This creates and stores the Cholesky factorization.

- determinant** signature(x = "dsCMatrix", logarithm = "logical"): Evaluate the determinant of x on the logarithm scale or not, according to the logarithm argument. This creates and stores the Cholesky factorization.
- t** signature(x = "dsCMatrix"): Transpose. As for all symmetric matrices, a matrix for which the upper triangle is stored produces a matrix for which the lower triangle is stored and vice versa, i.e., the uplo slot is swapped, and the row and column indices are interchanged.
- t** signature(x = "dsTMatrix"): Transpose. The uplo slot is swapped from "U" to "L" or vice versa, as for a "dsCMatrix", see above.

### See Also

Classes [dgCMatrix](#), [dgTMatrix](#), [dgeMatrix](#) and those mentioned above.

### Examples

```
mm <- Matrix(toeplitz(c(10, 0, 1, 0, 3)), sparse = TRUE)
mm # automatically dsCMatrix
str(mm)
mT <- as(as(mm, "generalMatrix"), "TsparseMatrix")

## Either
(symM <- as(mT, "symmetricMatrix")) # dsT
(symC <- as(symM, "CsparseMatrix")) # dsC
## or
sT <- Matrix(mT, sparse=TRUE, forceCheck=TRUE) # dsT

sym2 <- as(symC, "TsparseMatrix")
## --> the same as 'symM', a "dsTMatrix"
```

---

dsparseMatrix-class

*Virtual Class "dsparseMatrix" of Numeric Sparse Matrices*

---

### Description

The Class "dsparseMatrix" is the virtual (super) class of all numeric sparse matrices.

### Slots

**Dim:** the matrix dimension, see class "[Matrix](#)".

**Dimnames:** see the "[Matrix](#)" class.

**x:** a [numeric](#) vector containing the (non-zero) matrix entries.

### Extends

Class "[dMatrix](#)" and "[sparseMatrix](#)", directly.

Class "[Matrix](#)", by the above classes.

### See Also

the documentation of the (non virtual) sub classes, see `showClass("dsparseMatrix")`; in particular, [dgTMatrix](#), [dgCMatrix](#), and [dgRMatrix](#).

**Examples**

```
showClass("dsparseMatrix")
```

---

|                 |   |
|-----------------|---|
| dsRMatrix-class | <i>Symmetric Sparse Compressed Row Matrices</i> |
|-----------------|---|

---

**Description**

The `dsRMatrix` class is a class of symmetric, sparse matrices in the compressed, row-oriented format. In this implementation the non-zero elements in the rows are sorted into increasing column order.

**Objects from the Class**

These `"..RMatrix"` classes are currently still mostly unimplemented!

Objects can be created by calls of the form `new("dsRMatrix", ...)`.

**Slots**

**uplo:** A character object indicating if the upper triangle ("U") or the lower triangle ("L") is stored. At present only the lower triangle form is allowed.

**j:** Object of class `"integer"` of length `nnzero` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.

**p:** Object of class `"integer"` of pointers, one for each row, to the initial (zero-based) index of elements in the row.

**factors:** Object of class `"list"` - a list of factorizations of the matrix.

**x:** Object of class `"numeric"` - the non-zero elements of the matrix.

**Dim:** Object of class `"integer"` - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

**Dimnames:** List of length two, see [Matrix](#).

**Extends**

Classes [dsparseMatrix](#), [symmetricMatrix](#), and [RsparseMatrix](#), directly.

Class `"dMatrix"`, by class `"dsparseMatrix"`; class `"sparseMatrix"`, by classes `"dsparseMatrix"` and `"RsparseMatrix"`.

**Methods**

**forceSymmetric** signature (`x = "dsRMatrix"`, `uplo = "missing"`): a trivial method just returning `x`

**forceSymmetric** signature (`x = "dsRMatrix"`, `uplo = "character"`): if `uplo == x@uplo`, this trivially returns `x`; otherwise `t(x)`.

**See Also**

the classes [dgCMatrix](#), [dgTMatrix](#), and [dgeMatrix](#).

## Examples

```
(m0 <- new("dsRMatrix"))
m2 <- new("dsRMatrix", Dim = c(2L,2L),
          x = c(3,1), j = c(1L,1L), p = 0:2)
m2
stopifnot(colSums(as(m2, "TsparseMatrix")) == 3:4)
str(m2)
(ds2 <- forceSymmetric(diag(2))) # dsy*
dR <- as(ds2, "RsparseMatrix")
dR # dsRMatrix
```

---

|                 |  |
|-----------------|--|
| dsyMatrix-class | <i>Symmetric Dense (Packed or Unpacked) Numeric Matrices</i> |
|-----------------|--|

---

## Description

- The "dsyMatrix" class is the class of symmetric, dense matrices in *non-packed* storage and
- "dspMatrix" is the class of symmetric dense matrices in *packed* storage, see [pack\(\)](#). Only the upper triangle or the lower triangle is stored.

## Objects from the Class

Objects can be created by calls of the form `new("dsyMatrix", ...)` or `new("dspMatrix", ...)`, respectively.

## Slots

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**x:** Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order.

**Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#).

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

## Extends

"dsyMatrix" extends class "dgeMatrix", directly, whereas  
 "dspMatrix" extends class "ddenseMatrix", directly.

Both extend class "symmetricMatrix", directly, and class "Matrix" and others, *indirectly*, use [showClass\("dsyMatrix"\)](#), e.g., for details.

## Methods

**norm** signature(x = "dspMatrix", type = "character"), or x = "dsyMatrix" or type = "missing": Computes the matrix norm of the desired type, see, [norm](#).

**rcond** signature(x = "dspMatrix", type = "character"), or x = "dsyMatrix" or type = "missing": Computes the reciprocal condition number, [rcond\(\)](#).

**solve** signature (a = "dspMatrix", b = "..."), and

**solve** signature (a = "dsyMatrix", b = "..."):  $x \leftarrow \text{solve}(a, b)$  solves  $Ax = b$  for  $x$ ; see [solve-methods](#).

**t** signature (x = "dsyMatrix"): Transpose; swaps from upper triangular to lower triangular storage, i.e., the uplo slot from "U" to "L" or vice versa, the same as for all symmetric matrices.

### See Also

Classes [dgeMatrix](#) and [Matrix](#); [solve](#), [norm](#), [rcond](#), [t](#)

### Examples

```
## Only upper triangular part matters (when uplo == "U" as per default)
(sy2 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, NA, 32, 77)))
str(t(sy2)) # uplo = "L", and the lower tri. (i.e. NA is replaced).

chol(sy2) #-> "Cholesky" matrix
(sp2 <- pack(sy2)) # a "dspMatrix"

## Coercing to dpoMatrix gives invalid object:
sy3 <- new("dsyMatrix", Dim = as.integer(c(2,2)), x = c(14, -1, 2, -7))
try(as(sy3, "dpoMatrix")) # -> error: not positive definite

## 4x4 example
m <- matrix(0,4,4); m[upper.tri(m)] <- 1:6
(sym <- m+t(m)+diag(11:14, 4))
(S1 <- pack(sym))
(S2 <- t(S1))
stopifnot(all(S1 == S2)) # equal "seen as matrix", but differ internally :
str(S1)
S2@x
```

---

dtCMatrix-class

*Triangular, (compressed) sparse column matrices*

---

### Description

The "dtCMatrix" class is a class of triangular, sparse matrices in the compressed, column-oriented format. In this implementation the non-zero elements in the columns are sorted into increasing row order.

The "dtTMatrix" class is a class of triangular, sparse matrices in triplet format.

### Objects from the Class

Objects can be created by calls of the form `new("dtCMatrix", ...)` or calls of the form `new("dtTMatrix", ...)`, but more typically automatically via [Matrix\(\)](#) or coercions such as `as(x, "triangularMatrix")`.

## Slots

- uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see [triangularMatrix](#).
- p:** (only present in "dtCMatrix":) an [integer](#) vector for providing pointers, one for each column, see the detailed description in [CsparseMatrix](#).
- i:** Object of class "integer" of length nnzero (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.
- j:** Object of class "integer" of length nnzero (number of non-zero elements). These are the column numbers for each non-zero element in the matrix. (Only present in the [dtTMatrix](#) class.)
- x:** Object of class "numeric" - the non-zero elements of the matrix.
- Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the [Matrix](#), see there.

## Extends

Class "dgCMatrix", directly. Class "triangularMatrix", directly. Class "dMatrix", "sparseMatrix", and more by class "dgCMatrix" etc, see the examples.

## Methods

- solve** signature(a = "dtCMatrix", b = "..."): sparse triangular solve (aka "back-solve" or "forwardsolve"), see [solve-methods](#).
- t** signature(x = "dtCMatrix"): returns the transpose of x
- t** signature(x = "dtTMatrix"): returns the transpose of x

## See Also

Classes [dgCMatrix](#), [dgTMatrix](#), [dgeMatrix](#), and [dtrMatrix](#).

## Examples

```
showClass("dtCMatrix")
showClass("dtTMatrix")
t1 <- new("dtTMatrix", x= c(3,7), i= 0:1, j=3:2, Dim= as.integer(c(4,4)))
t1
## from 0-diagonal to unit-diagonal {low-level step}:
tu <- t1 ; tu@diag <- "U"
tu
(cu <- as(tu, "CsparseMatrix"))
str(cu)# only two entries in @i and @x
stopifnot(cu@i == 1:0,
           all(2 * symmpart(cu) == Diagonal(4) + forceSymmetric(cu)))

t1[1,2:3] <- -1:-2
diag(t1) <- 10*c(1:2,3:2)
t1 # still triangular
(it1 <- solve(t1))
t1. <- solve(it1)
all(abs(t1 - t1.) < 10 * .Machine$double.eps)
```

```
## 2nd example
U5 <- new("dtCMatrix", i= c(1L, 0:3), p=c(0L,0L,0:2, 5L), Dim = c(5L, 5L),
          x = rep(1, 5), diag = "U")
U5
(iu <- solve(U5)) # contains one '0'
validObject(iu2 <- solve(U5, Diagonal(5)))# failed in earlier versions

I5 <- iu %**% U5 # should equal the identity matrix
i5 <- iu2 %**% U5
m53 <- matrix(1:15, 5,3, dimnames=list(NULL,letters[1:3]))
asDiag <- function(M) as(drop0(M), "diagonalMatrix")
stopifnot(
  all.equal(Diagonal(5), asDiag(I5), tolerance=1e-14) ,
  all.equal(Diagonal(5), asDiag(i5), tolerance=1e-14) ,
  identical(list(NULL, dimnames(m53)[[2]]), dimnames(solve(U5, m53)))
)
```

---

|                 |   |
|-----------------|---|
| dtpMatrix-class | <i>Packed Triangular Dense Matrices - "dtpMatrix"</i> |
|-----------------|---|

---

## Description

The "dtpMatrix" class is the class of triangular, dense, numeric matrices in packed storage. The "dtrMatrix" class is the same except in nonpacked storage.

## Objects from the Class

Objects can be created by calls of the form `new("dtpMatrix", ...)` or by coercion from other classes of matrices.

## Slots

- uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see [triangularMatrix](#).
- x:** Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order. For a packed square matrix of dimension  $d \times d$ , `length(x)` is of length  $d(d+1)/2$  (also when `diag == "U"`!).
- Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the [Matrix](#), see there.

## Extends

Class "ddenseMatrix", directly. Class "triangularMatrix", directly. Class "dMatrix" and more by class "ddenseMatrix" etc, see the examples.

## Methods

**%%** signature(x = "dtpMatrix", y = "dgeMatrix"): Matrix multiplication; ditto for several other signature combinations, see `showMethods("%%", class = "dtpMatrix")`.

**determinant** signature(x = "dtpMatrix", logarithm = "logical"): the `determinant`(x) trivially is `prod(diag(x))`, but computed on log scale to prevent over- and underflow.

**diag** signature(x = "dtpMatrix"): ...

**norm** signature(x = "dtpMatrix", type = "character"): ...

**rcond** signature(x = "dtpMatrix", norm = "character"): ...

**solve** signature(a = "dtpMatrix", b = "..."): efficiently using internal backsolve or forwardsolve, see [solve-methods](#).

**t** signature(x = "dtpMatrix"): `t(x)` remains a "dtpMatrix", lower triangular if x is upper triangular, and vice versa.

## See Also

Class [dtrMatrix](#)

```
showClass("dtrMatrix")

example("dtrMatrix-class", echo=FALSE)
(p1 <- pack(T2))
str(p1)
(pp <- pack(T))
ip1 <- solve(p1)
stopifnot(length(p1@x) == 3, length(pp@x) == 3,
           p1 @ uplo == T2 @ uplo, pp @ uplo == T @ uplo,
           identical(t(pp), p1), identical(t(p1), pp),
           all((l.d <- p1 - T2) == 0), is(l.d, "dtpMatrix"),
           all((u.d <- pp - T) == 0), is(u.d, "dtpMatrix"),
           l.d@uplo == T2@uplo, u.d@uplo == T@uplo,
           identical(t(ip1), solve(pp)), is(ip1, "dtpMatrix"),
           all.equal(as(solve(p1,p1), "diagonalMatrix"), Diagonal(2)))
```

---

dtRMatrix-class

*Triangular Sparse Compressed Row Matrices*

---

## Description

The `dtRMatrix` class is a class of triangular, sparse matrices in the compressed, row-oriented format. In this implementation the non-zero elements in the rows are sorted into increasing columnnd order.

## Objects from the Class

This class is currently still mostly unimplemented!

Objects can be created by calls of the form `new("dtRMatrix", ...)`.

**Slots**

- uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular. At present only the lower triangle form is allowed.
- diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see [triangularMatrix](#).
- j:** Object of class "integer" of length `nnzero(.)` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.
- p:** Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row. (Only present in the `dsRMatrix` class.)
- x:** Object of class "numeric" - the non-zero elements of the matrix.
- Dim:** The dimension (a length-2 "integer")
- Dimnames:** corresponding names (or NULL), inherited from the [Matrix](#), see there.

**Extends**

Class "dgRMatrix", directly. Class "dsparseMatrix", by class "dgRMatrix". Class "dMatrix", by class "dgRMatrix". Class "sparseMatrix", by class "dgRMatrix". Class "Matrix", by class "dgRMatrix".

**Methods**

No methods currently with class "dsRMatrix" in the signature.

**See Also**

Classes [dgCMatrix](#), [dgTMatrix](#), [dgeMatrix](#)

**Examples**

```
(m0 <- new("dtRMatrix"))
(m2 <- new("dtRMatrix", Dim = c(2L,2L),
          x = c(5, 1:2), p = c(0L,2:3), j= c(0:1,1L)))
str(m2)
(m3 <- as(Diagonal(2), "RsparseMatrix"))# --> dtRMatrix
```

---

|                 |  |
|-----------------|--|
| dtrMatrix-class | <i>Triangular, dense, numeric matrices</i> |
|-----------------|--|

---

**Description**

The "dtrMatrix" class is the class of triangular, dense, numeric matrices in nonpacked storage. The "dtpMatrix" class is the same except in packed storage, see [pack\(\)](#).

**Objects from the Class**

Objects can be created by calls of the form `new("dtrMatrix", ...)`.

**Slots**

- uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see [triangularMatrix](#).
- x:** Object of class "numeric". The numeric values that constitute the matrix, stored in column-major order.
- Dim:** Object of class "integer". The dimensions of the matrix which must be a two-element vector of non-negative integers.

**Extends**

Class "ddenseMatrix", directly. Class "triangularMatrix", directly. Class "Matrix" and others, by class "ddenseMatrix".

**Methods**

Among others (such as matrix products, e.g. [?crossprod-methods](#)),

**norm** signature(x = "dtrMatrix", type = "character"):..

**rcond** signature(x = "dtrMatrix", norm = "character"):..

**solve** signature(a = "dtrMatrix", b = "..."): efficiently use a "forwardsolve" or backsolve for a lower or upper triangular matrix, respectively, see also [solve-methods](#).

**+, -, \*, ..., ==, >=, ...** all the [Ops](#) group methods are available. When applied to two triangular matrices, these return a triangular matrix when easily possible.

**See Also**

Classes [ddenseMatrix](#), [dtpMatrix](#), [triangularMatrix](#)

**Examples**

```
(m <- rbind(2:3, 0:-1))
(M <- as(m, "generalMatrix"))

(T <- as(M, "triangularMatrix")) # formally upper triangular
(T2 <- as(t(M), "triangularMatrix"))
stopifnot(T@uplo == "U", T2@uplo == "L", identical(T2, t(T)))

m <- matrix(0,4,4); m[upper.tri(m)] <- 1:6
(t1 <- Matrix(m+diag(,4)))
str(t1p <- pack(t1))
(t1pu <- diagN2U(t1p))
stopifnot(exprs = {
  inherits(t1, "dtrMatrix"); validObject(t1)
  inherits(t1p, "dtpMatrix"); validObject(t1p)
  inherits(t1pu, "dtCMatrix"); validObject(t1pu)
  t1pu@x == 1:6
  all(t1pu == t1p)
  identical((t1pu - t1)@x, numeric())# sparse all-0
})
```

## Description

`expand1` and `expand2` construct matrix factors from objects specifying matrix factorizations. Such objects typically do not store the factors explicitly, employing instead a compact representation to save memory.

## Usage

```
expand1(x, which, ...)
expand2(x, ...)

expand(x, ...)
```

## Arguments

|                    |   |
|--------------------|---|
| <code>x</code>     | a matrix factorization, typically inheriting from virtual class <a href="#">MatrixFactorization</a> . |
| <code>which</code> | a character string indicating a matrix factor.  |
| <code>...</code>   | further arguments passed to or from methods.  |

## Details

Methods for `expand` are retained only for backwards compatibility with **Matrix** < 1.6-0. New code should use `expand1` and `expand2`, whose methods provide more control and behave more consistently. Notably, `expand2` obeys the rule that the product of the matrix factors in the returned list should reproduce (within some tolerance) the factorized matrix, *including* its `dimnames`.

Hence if `x` is a matrix and `y` is its factorization, then

```
all.equal(as(x, "matrix"), as(Reduce(`%*%`, expand2(y)), "matrix"))
```

should in most cases return `TRUE`.

## Value

`expand1` returns an object inheriting from virtual class [Matrix](#), representing the factor indicated by `which`, always without row and column names.

`expand2` returns a list of factors, typically with names using conventional notation, as in `list(L=, U=)`. The first and last factors get the row and column names of the factorized matrix, which are preserved in the `Dimnames` slot of `x`.

## Methods

The following table lists methods for `expand1` together with allowed values of argument `which`.

|                          |  |
|--------------------------|--|
| <code>class(x)</code>    | <code>which</code>                                 |
| <a href="#">Schur</a>    | <code>c("Q", "T", "Q.")</code>                     |
| <a href="#">denseLU</a>  | <code>c("P1", "P1.", "L", "U")</code>              |
| <a href="#">sparseLU</a> | <code>c("P1", "P1.", "P2", "P2.", "L", "U")</code> |

```

sparseQR      c("P1", "P1.", "P2", "P2.", "Q", "Q1", "R", "R1")
BunchKaufman, pBunchKaufman c("U", "DU", "U.", "L", "DL", "L.")
Cholesky, pCholesky       c("P1", "P1.", "L1", "D", "L1.", "L", "L.")
CHMsimpl, CHMsimpl       c("P1", "P1.", "L1", "D", "L1.", "L", "L.")

```

Methods for `expand2` and `expand` are described below. Factor names and classes apply also to `expand1`.

`expand2 signature(x = "CHMsimpl")`: expands the factorization  $A = P_1' L_1 D L_1' P_1 = P_1' L L' P_1$  as `list(P1., L1, D, L1., P1)` (the default) or as `list(P1., L, L., P1)`, depending on optional logical argument `LDL`. `P1` and `P1.` are `pMatrix`, `L1`, `L1.`, `L`, and `L.` are `dtCMatrix`, and `D` is a `ddiMatrix`.

`expand2 signature(x = "CHMsupper")`: as `CHMsimpl`, but the triangular factors are stored as `dgCMatrix`.

`expand2 signature(x = "p?Cholesky")`: expands the factorization  $A = L_1 D L_1' = L L'$  as `list(L1, D, L1.)` (the default) or as `list(L, L.)`, depending on optional logical argument `LDL`. `L1`, `L1.`, `L`, and `L.` are `dtrMatrix` or `dtpMatrix`, and `D` is a `ddiMatrix`.

`expand2 signature(x = "p?BunchKaufman")`: expands the factorization  $A = U D_U U' = L D_L L'$  where  $U = \prod_{k=1}^{b_U} P_k U_k$  and  $L = \prod_{k=1}^{b_L} P_k L_k$  as `list(U, DU, U.)` or `list(L, DL, L.)`, depending on `x@uplo`. If optional argument `complete` is `TRUE`, then an unnamed list giving the full expansion with  $2b_U + 1$  or  $2b_L + 1$  matrix factors is returned instead.  $P_k$  are represented as `pMatrix`,  $U_k$  and  $L_k$  are represented as `dtCMatrix`, and  $D_U$  and  $D_L$  are represented as `dsCMatrix`.

`expand2 signature(x = "Schur")`: expands the factorization  $A = Q T Q'$  as `list(Q, T, Q.)`. `Q` and `Q.` are `x@Q` and `t(x@Q)` modulo `Dimnames`, and `T` is `x@T`.

`expand2 signature(x = "sparseLU")`: expands the factorization  $A = P_1' L U P_2'$  as `list(P1., L, U, P2.)`. `P1.` and `P2.` are `pMatrix`, and `L` and `U` are `dtCMatrix`.

`expand2 signature(x = "denseLU")`: expands the factorization  $A = P_1' L U$  as `list(P1., L, U)`. `P1.` is a `pMatrix`, and `L` and `U` are `dtrMatrix` if square and `dgeMatrix` otherwise.

`expand2 signature(x = "sparseQR")`: expands the factorization  $A = P_1' Q R P_2' = P_1' Q_1 R_1 P_2'$  as `list(P1., Q, R, P2.)` or `list(P1., Q1, R1, P2.)`, depending on optional logical argument `complete`. `P1.` and `P2.` are `pMatrix`, `Q` and `Q1` are `dgeMatrix`, `R` is a `dgCMatrix`, and `R1` is a `dtCMatrix`.

`expand signature(x = "CHMfactor")`: as `expand2`, but returning `list(P, L)`. `expand(x)[["P"]]` and `expand2(x)[["P1"]]` represent the same permutation matrix  $P_1$  but have opposite margin slots and inverted perm slots. The components of `expand(x)` do not preserve `x@Dimnames`.

`expand signature(x = "sparseLU")`: as `expand2`, but returning `list(P, L, U, Q)`. `expand(x)[["Q"]]` and `expand2(x)[["P2."]]` represent the same permutation matrix  $P_2'$  but have opposite margin slots and inverted perm slots. `expand(x)[["P"]]` represents the permutation matrix  $P_1$  rather than its transpose  $P_1'$ ; it is `expand2(x)[["P1.")] with an inverted perm slot. expand(x)[["L"]] and expand2(x)[["L"]] represent the same unit lower triangular matrix  $L$ , but with diag slot equal to "N" and "U", respectively. expand(x)[["L"]] and expand(x)[["U"]] store the permuted first and second components of x@Dimnames in their Dimnames slots.`

`expand signature(x = "denseLU")`: as `expand2`, but returning `list(L, U, P)`. `expand(x)[["P"]]` and `expand2(x)[["P1.")] are identical modulo Dimnames. The components of expand(x) do not preserve x@Dimnames.`

The virtual class [MatrixFactorization](#) of matrix factorizations.

Generic functions [Cholesky](#), [BunchKaufman](#), [Schur](#), [lu](#), and [qr](#) for *computing* factorizations.

**Examples**

```
showMethods("expand1", inherited = FALSE)
showMethods("expand2", inherited = FALSE)
set.seed(0)

(A <- Matrix(rnorm(9L, 0, 10), 3L, 3L))
(lu.A <- lu(A))
(e.lu.A <- expand2(lu.A))
stopifnot(exprs = {
  is.list(e.lu.A)
  identical(names(e.lu.A), c("P1.", "L", "U"))
  all(sapply(e.lu.A, is, "Matrix"))
  all.equal(as(A, "matrix"), as(Reduce(`%*%`, e.lu.A), "matrix"))
})

## 'expand1' and 'expand2' give equivalent results modulo
## dimnames and representation of permutation matrices;
## see also function 'alt' in example("Cholesky-methods")
(al <- sapply(names(e.lu.A), expand1, x = lu.A, simplify = FALSE))
all.equal(al, e.lu.A)

## see help("denseLU-class") and others for more examples
```

expm-methods

*Matrix Exponential***Description**

Compute the exponential of a matrix.

**Usage**

```
expm(x)
```

**Arguments**

**x** a matrix, typically inheriting from the [dMatrix](#) class.

**Details**

The exponential of a matrix is defined as the infinite Taylor series  $\expm(A) = I + A + A^2/2! + A^3/3! + \dots$  (although this is definitely not the way to compute it). The method for the `dgeMatrix` class uses Ward's diagonal Pade' approximation with three step preconditioning, a recommendation from Moler & Van Loan (1978) "Nineteen dubious ways...".

**Value**

The matrix exponential of  $x$ .

**Author(s)**

This is a translation of the implementation of the corresponding Octave function contributed to the Octave project by A. Scottedward Hodel <A.S.Hodel@Eng.Auburn.EDU>. A bug in there has been fixed by Martin Maechler.

**References**

Cleve Moler and Charles Van Loan (2003) Nineteen dubious ways to compute the exponential of a matrix, twenty-five years later. *SIAM Review* **45**, 1, 3–49. doi:10.1137/S00361445024180

for historical reference mostly:

Moler, C. and Van Loan, C. (1978) Nineteen dubious ways to compute the exponential of a matrix. *SIAM Review* **20**, 4, 801–836. doi:10.1137/1020098

Eric W. Weisstein et al. (1999) *Matrix Exponential*. From MathWorld, <https://mathworld.wolfram.com/MatrixExponential.html>

**See Also**

Package **expm**, which provides newer (in some cases faster, more accurate) algorithms for computing the matrix exponential via its own (non-generic) function `expm()`. **expm** also implements `logm()`, `sqrtn()`, etc.

Generic function [Schur](#).

**Examples**

```
(m1 <- Matrix(c(1,0,1,1), ncol = 2))
(e1 <- expm(m1)) ; e <- exp(1)
stopifnot(all.equal(e1@x, c(e,0,e,e), tolerance = 1e-15))
(m2 <- Matrix(c(-49, -64, 24, 31), ncol = 2))
(e2 <- expm(m2))
(m3 <- Matrix(cbind(0, rbind(6*diag(3), 0)))) # sparse!
(e3 <- expm(m3)) # upper triangular
```

---

externalFormats

Read and write external matrix formats

---

**Description**

Read matrices stored in the Harwell-Boeing or MatrixMarket formats or write `sparseMatrix` objects to one of these formats.

**Usage**

```
readHB(file)
readMM(file)
writeMM(obj, file, ...)
```

**Arguments**

`obj` a real sparse matrix

`file` for `writeMM` - the name of the file to be written. For `readHB` and `readMM` the name of the file to read, as a character scalar. The names of files storing matrices in the Harwell-Boeing format usually end in `".rua"` or `".rsa"`. Those storing matrices in the MatrixMarket format usually end in `".mtx"`. Alternatively, `readHB` and `readMM` accept connection objects.

`...` optional additional arguments. Currently none are used in any methods.

**Value**

The `readHB` and `readMM` functions return an object that inherits from the `"Matrix"` class. Methods for the `writeMM` generic functions usually return `NULL` and, as a side effect, the matrix `obj` is written to `file` in the MatrixMarket format (`writeMM`).

**Note**

The Harwell-Boeing format is older and less flexible than the MatrixMarket format. The function `writeHB` was deprecated and has now been removed. Please use `writeMM` instead.

Note that these formats do *not* know anything about `dimnames`, hence these are dropped by `writeMM()`.

A very simple way to export small sparse matrices `S`, is to use `summary(S)` which returns a `data.frame` with columns `i`, `j`, and possibly `x`, see `summary` in `sparseMatrix-class`, and an example below.

**References**

<https://math.nist.gov/MatrixMarket/>  
<https://sparse.tamu.edu/>

**Examples**

```
str(pores <- readMM(system.file("external/pores_1.mtx", package = "Matrix")))
str(utm <- readHB(system.file("external/utm300.rua" , package = "Matrix")))
str(lundA <- readMM(system.file("external/lund_a.mtx" , package = "Matrix")))
str(lundA <- readHB(system.file("external/lund_a.rsa" , package = "Matrix")))
## https://math.nist.gov/MatrixMarket/data/Harwell-Boeing/counterx/counterx.htm
str(jgl <- readMM(system.file("external/jgl009.mtx" , package = "Matrix")))

## NOTE: The following examples take quite some time
## ---- even on a fast internet connection:
if(FALSE) {
  ## The URL has been corrected, but we need an untar step:
  u. <- url("https://www.cise.ufl.edu/research/sparse/RB/Boeing/msc00726.tar.gz")
  str(sm <- readHB(gzcon(u.)))
}

data(KNex, package = "Matrix")
## Store as MatrixMarket (".mtx") file, here inside temporary dir./folder:
(MMfile <- file.path(tempdir(), "mmMM.mtx"))
writeMM(KNex$mm, file=MMfile)
file.info(MMfile)[,c("size", "ctime")] # (some confirmation of the file's)
```

```
## very simple export - in triplet format - to text file:
data(CAex, package = "Matrix")
s.CA <- summary(CAex)
s.CA # shows (i, j, x) [columns of a data frame]
message("writing to ", outf <- tempfile())
write.table(s.CA, file = outf, row.names=FALSE)
## and read it back -- showing off sparseMatrix():
str(dd <- read.table(outf, header=TRUE))
## has columns (i, j, x) -> we can use via do.call() as arguments to sparseMatrix():
mm <- do.call(sparseMatrix, dd)
stopifnot(all.equal(mm, CAex, tolerance=1e-15))
```

---

facmul-methods

---

*Multiplication by Factors from Matrix Factorizations*

---

## Description

Multiplies a matrix or vector on the left or right by a factor from a matrix factorization or its transpose.

## Usage

```
facmul(x, factor, y, trans = FALSE, left = TRUE, ...)
```

## Arguments

|                     |   |
|---------------------|---|
| <code>x</code>      | a <a href="#">MatrixFactorization</a> object.   |
| <code>factor</code> | a character string indicating a factor in the factorization represented by <code>x</code> , typically an element of <code>names(expand2(x, ...))</code> . |
| <code>y</code>      | a matrix or vector to be multiplied on the left or right by the factor or its transpose.  |
| <code>trans</code>  | a logical indicating if the transpose of the factor should be used, rather than the factor itself.  |
| <code>left</code>   | a logical indicating if the <code>y</code> should be multiplied on the left by the factor, rather than on the right.                                      |
| <code>...</code>    | further arguments passed to or from methods.  |

## Details

`facmul` is experimental and currently no methods are exported from **Matrix**.

## Value

The value of `op(M) %*% y` or `y %*% op(M)`, depending on `left`, where `M` is the factor (always *without* `dimnames`) and `op(M)` is `M` or `t(M)`, depending on `trans`.

## Examples

```
## Conceptually, methods for 'facmul' _would_ behave as follows ...
## Not run:
n <- 3L
x <- lu(Matrix(rnorm(n * n), n, n))
y <- rnorm(n)
L <- unname(expand2(x)[[nm <- "L"]])
stopifnot(exprs = {
  all.equal(facmul(x, nm, y, trans = FALSE, left = TRUE), L %**% y)
  all.equal(facmul(x, nm, y, trans = FALSE, left = FALSE), y %**% L)
  all.equal(facmul(x, nm, y, trans = TRUE, left = TRUE), crossprod(L, y))
  all.equal(facmul(x, nm, y, trans = TRUE, left = FALSE), tcrossprod(y, L))
})

## End(Not run)
```

---

fastMisc

*“Low Level” Coercions and Methods*

---

## Description

“Semi-API” functions used internally by **Matrix**, often to bypass S4 dispatch and avoid the associated overhead. These are exported to provide this capability to expert users. Typical users should continue to rely on S4 generic functions to dispatch suitable methods, by calling, e.g., `as(., <class>)` for coercions.

## Usage

```
.M2kind(from, kind = ".", sparse = NA)

.M2gen(from, kind = ".")
.M2sym(from, ...)
.M2tri(from, ...)
.M2diag(from)

.M2v(from)
.M2m(from)
.M2unpacked(from)
.M2packed(from)
.M2C(from)
.M2R(from)
.M2T(from)

.M2V(from)
.m2V(from, kind = ".")

.sparse2dense(from, packed = FALSE)
.diag2dense(from, kind = ".", shape = "t", packed = FALSE, uplo = "U")
.ind2dense(from, kind = "n")
.m2dense(from, class = ".ge", uplo = "U", diag = "N", trans = FALSE)

.dense2sparse(from, repr = "C")
```

```

.diag2sparse(from, kind = ".", shape = "t", repr = "C", uplo = "U")
.ind2sparse(from, kind = "n", repr = ".")
.m2sparse(from, class = ".gC", uplo = "U", diag = "N", trans = FALSE)

.tCRT(x, lazy = TRUE)

.diag.dsC(x, Chx = Cholesky(x, LDL = TRUE), res.kind = "diag")

.solve.dgC.lu (a, b, tol = .Machine$double.eps, check = TRUE)
.solve.dgC.qr (a, b, order = 3L, check = TRUE)
.solve.dgC.chol(a, b, check = TRUE)

.updateCHMfactor(object, parent, mult = 0)

```

### Arguments

|               |   |
|---------------|---|
| from, x, a, b | a <a href="#">Matrix</a> , matrix, or vector.   |
| kind          | a string (".", "r", "n", "l", or "d") specifying the “kind” of the result. "." indicates that the kind of from should be preserved. "r" is equivalent to "z" if from is complex and to "d" otherwise. "n" indicates that the result should inherit from <a href="#">nMatrix</a> or <a href="#">nsparseVector</a> (and so on). |
| shape         | a string (".", "g", "s", or "t") specifying the “shape” of the result. "." indicates that the shape of from should be preserved. "g" indicates that the result should inherit from <a href="#">generalMatrix</a> (and so on).   |
| repr          | a string (".", "C", "R", or "T") specifying the sparse representation of the result. "." is accepted only by .ind2sparse and indicates the most efficient representation, which is "C" ("R") for margin = 2 (1). "C" indicates that the result should inherit from <a href="#">CsparseMatrix</a> (and so on).                 |
| packed        | a logical indicating if the result should inherit from <a href="#">packedMatrix</a> rather than from <a href="#">unpackedMatrix</a> . It is ignored for from inheriting from <a href="#">generalMatrix</a> .  |
| sparse        | a logical indicating if the result should inherit from <a href="#">sparseMatrix</a> rather than from <a href="#">denseMatrix</a> . If NA, then the result will be formally sparse if and only if from is.   |
| uplo          | a string ("U" or "L") indicating whether the result (if symmetric or triangular) should store the upper or lower triangle of from. The elements of from in the opposite triangle are ignored.   |
| diag          | a string ("N" or "U") indicating whether the result (if triangular) should be formally nonunit or unit triangular. In the unit triangular case, the diagonal elements of from are ignored.  |
| trans         | a logical indicating if the result should be a 1-row matrix rather than a 1-column matrix where from is a vector but not a matrix.  |
| class         | a string whose first three characters specify the class of the result. It should match the pattern <code>"^[.nld](ge sy tr sp tp)"</code> for .m2dense and <code>"^[.nld][gst][CRT]"</code> for .m2sparse, where "." in the first position is equivalent to "l" for logical arguments and "d" for numeric arguments.          |
| ...           | optional arguments passed to <a href="#">isSymmetric</a> or <a href="#">isTriangular</a> .  |
| lazy          | a logical indicating if the transpose should be constructed with minimal allocation, but possibly <i>without</i> preserving representation.   |

|          |  |
|----------|--|
| Chx      | optionally, the <code>Cholesky(x, ...)</code> factorization of <code>x</code> . If supplied, then <code>x</code> is unused.  |
| res.kind | a string in <code>c("trace", "sumLog", "prod", "min", "max", "range", "diag", "diagBack")</code> .   |
| tol      | see <code>lu-methods</code> .  |
| order    | see <code>qr-methods</code> .  |
| check    | a logical indicating if the first argument should be tested for inheritance from <code>dgCMatrix</code> and coerced if necessary. Set to <code>FALSE</code> for speed only if it is known to already inherit from <code>dgCMatrix</code> . |
| object   | a Cholesky factorization inheriting from virtual class <code>CHMfactor</code> , almost always the result of a call to generic function <code>Cholesky</code> .   |
| parent   | an object of class <code>dsCMatrix</code> or class <code>dgCMatrix</code> .  |
| mult     | a numeric vector of positive length. Only the first element is used, and that must be finite.  |

## Details

Functions with names of the form `.<A>2<B>` implement coercions from virtual class A to the “nearest” non-virtual subclass of virtual class B, where the virtual classes are abbreviated as follows:

M `Matrix`  
V `sparseVector`  
m `matrix`  
v `vector`  
dense `denseMatrix`  
unpacked `unpackedMatrix`  
packed `packedMatrix`  
sparse `CsparseMatrix`, `RsparseMatrix`, or `TsparseMatrix`  
C `CsparseMatrix`  
R `RsparseMatrix`  
T `TsparseMatrix`  
gen `generalMatrix`  
sym `symmetricMatrix`  
tri `triangularMatrix`  
diag `diagonalMatrix`  
ind `indMatrix`

Abbreviations should be seen as a guide, rather than as an exact description of behaviour. Notably, `.m2dense`, `.m2sparse`, and `.m2V` accept vectors that are not matrices.

`.tCRT(x)`: If `lazy = TRUE`, then `.tCRT` constructs the transpose of `x` using the most efficient representation, which for ‘CRT’ is ‘RCT’. If `lazy = FALSE`, then `.tCRT` preserves the representation of `x`, behaving as the corresponding methods for generic function `t`.

`.diag.dsC(x)`: `.diag.dsC` computes (or uses if `Chx` is supplied) the Cholesky factorization of `x` as *LDL'* in order to calculate one of several possible statistics from the diagonal entries of *D*. See `res.kind` under ‘Arguments’.

`.solve.dgC.*(a, b):` `.solve.dgC.lu(a, b)` needs a square matrix `a`.  
`.solve.dgC.qr(a, b)` needs a “long” matrix `a`, with `nrow(a) >= ncol(a)`.  
`.solve.dgC.chol(a, b)` needs a “wide” matrix `a`, with `nrow(a) <= ncol(a)`.

All three may be used to solve sparse linear systems directly. Only `.solve.dgC.qr` and `.solve.dgC.chol` be used to solve sparse *least squares* problems.

`.updateCHMfactor(object, parent, mult):` `.updateCHMfactor` updates `object` with the result of Cholesky factorizing `F(parent) + mult[1] * diag(nrow(parent))`, i.e., `F(parent)` plus `mult[1]` times the identity matrix, where `F = identity` if `parent` is a `dsCMatrix` and `F = tcrossprod` if `parent` is a `dgCMatrix`. The nonzero pattern of `F(parent)` must match that of `S` if `object = Cholesky(S, ...)`.

## Examples

```
D. <- diag(x = c(1, 1, 2, 3, 5, 8))
D.0 <- Diagonal(x = c(0, 0, 0, 3, 5, 8))
S. <- toeplitz(as.double(1:6))
C. <- new("dgCMatrix", Dim = c(3L, 4L),
          p = c(0L, 1L, 1L, 1L, 3L), i = c(1L, 0L, 2L), x = c(-8, 2, 3))

stopifnot(exprs = {
  identical(.M2tri(D.), as(D., "triangularMatrix"))
  identical(.M2sym(D.), as(D., "symmetricMatrix"))
  identical(.M2diag(D.), as(D., "diagonalMatrix"))
  identical(.M2kind(C., "l"),
            as(C., "lMatrix"))
  identical(.M2kind(.sparse2dense(C.), "l"),
            as(as(C., "denseMatrix"), "lMatrix"))
  identical(.diag2sparse(D.0, ".", "t", "C"),
            .dense2sparse(.diag2dense(D.0, ".", "t", TRUE), "C"))
  identical(.M2gen(.diag2dense(D.0, ".", "s", FALSE)),
            .sparse2dense(.M2gen(.diag2sparse(D.0, ".", "s", "T"))))
  identical(S.,
            .M2m(.m2sparse(S., ".sR")))
  identical(S. * lower.tri(S.) + diag(1, 6L),
            .M2m(.m2dense(S., ".tr", "L", "U")))
  identical(.M2R(C.), .M2R(.M2T(C.)))
  identical(.tCRT(C.), .M2R(t(C.)))
})

A <- tcrossprod(C.)/6 + Diagonal(3, 1/3); A[1,2] <- 3; A
stopifnot(exprs = {
  is.numeric(x. <- c(2.2, 0, -1.2) )
  all.equal(x., .solve.dgC.lu(A, c(1,0,0), check=FALSE))
  all.equal(x., .solve.dgC.qr(A, c(1,0,0), check=FALSE))
})

## Solving sparse least squares:

X <- rbind(A, Diagonal(3)) # design matrix X (for L.S.)
Xt <- t(X)                 # *transposed* X (for L.S.)
(y <- drop(crossprod(Xt, 1:3)) + c(-1,1)/1000) # small rand.err.
str(solveCh <- .solve.dgC.chol(Xt, y, check=FALSE)) # Xt *is* dgC..
stopifnot(exprs = {
  all.equal(solveCh$coef, 1:3, tol = 1e-3) # rel.err ~ 1e-4
```

```

all.equal(solveCh$coef, drop(solve(tcrossprod(Xt), Xt %**% y)))
all.equal(solveCh$coef, .solve.dgC.qr(X, y, check=FALSE))
})

```

---

forceSymmetric-methods

*Force a Matrix to 'symmetricMatrix' Without Symmetry Checks*

---

## Description

Force a square matrix `x` to a `symmetricMatrix`, **without** a symmetry check as it would be applied for `as(x, "symmetricMatrix")`.

## Usage

```
forceSymmetric(x, uplo)
```

## Arguments

|                   |  |
|-------------------|--|
| <code>x</code>    | any square matrix (of numbers), either “traditional” ( <code>matrix</code> ) or inheriting from <code>Matrix</code> .  |
| <code>uplo</code> | optional string, "U" or "L" indicating which “triangle” half of <code>x</code> should determine the result. The default is "U" unless <code>x</code> already has a <code>uplo</code> slot (i.e., when it is <code>symmetricMatrix</code> , or <code>triangularMatrix</code> ), where the default will be <code>x@uplo</code> . |

## Value

a square matrix inheriting from class `symmetricMatrix`.

## See Also

`symmpart` for the symmetric part of a matrix, or the coercions `as(x, <symmetricMatrix class>)`.

## Examples

```

## Hilbert matrix
i <- 1:6
h6 <- 1/outer(i - 1L, i, "+")
sd <- sqrt(diag(h6))
hh <- t(h6/sd)/sd # theoretically symmetric
isSymmetric(hh, tol=0) # FALSE; hence
try( as(hh, "symmetricMatrix") ) # fails, but this works fine:
H6 <- forceSymmetric(hh)

## result can be pretty surprising:
(M <- Matrix(1:36, 6))
forceSymmetric(M) # symmetric, hence very different in lower triangle
(tm <- tril(M))
forceSymmetric(tm)

```

## Description

Utilities for formatting sparse numeric matrices in a flexible way. These functions are used by the `format` and `print` methods for sparse matrices and can be applied as well to standard R matrices. Note that *all* arguments but the first are optional.

`formatSparseM()` is the main “workhorse” of `formatSpMatrix`, the `format` method for sparse matrices.

`.formatSparseSimple()` is a simple helper function, also dealing with (short/empty) column names construction.

## Usage

```
formatSparseM(x, zero.print = ".", align = c("fancy", "right"),
              m = as(x, "matrix"), asLogical=NULL, uniDiag=NULL,
              digits=NULL, cx, iN0, dn = dimnames(m))

.formatSparseSimple(m, asLogical=FALSE, digits=NULL,
                   col.names, note.dropping.colnames = TRUE,
                   dn=dimnames(m))
```

## Arguments

|  |   |
|--|---|
| <code>x</code>                                 | an R object inheriting from class <code>sparseMatrix</code> .   |
| <code>zero.print</code>                        | character which should be used for <i>structural</i> zeroes. The default "." may occasionally be replaced by " " (blank); using "0" would look almost like <code>print()</code> ing of non-sparse matrices. |
| <code>align</code>                             | a string specifying how the <code>zero.print</code> codes should be aligned, see <code>formatSpMatrix</code> .  |
| <code>m</code>                                 | (optional) a (standard R) <code>matrix</code> version of <code>x</code> .   |
| <code>asLogical</code>                         | should the matrix be formatted as a logical matrix (or rather as a numeric one); mostly for <code>formatSparseM()</code> .  |
| <code>uniDiag</code>                           | logical indicating if the diagonal entries of a sparse unit triangular or unit-diagonal matrix should be formatted as "I" instead of "1" (to emphasize that the 1's are “structural”).                      |
| <code>digits</code>                            | significant digits to use for printing, see <code>print.default</code> .  |
| <code>cx</code>                                | (optional) character matrix; a formatted version of <code>x</code> , still with strings such as "0.00" for the zeros.   |
| <code>iN0</code>                               | (optional) integer vector, specifying the location of the <i>non</i> -zeroes of <code>x</code> .  |
| <code>col.names, note.dropping.colnames</code> | see <code>formatSpMatrix</code> .   |
| <code>dn</code>                                | <code>dimnames</code> to be used; a list (of length two) with row and column names (or <code>NULL</code> ).   |

**Value**

a character matrix like `cx`, where the zeros have been replaced with (padded versions of) `zero.print`. As this is a *dense* matrix, do not use these functions for really large (really) sparse matrices!

**Author(s)**

Martin Maechler

**See Also**

`formatSpMatrix` which calls `formatSparseM()` and is the `format` method for sparse matrices.

`printSpMatrix` which is used by the (typically implicitly called) `show` and `print` methods for sparse matrices.

**Examples**

```
m <- suppressWarnings(matrix(c(0, 3.2, 0, 0, 11, 0, 0, 0, 0, -7, 0), 4, 9))
fm <- formatSparseM(m)
noquote(fm)
## nice, but this is nicer {with "units" vertically aligned}:
print(fm, quote=FALSE, right=TRUE)
## and "the same" as :
Matrix(m)

## align = "right" is cheaper --> the "." are not aligned:
noquote(f2 <- formatSparseM(m, align="r"))
stopifnot(f2 == fm | m == 0, dim(f2) == dim(m),
          (f2 == ".") == (m == 0))
```

---

generalMatrix-class

*Class "generalMatrix" of General Matrices*

---

**Description**

Virtual class of “general” matrices; i.e., matrices that do not have a known property such as symmetric, triangular, or diagonal.

**Objects from the Class**

A virtual Class: No objects may be created from it.

**Slots**

`Dim`, `Dimnames` inherited from virtual class `Matrix`.

`factors` a list of `MatrixFactorization` objects caching factorizations of the matrix. Typically, it is initialized as an empty list and updated “automagically” whenever a factorization is computed.

**Extends**

Class "Matrix", directly.

**See Also**

Virtual classes [symmetricMatrix](#), [triangularMatrix](#), and [diagonalMatrix](#).

---

Hilbert

*Generate a Hilbert matrix*

---

**Description**

Generate the  $n$  by  $n$  symmetric Hilbert matrix. Because these matrices are ill-conditioned for moderate to large  $n$ , they are often used for testing numerical linear algebra code.

**Usage**

```
Hilbert(n)
```

**Arguments**

$n$  a non-negative integer.

**Value**

the  $n$  by  $n$  symmetric Hilbert matrix as a "dpoMatrix" object.

**See Also**

the class [dpoMatrix](#)

**Examples**

```
Hilbert(6)
```

---

image-methods

*Methods for image() in Package 'Matrix'*

---

**Description**

Methods for function [image](#) in package **Matrix**. An image of a matrix simply color codes all matrix entries and draws the  $n \times m$  matrix using an  $n \times m$  grid of (colored) rectangles.

The **Matrix** package image methods are based on [levelplot\(\)](#) from package **lattice**; hence these methods return an “object” of class "trellis", producing a graphic when (auto-) [print\(\)](#) ed.

## Usage

```
## S4 method for signature 'dgTMatrix'
image(x,
      xlim = c(1, di[2]),
      ylim = c(di[1], 1), aspect = "iso",
      sub = sprintf("Dimensions: %d x %d", di[1], di[2]),
      xlab = "Column", ylab = "Row", cuts = 15,
      useRaster = FALSE,
      useAbs = NULL, colorkey = !useAbs,
      col.regions = NULL,
      lwd = NULL, border.col = NULL, ...)
```

## Arguments

|                              |  |
|------------------------------|--|
| <code>x</code>               | a Matrix object, i.e., fulfilling <code>is(x, "Matrix")</code> .   |
| <code>xlim, ylim</code>      | x- and y-axis limits; may be used to “zoom into” matrix. Note that <i>x, y</i> “feel reversed”: <code>ylim</code> is for the rows (= 1st index) and <code>xlim</code> for the columns (= 2nd index). For convenience, when the limits are integer valued, they are both extended by 0.5; also, <code>ylim</code> is always used decreasingly.  |
| <code>aspect</code>          | aspect ratio specified as number ( <i>y/x</i> ) or string; see <code>levelplot</code> .  |
| <code>sub, xlab, ylab</code> | axis annotation with sensible defaults; see <code>plot.default</code> .  |
| <code>cuts</code>            | number of levels the range of matrix values would be divided into.   |
| <code>useRaster</code>       | logical indicating if raster graphics should be used (instead of the tradition rectangle vector drawing). If true, <code>panel.levelplot.raster</code> (from <b>lattice</b> package) is used, and the colorkey is also done via rasters, see also <code>levelplot</code> and possibly <code>grid.raster</code> .<br><br>Note that using raster graphics may often be faster, but can be slower, depending on the matrix dimensions and the graphics device (dimensions). |
| <code>useAbs</code>          | logical indicating if <code>abs(x)</code> should be shown; if TRUE, the former (implicit) default, the default <code>col.regions</code> will be <code>grey</code> colors (and no colorkey drawn). The default is FALSE unless the matrix has no negative entries.  |
| <code>colorkey</code>        | logical indicating if a color key aka ‘legend’ should be produced. Default is to draw one, unless <code>useAbs</code> is true. You can also specify a <code>list</code> , see <code>levelplot</code> , such as <code>list(raster=TRUE)</code> in the case of rastering.  |
| <code>col.regions</code>     | vector of gradually varying colors; see <code>levelplot</code> .   |
| <code>lwd</code>             | (only used when <code>useRaster</code> is false:) non-negative number or NULL (default), specifying the line-width of the rectangles of each non-zero matrix entry (drawn by <code>grid.rect</code> ). The default depends on the matrix dimension and the device size.  |
| <code>border.col</code>      | color for the border of each rectangle. NA means no border is drawn. When NULL as by default, <code>border.col &lt;- if(lwd &lt; .01) NA else NULL</code> is used. Consider using an opaque color instead of NULL which corresponds to <code>grid::get.gpar("col")</code> .  |
| <code>...</code>             | further arguments passed to methods and <code>levelplot</code> , notably at for specifying (possibly non equidistant) cut values for dividing the matrix values (superseeding <code>cuts</code> above).  |

## Value

as all **lattice** graphics functions, `image(<Matrix>)` returns a "trellis" object, effectively the result of `levelplot()`.

## Methods

All methods currently end up calling the method for the `dgTMatrix` class. Use `showMethods(image)` to list them all.

## See Also

`levelplot`, and `print.trellis` from package **lattice**.

## Examples

```
showMethods(image)
## And if you want to see the method definitions:
showMethods(image, includeDefs = TRUE, inherited = FALSE)

data(CAex, package = "Matrix")
image(CAex, main = "image(CAex)") -> imgC; imgC
stopifnot(!is.null(leg <- imgC$legend), is.list(leg$right)) # failed for 2 days ..
image(CAex, useAbs=TRUE, main = "image(CAex, useAbs=TRUE)")

cCA <- Cholesky(crossprod(CAex), Imult = .01)
## See ?print.trellis --- place two image() plots side by side:
print(image(cCA, main="Cholesky(crossprod(CAex), Imult = .01)",
  split=c(x=1,y=1,nx=2, ny=1), more=TRUE)
print(image(cCA, useAbs=TRUE),
  split=c(x=2,y=1,nx=2,ny=1))

data(USCounties, package = "Matrix")
image(USCounties)# huge
image(sign(USCounties))## just the pattern
  # how the result looks, may depend heavily on
  # the device, screen resolution, antialiasing etc
  # e.g. x11(type="Xlib") may show very differently than cairo-based

## Drawing borders around each rectangle;
  # again, viewing depends very much on the device:
image(USCounties[1:400,1:200], lwd=.1)
## Using (xlim,ylim) has advantage : matrix dimension and (col/row) indices:
image(USCounties, c(1,200), c(1,400), lwd=.1)
image(USCounties, c(1,300), c(1,200), lwd=.5 )
image(USCounties, c(1,300), c(1,200), lwd=.01)
## These 3 are all equivalent :
(I1 <- image(USCounties, c(1,100), c(1,100), useAbs=FALSE))
I2 <- image(USCounties, c(1,100), c(1,100), useAbs=FALSE, border.col=NA)
I3 <- image(USCounties, c(1,100), c(1,100), useAbs=FALSE, lwd=2, border.col=NA)
stopifnot(all.equal(I1, I2, check.environment=FALSE),
  all.equal(I2, I3, check.environment=FALSE))
## using an opaque border color
image(USCounties, c(1,100), c(1,100), useAbs=FALSE, lwd=3, border.col = adjustcolor("skyb

if(interactive() || nzchar(Sys.getenv("R_MATRIX_CHECK_EXTRA"))) {
## Using raster graphics: For PDF this would give a 77 MB file,
```

```
## however, for such a large matrix, this is typically considerably
## *slower* (than vector graphics rectangles) in most cases :
if(doPNG <- !dev.interactive())
  png("image-USCounties-raster.png", width=3200, height=3200)
image(USCounties, useRaster = TRUE) # should not suffer from anti-aliasing
if(doPNG)
  dev.off()
  ## and now look at the *.png image in a viewer you can easily zoom in and out
}#only if(doExtras)
```

index-class

*Virtual Class “index” of Index Vectors*

### Description

Class `index` is a virtual class designating index vectors, or “subscripts”, for (possibly named) vectors and arrays. It is typically used in signatures of methods for the subscript and subassignment operators, namely `[]` and `[-<-`. It is implemented as a *union* of the atomic vector classes `numeric`, `logical`, and `character`.

### See Also

`[]`, `[-methods`, and `[-<-methods`.

### Examples

```
showClass("index")
```

indMatrix-class

*Index Matrices*

### Description

The `indMatrix` class is the class of row and column *index* matrices, stored as 1-based integer index vectors. A row (column) index matrix is a matrix whose rows (columns) are standard unit vectors. Such matrices are useful when mapping observations to discrete sets of covariate values.

Multiplying a matrix on the left by a row index matrix is equivalent to indexing its rows, i.e., sampling the rows “with replacement”. Analogously, multiplying a matrix on the right by a column index matrix is equivalent to indexing its columns. Indeed, such products are implemented in **Matrix** as indexing operations; see ‘Details’ below.

A matrix whose rows *and* columns are standard unit vectors is called a *permutation* matrix. This special case is designated by the `pMatrix` class, a direct subclass of `indMatrix`.

### Details

The transpose of an index matrix is an index matrix with identical `perm` but opposite `margin`. Hence the transpose of a row index matrix is a column index matrix, and vice versa.

The cross product of a row index matrix `R` and itself is a diagonal matrix whose diagonal entries are the the number of entries in each column of `R`.

Given a row index matrix `R` with `perm` slot `p`, a column index matrix `C` with `perm` slot `q`, and a matrix `M` with conformable dimensions, we have

```

RM    = R %**% M           = M[p, ]
MC    = M %**% C           = M[, q]
C'M   = crossprod(C, M)    = M[q, ]
MR'   = tcrossprod(M, R)   = M[, p]
R'R   = crossprod(R)       = Diagonal(x=tabulate(p, ncol(R)))
CC'   = tcrossprod(C)      = Diagonal(x=tabulate(q, nrow(C)))

```

Operations on index matrices that result in index matrices will accordingly return an `indMatrix`. These include products of two column index matrices and (equivalently) column-indexing of a column index matrix (when dimensions are not dropped). Most other operations on `indMatrix` treat them as sparse nonzero pattern matrices (i.e., inheriting from virtual class `nsparseMatrix`). Hence vector-valued subsets of `indMatrix`, such as those given by `diag`, are always of type `"logical"`.

### Objects from the Class

Objects can be created explicitly with calls of the form `new("indMatrix", ...)`, but they are more commonly created by coercing 1-based integer index vectors, with calls of the form `as(., "indMatrix")`; see ‘Methods’ below.

### Slots

`margin` an integer, either 1 or 2, specifying whether the matrix is a row (1) or column (2) index.  
`perm` a 1-based integer index vector, i.e., a vector of length `Dim[margin]` with elements taken from `1:Dim[1+margin%%2]`.  
`Dim, Dimnames` inherited from virtual superclass `Matrix`.

### Extends

Classes `"sparseMatrix"` and `"generalMatrix"`, directly.

### Methods

```

%** signature(x = "indMatrix", y = "Matrix") and others listed by
showMethods("%**%", classes = "indMatrix"): matrix products implemented
where appropriate as indexing operations.

coerce signature(from = "numeric", to = "indMatrix"): supporting typical
indMatrix construction from a vector of positive integers. Row indexing is assumed.

coerce signature(from = "list", to = "indMatrix"): supporting indMatrix
construction for row and column indexing, including index vectors of length 0 and index
vectors whose maximum is less than the number of rows or columns being indexed.

coerce signature(from = "indMatrix", to = "matrix"): coercion to a traditional
matrix of logical type, with FALSE and TRUE in place of 0 and 1.

t signature(x = "indMatrix"): the transpose, which is an indMatrix with identical
perm but opposite margin.

rowSums, rowMeans, colSums, colMeans signature(x = "indMatrix"): row and
column sums and means.

rbind2, cbind2 signature(x = "indMatrix", y = "indMatrix"): row-wise catenation
of two row index matrices with equal numbers of columns and column-wise catenation
of two column index matrices with equal numbers of rows.

```

**kronecker** signature (X = "indMatrix", Y = "indMatrix"): Kronecker product of two row index matrices or two column index matrices, giving the row or column index matrix corresponding to their “interaction”.

### Author(s)

Fabian Scheipl at ‘uni-muenchen.de’, building on the existing class `pMatrix` after a nice hike’s conversation with Martin Maechler. Methods for `crossprod(x, y)` and `kronecker(x, y)` with both arguments inheriting from `indMatrix` were made considerably faster thanks to a suggestion by Boris Vaillant. Diverse tweaks by Martin Maechler and Mikael Jagan, notably the latter’s implementation of `margin`, prior to which the `indMatrix` class was designated only for row index matrices.

### See Also

Subclass `pMatrix` of permutation matrices, a special case of index matrices; virtual class `nMatrix` of nonzero pattern matrices, and its subclasses.

### Examples

```
p1 <- as(c(2,3,1), "pMatrix")
(sm1 <- as(rep(c(2,3,1), e=3), "indMatrix"))
stopifnot(all(sm1 == p1[rep(1:3, each=3),]))

## row-indexing of a <pMatrix> turns it into an <indMatrix>:
class(p1[rep(1:3, each=3),])

set.seed(12) # so we know '10' is in sample
## random index matrix for 30 observations and 10 unique values:
(s10 <- as(sample(10, 30, replace=TRUE), "indMatrix"))

## Sample rows of a numeric matrix :
(mm <- matrix(1:10, nrow=10, ncol=3))
s10 %*% mm

set.seed(27)
IM1 <- as(sample(1:20, 100, replace=TRUE), "indMatrix")
IM2 <- as(sample(1:18, 100, replace=TRUE), "indMatrix")
(c12 <- crossprod(IM1, IM2))
## same as cross-tabulation of the two index vectors:
stopifnot(all(c12 - unclass(table(IM1@perm, IM2@perm)) == 0))

# 3 observations, 4 implied values, first does not occur in sample:
as(2:4, "indMatrix")
# 3 observations, 5 values, first and last do not occur in sample:
as(list(2:4, 5), "indMatrix")

as(sm1, "nMatrix")
s10[1:7, 1:4] # gives an "ngTMatrix" (most economic!)
s10[1:4, ] # preserves "indMatrix"-class

I1 <- as(c(5:1, 6:4, 7:3), "indMatrix")
I2 <- as(7:1, "pMatrix")
(I12 <- rbind(I1, I2))
stopifnot(is(I12, "indMatrix"),
          identical(I12, rbind(I1, I2)),
```

```
colSums(I12) == c(2L, 2:4, 4:2))
```

invertPerm

*Utilities for Permutation Vectors*

## Description

`invertPerm` and `signPerm` compute the inverse and sign of a length-`n` permutation vector. `isPerm` tests if a length-`n` integer vector is a valid permutation vector. `asPerm` coerces a length-`m` transposition vector to a length-`n` permutation vector, where `m` <= `n`.

## Usage

```
invertPerm(p, off = 1L, ioff = 1L)
signPerm(p, off = 1L)
isPerm(p, off = 1L)
asPerm(pivot, off = 1L, ioff = 1L, n = length(pivot))

invPerm(p, zero.p = FALSE, zero.res = FALSE)
```

## Arguments

|                       |   |
|-----------------------|---|
| <code>p</code>        | an integer vector of length <code>n</code> .  |
| <code>pivot</code>    | an integer vector of length <code>m</code> .  |
| <code>off</code>      | an integer offset, indicating that <code>p</code> is a permutation of <code>off+0:(n-1)</code> or that <code>pivot</code> contains <code>m</code> values sampled with replacement from <code>off+0:(n-1)</code> . |
| <code>ioff</code>     | an integer offset, indicating that the result should be a permutation of <code>ioff+0:(n-1)</code> .  |
| <code>n</code>        | a integer greater than or equal to <code>m</code> , indicating the length of the result. Transpositions are applied to a permutation vector initialized as <code>seq_len(n)</code> .                              |
| <code>zero.p</code>   | a logical. Equivalent to <code>off=0</code> if TRUE and <code>off=1</code> if FALSE.  |
| <code>zero.res</code> | a logical. Equivalent to <code>ioff=0</code> if TRUE and <code>ioff=1</code> if FALSE.  |

## Details

`invertPerm(p, off, ioff=1)` is equivalent to `order(p)` or `sort.list(p)` for all values of `off`. For the default value `off=1`, it returns the value of `p` after `p[p] <- seq_along(p)`. `invPerm` is a simple wrapper around `invertPerm`, retained for backwards compatibility.

## Value

By default, i.e., with `off=1` and `ioff=1`:

`invertPerm(p)` returns an integer vector of length `length(p)` such that `p[invertPerm(p)]` and `invertPerm(p)[p]` are both `seq_along(p)`, i.e., the identity permutation.

`signPerm(p)` returns 1 if `p` is an even permutation and -1 otherwise (i.e., if `p` is odd).

`isPerm(p)` returns TRUE if `p` is a permutation of `seq_along(p)` and FALSE otherwise.

`asPerm(pivot)` returns the result of transposing elements `i` and `pivot[i]` of a permutation vector initialized as `seq_len(n)`, for `i` in `seq_along(pivot)`.

**See Also**

Class `pMatrix` of permutation matrices.

**Examples**

```
p <- sample(10L) # a random permutation vector
ip <- invertPerm(p)
s <- signPerm(p)

## 'p' and 'ip' are indeed inverses:
stopifnot(exprs = {
  isPerm(p)
  isPerm(ip)
  identical(s, 1L) || identical(s, -1L)
  identical(s, signPerm(ip))
  identical(p[ip], 1:10)
  identical(ip[p], 1:10)
  identical(invertPerm(ip), p)
})

## Product of transpositions (1 2)(2 1)(4 3)(6 8)(10 1) = (3 4)(6 8)(1 10)
pivot <- c(2L, 1L, 3L, 3L, 5L, 8L, 7L, 8L, 9L, 1L)
q <- asPerm(pivot)
stopifnot(exprs = {
  identical(q, c(10L, 2L, 4L, 3L, 5L, 8L, 7L, 6L, 9L, 1L))
  identical(q[q], seq_len(10L)) # because the permutation is odd:
  signPerm(q) == -1L
})

invPerm # a less general version of 'invertPerm'
```

---

is.na-methods

*is.na()*, *is.finite()* *Methods for 'Matrix' Objects*

---

**Description**

Methods for generic functions `anyNA()`, `is.na()`, `is.nan()`, `is.infinite()`, and `is.finite()`, for objects inheriting from virtual class `Matrix` or `sparseVector`.

**Usage**

```
## S4 method for signature 'denseMatrix'
is.na(x)
## S4 method for signature 'sparseMatrix'
is.na(x)
## S4 method for signature 'diagonalMatrix'
is.na(x)
## S4 method for signature 'indMatrix'
is.na(x)
## S4 method for signature 'sparseVector'
is.na(x)
## ...
## and likewise for anyNA, is.nan, is.infinite, is.finite
```

**Arguments**

`x` an R object, here a sparse or dense matrix or vector.

**Value**

For `is.*()`, an `nMatrix` or `nsparseVector` matching the dimensions of `x` and specifying the positions in `x` of (some subset of) `NA`, `NaN`, `Inf`, and `-Inf`. For `anyNA()`, `TRUE` if `x` contains `NA` or `NaN` and `FALSE` otherwise.

**See Also**

[NA](#), [NaN](#), [Inf](#)

**Examples**

```
(M <- Matrix(1:6, nrow = 4, ncol = 3,
            dimnames = list(letters[1:4], LETTERS[1:3])))
stopifnot(!anyNA(M), !any(is.na(M)))

M[2:3, 2] <- NA
(inM <- is.na(M))
stopifnot(anyNA(M), sum(inM) == 2)

(A <- spMatrix(nrow = 10, ncol = 20,
              i = c(1, 3:8), j = c(2, 9, 6:10), x = 7 * (1:7)))
stopifnot(!anyNA(A), !any(is.na(A)))

A[2, 3] <- A[1, 2] <- A[5, 5:9] <- NA
(inA <- is.na(A))
stopifnot(anyNA(A), sum(inA) == 1 + 1 + 5)
```

---

is.null.DN

*Are the Dimnames dn NULL-like ?*

---

**Description**

Are the `dimnames` `dn` `NULL`-like?

`is.null.DN(dn)` is less strict than `is.null(dn)`, because it is also true (`TRUE`) when the `dimnames` `dn` are “like” `NULL`, or `list(NULL, NULL)`, as they can easily be for the traditional R matrices (`matrix`) which have no formal `class` definition, and hence much freedom in how their `dimnames` look like.

**Usage**

```
is.null.DN(dn)
```

**Arguments**

`dn` `dimnames()` of a `matrix`-like R object.

**Value**

logical `TRUE` or `FALSE`.

**Note**

This function is really to be used on “traditional” matrices rather than those inheriting from `Matrix`, as the latter will always have `dimnames` `list(NULL, NULL)` exactly, in such a case.

**Author(s)**

Martin Maechler

**See Also**

`is.null`, `dimnames`, `matrix`.

**Examples**

```
m1 <- m2 <- m3 <- m4 <- m <-
  matrix(round(100 * rnorm(6)), 2, 3)
dimnames(m1) <- list(NULL, NULL)
dimnames(m2) <- list(NULL, character())
dimnames(m3) <- rev(dimnames(m2))
dimnames(m4) <- rep(list(character()), 2)

m4 # prints absolutely identically to m

c.o <- capture.output
cm <- c.o(m)
stopifnot(exprs = {
  m == m1; m == m2; m == m3; m == m4
  identical(cm, c.o(m1)); identical(cm, c.o(m2))
  identical(cm, c.o(m3)); identical(cm, c.o(m4))
})

hasNoDimnames <- function(.) is.null.DN(dimnames(.))
stopifnot(exprs = {
  hasNoDimnames(m)
  hasNoDimnames(m1); hasNoDimnames(m2)
  hasNoDimnames(m3); hasNoDimnames(m4)
  hasNoDimnames(Matrix(m) -> M)
  hasNoDimnames(as(M, "sparseMatrix"))
})
```

---

isSymmetric-methods

*Methods for Function 'isSymmetric' in Package 'Matrix'*

---

**Description**

`isSymmetric` tests whether its argument is a symmetric square matrix, by default tolerating some numerical fuzz and requiring symmetric [dD]imnames in addition to symmetry in the mathematical sense. `isSymmetric` is a generic function in **base**, which has a [method](#) for traditional matrices of implicit class `"matrix"`. Methods are defined here for various proper and virtual classes in **Matrix**, so that `isSymmetric` works for all objects inheriting from virtual class `"Matrix"`.

## Usage

```
## S4 method for signature 'denseMatrix'
isSymmetric(object, checkDN = TRUE, ...)
## S4 method for signature 'CsparseMatrix'
isSymmetric(object, checkDN = TRUE, ...)
## S4 method for signature 'RsparseMatrix'
isSymmetric(object, checkDN = TRUE, ...)
## S4 method for signature 'TsparseMatrix'
isSymmetric(object, checkDN = TRUE, ...)
## S4 method for signature 'diagonalMatrix'
isSymmetric(object, checkDN = TRUE, ...)
## S4 method for signature 'indMatrix'
isSymmetric(object, checkDN = TRUE, ...)
## S4 method for signature 'dgeMatrix'
isSymmetric(object, checkDN = TRUE, tol = 100 * .Machine$double.eps, toll = 8 *
## S4 method for signature 'dgCMatrix'
isSymmetric(object, checkDN = TRUE, tol = 100 * .Machine$double.eps, ...)
```

## Arguments

|           |  |
|-----------|--|
| object    | a "Matrix".  |
| checkDN   | a <a href="#">logical</a> indicating whether symmetry of the Dimnames <a href="#">slot</a> of object should be checked.                            |
| tol, toll | numerical tolerances allowing <i>approximate</i> symmetry of numeric (rather than logical) matrices. See also <a href="#">isSymmetric.matrix</a> . |
| ...       | further arguments passed to methods (typically methods for <a href="#">all.equal</a> ).  |

## Details

The Dimnames [slot](#) of object, say dn, is considered to be symmetric if and only if

- `dn[[1]]` and `dn[[2]]` are identical *or* one is NULL; *and*
- `ndn <- names(dn)` is NULL *or* `ndn[1]` and `ndn[2]` are identical *or* one is the empty string `" "`.

Hence `list(a=nms, a=nms)` is considered to be *symmetric*, and so too are `list(a=nms, NULL)` and `list(NULL, a=nms)`.

Note that this definition is *looser* than that employed by [isSymmetric.matrix](#), which requires `dn[1]` and `dn[2]` to be identical, where dn is the dimnames [attribute](#) of a traditional matrix.

## Value

A [logical](#), either TRUE or FALSE (never [NA](#)).

## See Also

[forceSymmetric](#); [symmpart](#) and [skewpart](#); virtual class `"symmetricMatrix"` and its subclasses.

**Examples**

```

isSymmetric(Diagonal(4)) # TRUE of course
M <- Matrix(c(1,2,2,1), 2,2)
isSymmetric(M) # TRUE (*and* of formal class "dsyMatrix")
isSymmetric(as(M, "generalMatrix")) # still symmetric, even if not "formally"
isSymmetric(triu(M)) # FALSE

## Look at implementations:
showMethods("isSymmetric", includeDefs = TRUE) # includes S3 generic from base

```

---

isTriangular-methods

*Test whether a Matrix is Triangular or Diagonal*

---

**Description**

`isTriangular` and `isDiagonal` test whether their argument is a triangular or diagonal matrix, respectively. Unlike the analogous `isSymmetric`, these two functions are generically from **Matrix** rather than `base`. Hence **Matrix** defines methods for traditional matrices of implicit class `"matrix"` in addition to matrices inheriting from virtual class `"Matrix"`.

By our definition, triangular and diagonal matrices are *square*, i.e., they have the same number of rows and columns.

**Usage**

```

isTriangular(object, upper = NA, ...)

isDiagonal(object)

```

**Arguments**

|                     |   |
|---------------------|---|
| <code>object</code> | an R object, typically a matrix.  |
| <code>upper</code>  | a <b>logical</b> , either <code>TRUE</code> or <code>FALSE</code> , in which case <code>TRUE</code> is returned only for upper or lower triangular object; or otherwise <code>NA</code> (the default), in which case <code>TRUE</code> is returned for any triangular object. |
| <code>...</code>    | further arguments passed to methods (currently unused by <b>Matrix</b> ).   |

**Value**

A **logical**, either `TRUE` or `FALSE` (never `NA`).

If `object` is triangular and `upper` is `NA`, then `isTriangular` returns `TRUE` with an **attribute** `kind`, either `"U"` or `"L"`, indicating that `object` is **upper** or **lower** triangular, respectively. Users should not rely on how `kind` is determined for diagonal matrices, which are both upper and lower triangular.

**See Also**

`isSymmetric`; virtual classes `"triangularMatrix"` and `"diagonalMatrix"` and their subclasses.

## Examples

```
isTriangular(Diagonal(4))
## is TRUE: a diagonal matrix is also (both upper and lower) triangular
(M <- Matrix(c(1,2,0,1), 2,2))
isTriangular(M) # TRUE (*and* of formal class "dtrMatrix")
isTriangular(as(M, "generalMatrix")) # still triangular, even if not "formally"
isTriangular(crossprod(M)) # FALSE

isDiagonal(matrix(c(2,0,0,1), 2,2)) # TRUE

## Look at implementations:
showMethods("isTriangular", includeDefs = TRUE)
showMethods("isDiagonal", includeDefs = TRUE)
```

---

KhatriRao

*Khatri-Rao Matrix Product*

---

## Description

Computes Khatri-Rao products for any kind of matrices.

The Khatri-Rao product is a column-wise Kronecker product. Originally introduced by Khatri and Rao (1968), it has many different applications, see Liu and Trenkler (2008) for a survey. Notably, it is used in higher-dimensional tensor decompositions, see Bader and Kolda (2008).

## Usage

```
KhatriRao(X, Y = X, FUN = "*", sparseY = TRUE, make.dimnames = FALSE)
```

## Arguments

|               |   |
|---------------|---|
| X, Y          | matrices of with the same number of columns.  |
| FUN           | the (name of the) <a href="#">function</a> to be used for the column-wise Kronecker products, see <a href="#">kronecker</a> , defaulting to the usual multiplication. |
| sparseY       | logical specifying if Y should be coerced and treated as <a href="#">sparseMatrix</a> . Set this to FALSE, e.g., to distinguish structural zeros from zero entries.   |
| make.dimnames | logical indicating if the result should inherit <a href="#">dimnames</a> from X and Y in a simple way.  |

## Value

a "[CsparseMatrix](#)", say R, the Khatri-Rao product of X ( $n \times k$ ) and Y ( $m \times k$ ), is of dimension  $(n \cdot m) \times k$ , where the j-th column,  $R[, j]$  is the kronecker product [kronecker](#)( $X[, j]$ ,  $Y[, j]$ ).

## Note

The current implementation is efficient for large sparse matrices.

## Author(s)

Original by Michael Cysouw, Univ. Marburg; minor tweaks, bug fixes etc, by Martin Maechler.

})

```

KNex

*Koenker-Ng Example Sparse Model Matrix and Response Vector*

## Description

A model matrix `mm` and corresponding response vector `y` used in an example by Koenker and Ng. The matrix `mm` is a sparse matrix with 1850 rows and 712 columns but only 8758 non-zero entries. It is a "dgCMatrix" object. The vector `y` is just `numeric` of length 1850.

## Usage

```
data(KNex)
```

## References

Roger Koenker and Pin Ng (2003). SparseM: A sparse matrix package for R; *J. of Statistical Software*, **8** (6), [doi:10.18637/jss.v008.i06](https://doi.org/10.18637/jss.v008.i06)

## Examples

```

data(KNex, package = "Matrix")
class(KNex$mm)
dim(KNex$mm)
image(KNex$mm)
str(KNex)

system.time( # a fraction of a second
  sparse.sol <- with(KNex, solve(crossprod(mm), crossprod(mm, y))))

head(round(sparse.sol, 3))

## Compare with QR-based solution ("more accurate, but slightly slower"):
system.time(
  sp.sol2 <- with(KNex, qr.coef(qr(mm), y) ))

all.equal(sparse.sol, sp.sol2, tolerance = 1e-13) # TRUE

```

---

kronecker-methods    *Methods for Function 'kronecker()' in Package 'Matrix'*

---

## Description

Computes Kronecker products for objects inheriting from "[Matrix](#)".

In order to preserve sparseness, we treat  $0 * NA$  as 0, not as [NA](#) as usually in R (and as used for the base function [kronecker](#)).

## Methods

```
kronecker signature(X = "Matrix", Y = "ANY") .....
kronecker signature(X = "ANY", Y = "Matrix") .....
kronecker signature(X = "diagonalMatrix", Y = "ANY") .....
kronecker signature(X = "sparseMatrix", Y = "ANY") .....
kronecker signature(X = "TsparseMatrix", Y = "TsparseMatrix") .....
kronecker signature(X = "dgTMatrix", Y = "dgTMatrix") .....
kronecker signature(X = "dtTMatrix", Y = "dtTMatrix") .....
kronecker signature(X = "indMatrix", Y = "indMatrix") .....
```

## Examples

```
(t1 <- spMatrix(5,4, x= c(3,2,-7,11), i= 1:4, j=4:1)) # 5 x 4
(t2 <- kronecker(Diagonal(3, 2:4), t1)) # 15 x 12

## should also work with special-cased logical matrices
l3 <- upper.tri(matrix(,3,3))
M <- Matrix(l3)
(N <- as(M, "nsparseMatrix")) # "ntCMatrix" (upper triangular)
N2 <- as(N, "generalMatrix") # (lost "triangularity")
MM <- kronecker(M,M)
NN <- kronecker(N,N) # "dtTMatrix" i.e. did keep
NN2 <- kronecker(N2,N2)
stopifnot(identical(NN,MM),
           is(NN2, "sparseMatrix"), all(NN2 == NN),
           is(NN, "triangularMatrix"))
```

---

ldenseMatrix-class    *Virtual Class "ldenseMatrix" of Dense Logical Matrices*

---

## Description

`ldenseMatrix` is the virtual class of all dense logical (S4) matrices. It extends both [denseMatrix](#) and [lMatrix](#) directly.

## Slots

**x:** logical vector containing the entries of the matrix.

**Dim, Dimnames:** see [Matrix](#).

**Extends**

Class "lMatrix", directly. Class "denseMatrix", directly. Class "Matrix", by class "lMatrix". Class "Matrix", by class "denseMatrix".

**Methods**

**as.vector** signature(x = "ldenseMatrix", mode = "missing"): ...  
**which** signature(x = "ndenseMatrix"), semantically equivalent to **base** function `which(x, arr.ind)`; for details, see the [lMatrix](#) class documentation.

**See Also**

Class [lgeMatrix](#) and the other subclasses.

**Examples**

```
showClass("ldenseMatrix")

as(diag(3) > 0, "ldenseMatrix")
```

---

ldiMatrix-class

---

Class "ldiMatrix" of Diagonal Logical Matrices

---

**Description**

The class "ldiMatrix" of logical diagonal matrices.

**Objects from the Class**

Objects can be created by calls of the form `new("ldiMatrix", ...)` but typically rather via [Diagonal](#).

**Slots**

**x**: "logical" vector.  
**diag**: "character" string, either "U" or "N", see [ddiMatrix](#).  
**Dim,Dimnames**: matrix dimension and **dimnames**, see the [Matrix](#) class description.

**Extends**

Class "[diagonalMatrix](#)" and class "[lMatrix](#)", directly.  
Class "[sparseMatrix](#)", by class "[diagonalMatrix](#)".

**See Also**

Classes [ddiMatrix](#) and [diagonalMatrix](#); function [Diagonal](#).

**Examples**

```
(lM <- Diagonal(x = c(TRUE,FALSE,FALSE)))
str(lM) #> gory details (slots)

crossprod(lM) # numeric
(nM <- as(lM, "nMatrix"))
crossprod(nM) # pattern sparse
```

---

lgeMatrix-class      *Class "lgeMatrix" of General Dense Logical Matrices*

---

**Description**

This is the class of general dense [logical](#) matrices.

**Slots**

**x:** Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

**Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#) class.

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

**Extends**

Class "ldenseMatrix", directly. Class "lMatrix", by class "ldenseMatrix". Class "denseMatrix", by class "ldenseMatrix". Class "Matrix", by class "ldenseMatrix". Class "Matrix", by class "ldenseMatrix".

**Methods**

Currently, mainly [t\(\)](#) and coercion methods (for [as\(.\)](#)); use, e.g., [showMethods](#)(class="lgeMatrix") for details.

**See Also**

Non-general logical dense matrix classes such as [ltrMatrix](#), or [lsyMatrix](#); *sparse* logical classes such as [lgCMatrix](#).

**Examples**

```
showClass("lgeMatrix")
str(new("lgeMatrix"))
set.seed(1)
(lM <- Matrix(matrix(rnorm(28), 4,7) > 0)) # a simple random lgeMatrix
set.seed(11)
(lC <- Matrix(matrix(rnorm(28), 4,7) > 0)) # a simple random lgCMatrix
as(lM, "CsparseMatrix")
```

---

lsparseMatrix-class

*Sparse logical matrices*

---

## Description

The `lsparseMatrix` class is a virtual class of logical sparse matrices, i.e., sparse matrices with entries `TRUE`, `FALSE`, or `NA`.

These can be stored in the “triplet” form (class `TsparseMatrix`, subclasses `lgTMatrix`, `lsTMatrix`, and `ltTMatrix`) or in compressed column-oriented form (class `CsparseMatrix`, subclasses `lgCMatrix`, `lsCMatrix`, and `ltCMatrix`) or—rarely—in compressed row-oriented form (class `RsparseMatrix`, subclasses `lgRMatrix`, `lsRMatrix`, and `ltRMatrix`). The second letter in the name of these non-virtual classes indicates general, symmetric, or triangular.

## Details

Note that triplet stored (`TsparseMatrix`) matrices such as `lgTMatrix` may contain duplicated pairs of indices  $(i, j)$  as for the corresponding numeric class `dgTMatrix` where for such pairs, the corresponding `x` slot entries are added. For logical matrices, the `x` entries corresponding to duplicated index pairs  $(i, j)$  are “added” as well if the addition is defined as logical *or*, i.e., “`TRUE + TRUE`  $\rightarrow$  `TRUE`” and “`TRUE + FALSE`  $\rightarrow$  `TRUE`”. Note the use of `asUniqueT()` for getting an internally unique representation without duplicated  $(i, j)$  entries.

## Objects from the Class

Objects can be created by calls of the form `new("lgCMatrix", ...)` and so on. More frequently objects are created by coercion of a numeric sparse matrix to the logical form, e.g. in an expression `x != 0`.

The logical form is also used in the symbolic analysis phase of an algorithm involving sparse matrices. Such algorithms often involve two phases: a symbolic phase wherein the positions of the non-zeros in the result are determined and a numeric phase wherein the actual results are calculated. During the symbolic phase only the positions of the non-zero elements in any operands are of interest, hence any numeric sparse matrices can be treated as logical sparse matrices.

## Slots

- x:** Object of class `"logical"`, i.e., either `TRUE`, `NA`, or `FALSE`.
- uplo:** Object of class `"character"`. Must be either `"U"`, for upper triangular, and `"L"`, for lower triangular. Present in the triangular and symmetric classes but not in the general class.
- diag:** Object of class `"character"`. Must be either `"U"`, for unit triangular (diagonal is all ones), or `"N"` for non-unit. The implicit diagonal elements are not explicitly stored when `diag` is `"U"`. Present in the triangular classes only.
- p:** Object of class `"integer"` of pointers, one for each column (row), to the initial (zero-based) index of elements in the column. Present in compressed column-oriented and compressed row-oriented forms only.
- i:** Object of class `"integer"` of length `nnzero` (number of non-zero elements). These are the row numbers for each `TRUE` element in the matrix. All other elements are `FALSE`. Present in triplet and compressed column-oriented forms only.

**j**: Object of class "integer" of length nnzero (number of non-zero elements). These are the column numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed row-oriented forms only.

**Dim**: Object of class "integer" - the dimensions of the matrix.

## Methods

**coerce** signature (from = "dgCMatrix", to = "lgCMatrix")

**t** signature (x = "lgCMatrix"): returns the transpose of x

**which** signature (x = "lsparseMatrix"), semantically equivalent to **base** function `which(x, arr.ind)`; for details, see the [lMatrix](#) class documentation.

## See Also

the class [dgCMatrix](#) and [dgTMatrix](#)

## Examples

```
(m <- Matrix(c(0,0,2:0), 3,5, dimnames=list(LETTERS[1:3],NULL)))
(lm <- (m > 1)) # lgC
!lm           # no longer sparse
stopifnot(is(lm,"lsparseMatrix"),
           identical(!lm, m <= 1))

data(KNex, package = "Matrix")
str(mmG.1 <- (KNex $ mm) > 0.1) # "lgC..."
table(mmG.1@x) # however with many ``non-structural zeros''
## from logical to nz_pattern -- okay when there are no NA's :
nmG.1 <- as(mmG.1, "nMatrix") # <<< has "TRUE" also where mmG.1 had FALSE
## from logical to "double"
dmG.1 <- as(mmG.1, "dMatrix") # has '0' and back:
lmG.1 <- as(dmG.1, "lMatrix")
stopifnot(identical(nmG.1, as((KNex $ mm) != 0, "nMatrix")),
           validObject(lmG.1),
           identical(lmG.1, mmG.1))

class(xnx <- crossprod(nmG.1)) # "nsC.."
class(xlx <- crossprod(mmG.1)) # "dsC.." : numeric
is0 <- (xlx == 0)
mean(as.vector(is0)) # 99.3% zeros: quite sparse, but
table(xlx@x == 0) # more than half of the entries are (non-structural!) 0
stopifnot(isSymmetric(xlx), isSymmetric(xnx),
           ## compare xnx and xlx : have the *same* non-structural 0s :
           sapply(slotNames(xnx),
                   function(n) identical(slot(xnx, n), slot(xlx, n)))))
```

## Description

The "lsyMatrix" class is the class of symmetric, dense logical matrices in non-packed storage and "lspMatrix" is the class of these in packed storage. In the packed form, only the upper triangle or the lower triangle is stored.

## Objects from the Class

Objects can be created by calls of the form `new("lsyMatrix", ...)`.

## Slots

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**x:** Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

**Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#) class.

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

## Extends

Both extend classes "[ldenseMatrix](#)" and "[symmetricMatrix](#)", directly; further, class "[Matrix](#)" and others, *indirectly*. Use `showClass("lsyMatrix")`, e.g., for details.

## Methods

Currently, mainly `t()` and coercion methods (for `as(.)`; use, e.g., `showMethods(class="lsyMatrix")` for details.

## See Also

[lgeMatrix](#), [Matrix](#), [t](#)

## Examples

```
(M2 <- Matrix(c(TRUE, NA, FALSE, FALSE), 2, 2)) # logical dense (ltr)
str(M2)
# can
(sM <- M2 | t(M2)) # "lge"
as(sM, "symmetricMatrix")
str(sM <- as(sM, "packedMatrix")) # packed symmetric
```

---

|                 |  |
|-----------------|--|
| ltrMatrix-class | <i>Triangular Dense Logical Matrices</i> |
|-----------------|--|

---

## Description

The "[ltrMatrix](#)" class is the class of triangular, dense, logical matrices in nonpacked storage. The "[ltpMatrix](#)" class is the same except in packed storage.

**Slots**

- x:** Object of class "logical". The logical values that constitute the matrix, stored in column-major order.
- uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.
- diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see [triangularMatrix](#).
- Dim, Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#) class.
- factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

**Extends**

Both extend classes "[ldenseMatrix](#)" and "[triangularMatrix](#)", directly; further, class "[Matrix](#)", "[lMatrix](#)" and others, *indirectly*. Use [showClass\("ltrMatrix"\)](#), e.g., for details.

**Methods**

Currently, mainly [t\(\)](#) and coercion methods (for [as\(.\)](#); use, e.g., [showMethods\(class="ltrMatrix"\)](#) for details.

**See Also**

Classes [lgeMatrix](#), [Matrix](#); function [t](#)

**Examples**

```
showClass("ltrMatrix")

str(new("ltpMatrix"))
(lutr <- as(upper.tri(matrix(, 4, 4)), "ldenseMatrix"))
str(lutp <- pack(lutr)) # packed matrix: only 10 = 4*(4+1)/2 entries
!lutp # the logical negation (is *not* logical triangular !)
## but this one is:
stopifnot(all.equal(lutp, pack(!!lutp)))
```

**Description**

Computes the pivoted LU factorization of an  $m \times n$  real matrix  $A$ , which has the general form

$$P_1 A P_2 = LU$$

or (equivalently)

$$A = P_1' L U P_2'$$

where  $P_1$  is an  $m \times m$  permutation matrix,  $P_2$  is an  $n \times n$  permutation matrix,  $L$  is an  $m \times \min(m, n)$  unit lower trapezoidal matrix, and  $U$  is a  $\min(m, n) \times n$  upper trapezoidal matrix.

Methods for `denseMatrix` are built on LAPACK routine `dgetrf`, which does not permute columns, so that  $P_2$  is an identity matrix.

Methods for `sparseMatrix` are built on CXSparse routine `cs_lu`, which requires  $m = n$ , so that  $L$  and  $U$  are triangular matrices.

## Usage

```
lu(x, ...)
## S4 method for signature 'dgeMatrix'
lu(x, warnSing = TRUE, ...)
## S4 method for signature 'dgCMatrix'
lu(x, errSing = TRUE, order = NA_integer_,
   tol = 1, ...)
## S4 method for signature 'dsyMatrix'
lu(x, cache = TRUE, ...)
## S4 method for signature 'dsCMatrix'
lu(x, cache = TRUE, ...)
## S4 method for signature 'matrix'
lu(x, ...)
```

## Arguments

|                       |  |
|-----------------------|--|
| <code>x</code>        | a <a href="#">finite</a> matrix or <a href="#">Matrix</a> to be factorized, which must be square if sparse.  |
| <code>warnSing</code> | a logical indicating if a <a href="#">warning</a> should be signaled for singular <code>x</code> . Used only by methods for dense matrices.  |
| <code>errSing</code>  | a logical indicating if an <a href="#">error</a> should be signaled for singular <code>x</code> . Used only by methods for sparse matrices.  |
| <code>order</code>    | an integer in <code>0:3</code> passed to CXSparse routine <code>cs_sqr</code> , indicating a strategy for choosing the column permutation $P_2$ . 0 means no column permutation. 1, 2, and 3 indicate a fill-reducing ordering of $A + A'$ , $\tilde{A}'\tilde{A}$ , and $A'A$ , where $\tilde{A}$ is $A$ with “dense” rows removed. NA (the default) is equivalent to 2 if <code>tol == 1</code> and 1 otherwise. Do not set to 0 unless you know that the column order of $A$ is already sensible. |
| <code>tol</code>      | a number. The original pivot element is used if its absolute value exceeds <code>tol * a</code> , where <code>a</code> is the maximum in absolute value of the other possible pivot elements. Set <code>tol &lt; 1</code> only if you know what you are doing.   |
| <code>cache</code>    | a logical indicating if the result should be cached in <code>x@factors[["LU"]]</code> . Note that caching is experimental and that only methods for classes extending <a href="#">generalMatrix</a> or <a href="#">symmetricMatrix</a> will have this argument.  |
| <code>...</code>      | further arguments passed to or from methods.   |

## Details

What happens when `x` is determined to be near-singular differs by method. The method for class `dgeMatrix` completes the factorization, warning if `warnSing = TRUE` and in any case returning a valid `denseLU` object. Users of this method can detect singular `x` with a suitable warning handler; see [tryCatch](#). In contrast, the method for class `dgCMatrix` abandons further computation, throwing an error if `errSing = TRUE` and otherwise returning NA. Users of this method can detect singular `x` with an error handler or by setting `errSing = FALSE` and testing for a formal result with `is(., "sparseLU")`.

## Value

An object representing the factorization, inheriting from virtual class `LU`. The specific class is `denseLU` unless `x` inherits from virtual class `sparseMatrix`, in which case it is `sparseLU`.

## Examples

```
showMethods("lu", inherited = FALSE)
set.seed(0)

## ---- Dense -----

(A1 <- Matrix(rnorm(9L), 3L, 3L))
(lu.A1 <- lu(A1))

(A2 <- round(10 * A1[, -3L]))
(lu.A2 <- lu(A2))

## A ~ P1' L U in floating point
str(e.lu.A2 <- expand2(lu.A2), max.level = 2L)
stopifnot(all.equal(A2, Reduce(`%*%`, e.lu.A2)))

## ---- Sparse -----

A3 <- as(readMM(system.file("external/pores_1.mtx", package = "Matrix")),
         "CsparseMatrix")
(lu.A3 <- lu(A3))

## A ~ P1' L U P2' in floating point
str(e.lu.A3 <- expand2(lu.A3), max.level = 2L)
stopifnot(all.equal(A3, Reduce(`%*%`, e.lu.A3)))
```

mat2triplet

*Map Matrix to its Triplet Representation***Description**

From an R object coercible to `"TsparseMatrix"`, typically a (sparse) matrix, produce its triplet representation which may collapse to a “Duplet” in the case of binary aka pattern, such as `"nMatrix"` objects.

**Usage**

```
mat2triplet(x, uniqT = FALSE)
```

**Arguments**

`x` any R object for which `as(x, "TsparseMatrix")` works; typically a `matrix` of one of the **Matrix** package matrices.

`uniqT` `logical` indicating if the triplet representation should be ‘unique’ in the sense of `asUniqueT` (`byrow=FALSE`).

**Value**

A `list`, typically with three components,

`i` vector of row indices for all non-zero entries of `x`

`j` vector of columns indices for all non-zero entries of `x`

`x` vector of all non-zero entries of `x`; exists **only** when `as(x, "TsparseMatrix")` is **not** a `"nsparseMatrix"`.

Note that the `order` of the entries is determined by the coercion to `"TsparseMatrix"` and hence typically with increasing `j` (and increasing `i` within ties of `j`).

**Note**

The `mat2triplet()` utility was created to be a more efficient and more predictable substitute for `summary(<sparseMatrix>)`. UseRs have wrongly expected the latter to return a data frame with columns `i` and `j` which however is wrong for a `"diagonalMatrix"`.

**See Also**

The `summary()` method for `"sparseMatrix"`, `summary,sparseMatrix-method`.

`mat2triplet()` is conceptually the *inverse* function of `spMatrix` and (one case of) `sparseMatrix`.

**Examples**

```
mat2triplet # simple definition

i <- c(1,3:8); j <- c(2,9,6:10); x <- 7 * (1:7)
(Ax <- sparseMatrix(i, j, x = x)) ## 8 x 10 "dgCMatrix"
str(trA <- mat2triplet(Ax))
```

```
stopifnot(i == sort(trA$i), sort(j) == trA$j, x == sort(trA$x))

D <- Diagonal(x=4:2)
summary(D)
str(mat2triplet(D))
```

---

matmult-methods      *Matrix (Cross) Products (of Transpose)*

---

## Description

The basic matrix product, `%*%` is implemented for all our `Matrix` and also for `sparseVector` classes, fully analogously to R's base `matrix` and vector objects.

The functions `crossprod` and `tcrossprod` are matrix products or “cross products”, ideally implemented efficiently without computing `t(.)`'s unnecessarily. They also return `symmetricMatrix` classed matrices when easily detectable, e.g., in `crossprod(m)`, the one argument case.

`tcrossprod()` takes the cross-product of the transpose of a matrix. `tcrossprod(x)` is formally equivalent to, but faster than, the call `x %*% t(x)`, and so is `tcrossprod(x, y)` instead of `x %*% t(y)`.

*Boolean* matrix products are computed via either `%&%` or `boolArith = TRUE`.

## Usage

```
## S4 method for signature 'CsparseMatrix,diagonalMatrix'
x %*% y

## S4 method for signature 'CsparseMatrix,diagonalMatrix'
crossprod(x, y = NULL, boolArith = NA, ...)
## .... and for many more signatures

## S4 method for signature 'TsparseMatrix,missing'
tcrossprod(x, y = NULL, boolArith = NA, ...)
## .... and for many more signatures
```

## Arguments

|                        |  |
|------------------------|--|
| <code>x</code>         | a matrix-like object   |
| <code>y</code>         | a matrix-like object, or for <code>[t]crossprod()</code> <code>NULL</code> (by default); the latter case is formally equivalent to <code>y = x</code> .  |
| <code>boolArith</code> | <i>logical</i> , i.e., <code>NA</code> , <code>TRUE</code> , or <code>FALSE</code> . If true the result is (coerced to) a pattern matrix, i.e., <code>"nMatrix"</code> , unless there are <code>NA</code> entries and the result will be a <code>"lMatrix"</code> . If false the result is (coerced to) numeric. When <code>NA</code> , currently the default, the result is a pattern matrix when <code>x</code> and <code>y</code> are <code>"nsparseMatrix"</code> and numeric otherwise. |
| <code>...</code>       | potentially more arguments passed to and from methods.   |

## Details

For some classes in the `Matrix` package, such as `dgCMatrix`, it is much faster to calculate the cross-product of the transpose directly instead of calculating the transpose first and then its cross-product.

`boolArith = TRUE` for regular (“non cross”) matrix products, `%%` cannot be specified. Instead, we provide the `%&%` operator for *boolean* matrix products.

## Value

A `Matrix` object, in the one argument case of an appropriate *symmetric* matrix class, i.e., inheriting from `symmetricMatrix`.

## Methods

`%%` signature (`x = "dgeMatrix"`, `y = "dgeMatrix"`): `Matrix` multiplication; ditto for several other signature combinations, see `showMethods("%*", class = "dgeMatrix")`.

`%*%` signature (`x = "dtrMatrix"`, `y = "matrix"`) and other signatures (use `showMethods("%*%", class = "dtrMatrix")`): matrix multiplication. Multiplication of (matching) triangular matrices now should remain triangular (in the sense of class `triangularMatrix`).

**crossprod** signature (`x = "dgeMatrix"`, `y = "dgeMatrix"`): ditto for several other signatures, use `showMethods("crossprod", class = "dgeMatrix")`, matrix crossproduct, an efficient version of `t(x) %*% y`.

**crossprod** signature (`x = "CsparseMatrix"`, `y = "missing"`) returns `t(x) %*% x` as an `dsCMatrix` object.

**crossprod** signature (`x = "TsparseMatrix"`, `y = "missing"`) returns `t(x) %*% x` as an `dsCMatrix` object.

**crossprod, tcrossprod** signature (`x = "dtrMatrix"`, `y = "matrix"`) and other signatures, see `"%*%"` above.

## Note

`boolArith = TRUE, FALSE` or `NA` has been newly introduced for **Matrix** 1.2.0 (March 2015). Its implementation has still not been tested extensively. Notably the behaviour for sparse matrices with `x` slots containing extra zeros had not been documented previously, see the `%&%` help page.

Currently, `boolArith = TRUE` is implemented via `CsparseMatrix` coercions which may be quite inefficient for dense matrices. Contributions for efficiency improvements are welcome.

## See Also

`tcrossprod` in R’s base, and `crossprod` and `%%`. **Matrix** package `%&%` for boolean matrix product methods.

## Examples

```
## A random sparse "incidence" matrix :
m <- matrix(0, 400, 500)
set.seed(12)
m[runif(314, 0, length(m))] <- 1
mm <- as(m, "CsparseMatrix")
```

```

object.size(m) / object.size(mm) # smaller by a factor of > 200

## tcrossprod() is very fast:
system.time(tCmm <- tcrossprod(mm)) # 0      (PIII, 933 MHz)
system.time(cm <- crossprod(t(m))) # 0.16
system.time(cm. <- tcrossprod(m))  # 0.02

stopifnot(cm == as(tCmm, "matrix"))

## show sparse sub matrix
tCmm[1:16, 1:30]
```

Matrix

*Construct a Classed Matrix***Description**

Construct a Matrix of a class that inherits from Matrix.

**Usage**

```
Matrix(data=NA, nrow=1, ncol=1, byrow=FALSE, dimnames=NULL,
        sparse = NULL, doDiag = TRUE, forceCheck = FALSE)
```

**Arguments**

|                         |  |
|-------------------------|--|
| <code>data</code>       | an optional numeric data vector or matrix.   |
| <code>nrow</code>       | when data is not a matrix, the desired number of rows  |
| <code>ncol</code>       | when data is not a matrix, the desired number of columns   |
| <code>byrow</code>      | logical. If FALSE (the default) the matrix is filled by columns, otherwise the matrix is filled by rows.   |
| <code>dimnames</code>   | a <a href="#">dimnames</a> attribute for the matrix: a list of two character components. They are set if not <a href="#">NULL</a> (as per default).  |
| <code>sparse</code>     | logical or NULL, specifying if the result should be sparse or not. By default, it is made sparse when more than half of the entries are 0.   |
| <code>doDiag</code>     | logical indicating if a <a href="#">diagonalMatrix</a> object should be returned when the resulting matrix is diagonal ( <i>mathematically</i> ). As class <a href="#">diagonalMatrix</a> extends <a href="#">sparseMatrix</a> , this is a natural default for all values of <code>sparse</code> . Otherwise, if <code>doDiag</code> is false, a dense or sparse (depending on <code>sparse</code> ) <i>symmetric</i> matrix will be returned. |
| <code>forceCheck</code> | logical indicating if the checks for structure should even happen when data is already a "Matrix" object.  |

**Details**

If either of `nrow` or `ncol` is not given, an attempt is made to infer it from the length of `data` and the other parameter. Further, `Matrix()` makes efforts to keep [logical](#) matrices logical, i.e., inheriting from class [lMatrix](#), and to determine specially structured matrices such as symmetric, triangular or diagonal ones. Note that a *symmetric* matrix also needs symmetric [dimnames](#), e.g., by specifying `dimnames = list(NULL, NULL)`, see the examples.

Most of the time, the function works via a traditional (*full*) `matrix`. However, `Matrix(0, nrow, ncol)` directly constructs an “empty” `sparseMatrix`, as does `Matrix(FALSE, *)`.

Although it is sometime possible to mix unclassed matrices (created with `matrix`) with ones of class “`Matrix`”, it is much safer to always use carefully constructed ones of class “`Matrix`”.

### Value

Returns matrix of a class that inherits from “`Matrix`”. Only if data is not a `matrix` and does not already inherit from class `Matrix` are the arguments `nrow`, `ncol` and `byrow` made use of.

### See Also

The classes `Matrix`, `symmetricMatrix`, `triangularMatrix`, and `diagonalMatrix`; further, `matrix`.

Special matrices can be constructed, e.g., via `sparseMatrix` (sparse), `bdiag` (block-diagonal), `bandSparse` (banded sparse), or `Diagonal`.

### Examples

```
Matrix(0, 3, 2)           # 3 by 2 matrix of zeros -> sparse
Matrix(0, 3, 2, sparse=FALSE) # -> 'dense'

## 4 cases - 3 different results :
Matrix(0, 2, 2)           # diagonal !
Matrix(0, 2, 2, sparse=FALSE) # (ditto)
Matrix(0, 2, 2, doDiag=FALSE) # -> sparse symm. "dsCMatrix"
Matrix(0, 2, 2, sparse=FALSE, doDiag=FALSE) # -> dense symm. "dsyMatrix"

Matrix(1:6, 3, 2)         # a 3 by 2 matrix (+ integer warning)
Matrix(1:6 + 1, nrow=3)

## logical ones:
Matrix(diag(4) > 0) # -> "ldiMatrix" with diag = "U"
Matrix(diag(4) > 0, sparse=TRUE) # (ditto)
Matrix(diag(4) >= 0) # -> "lsyMatrix" (of all 'TRUE')
## triangular
l3 <- upper.tri(matrix(,3,3))
(M <- Matrix(l3)) # -> "ltCMatrix"
Matrix(! l3) # -> "ltrMatrix"
as(l3, "CsparseMatrix") # "lgCMatrix"

Matrix(1:9, nrow=3,
      dimnames = list(c("a", "b", "c"), c("A", "B", "C")))
(I3 <- Matrix(diag(3))) # identity, i.e., unit "diagonalMatrix"
str(I3) # note 'diag = "U"' and the empty 'x' slot

(A <- cbind(a=c(2,1), b=1:2)) # symmetric *apart* from dimnames
Matrix(A) # hence 'dgeMatrix'
(As <- Matrix(A, dimnames = list(NULL, NULL))) # -> symmetric
forceSymmetric(A) # also symmetric, w/ symm. dimnames
stopifnot(is(As, "symmetricMatrix"),
          is(Matrix(0, 3, 3), "sparseMatrix"),
          is(Matrix(FALSE, 1, 1), "sparseMatrix"))
```

## Description

The `Matrix` class is a class contained by all actual classes in the **Matrix** package. It is a “virtual” class.

## Slots

`Dim` an integer vector of length 2 giving the dimensions of the matrix.

`Dimnames` a list of length 2. Each element must be `NULL` or a character vector of length equal to the corresponding element of `Dim`.

## Methods

**determinant** signature(`x = "Matrix"`, `logarithm = "missing"`): and

**determinant** signature(`x = "Matrix"`, `logarithm = "logical"`): compute the (log) determinant of `x`. The method chosen depends on the actual `Matrix` class of `x`. Note that `det` also works for all our matrices, calling the appropriate `determinant()` method. The `Matrix::det` is an exact copy of `base::det`, but in the correct namespace, and hence calling the S4-aware version of `determinant()`.

**diff** signature(`x = "Matrix"`): As `diff()` for traditional matrices, i.e., applying `diff()` to each column.

**dim** signature(`x = "Matrix"`): extract matrix dimensions `dim`.

**dim<-** signature(`x = "Matrix"`, `value = "ANY"`): where `value` is integer of length 2. Allows to *reshape* `Matrix` objects, but only when `prod(value) == prod(dim(x))`.

**dimnames** signature(`x = "Matrix"`): extract `dimnames`.

**dimnames<-** signature(`x = "Matrix"`, `value = "list"`): set the `dimnames` to a `list` of length 2, see `dimnames<-`.

**length** signature(`x = "Matrix"`): simply defined as `prod(dim(x))` (and hence of mode "double").

**show** signature(`object = "Matrix"`): `show` method for `printing`. For printing *sparse* matrices, see `printSpMatrix`.

**zapsmall** signature(`x = "Matrix"`): typically used for "`dMatrix`": `round()` matrix entries such that (relatively) very small entries become zero exactly.

**image** signature(`object = "Matrix"`): draws an `image` of the matrix entries, using `levelplot()` from package **lattice**.

**head** signature(`object = "Matrix"`): return only the “*head*”, i.e., the first few rows.

**tail** signature(`object = "Matrix"`): return only the “*tail*”, i.e., the last few rows of the respective matrix.

**as.matrix, as.array** signature(`x = "Matrix"`): the same as `as(x, "matrix")`; see also the note below.

**as.vector** signature(`x = "Matrix"`, `mode = "missing"`): `as.vector(m)` should be identical to `as.vector(as(m, "matrix"))`, implemented more efficiently for some subclasses.

`as(x, "vector")`, `as(x, "numeric")` etc, similarly.

`coerce` signature(`from = "ANY"`, `to = "Matrix"`): This relies on a correct `as.matrix()` method for `from`.

There are many more methods that (conceptually should) work for all "Matrix" objects, e.g., `colSums`, `rowMeans`. Even **base** functions may work automatically (if they first call `as.matrix()` on their principal argument), e.g., `apply`, `eigen`, `svd` or `kappa` all do work via coercion to a “traditional” (dense) `matrix`.

### Note

Loading the `Matrix` namespace “overloads” `as.matrix` and `as.array` in the **base** namespace by the equivalent of `function(x) as(x, "matrix")`. Consequently, `as.matrix(m)` or `as.array(m)` will properly work when `m` inherits from the "Matrix" class — *also* for functions in package **base** and other packages. E.g., `apply` or `outer` can therefore be applied to "Matrix" matrices.

Douglas Bates <bates@stat.wisc.edu> and Martin Maechler

### See Also

the classes `dgeMatrix`, `dgCMatrix`, and function `Matrix` for construction (and examples).  
Methods, e.g., for `kronecker`.

### Examples

```
slotNames("Matrix")

cl <- getClass("Matrix")
names(cl@subclasses) # more than 40 ..

showClass("Matrix")#> output with slots and all subclasses

(M <- Matrix(c(0,1,0,0), 6, 4))
dim(M)
diag(M)
cm <- M[1:4,] + 10*Diagonal(4)
diff(M)
## can reshape it even :
dim(M) <- c(2, 12)
M
stopifnot(identical(M, Matrix(c(0,1,0,0), 2,12)),
           all.equal(det(cm),
                     determinant(as(cm,"matrix"), log=FALSE)$modulus,
                     check.attributes=FALSE))
```

Matrix-notyet

*Virtual Classes Not Yet Really Implemented and Used***Description**

`iMatrix` is the virtual class of all integer (S4) matrices. It extends the `Matrix` class directly.

`zMatrix` is the virtual class of all `complex` (S4) matrices. It extends the `Matrix` class directly.

**Examples**

```
showClass("iMatrix")
showClass("zMatrix")
```

MatrixClass

*The Matrix (Super-) Class of a Class***Description**

Return the (maybe super-) `class` of class `cl` from package **Matrix**, returning `character(0)` if there is none.

**Usage**

```
MatrixClass(cl, cld = getClassDef(cl), ...Matrix = TRUE,
            dropVirtual = TRUE, ...)
```

**Arguments**

|                          |   |
|--------------------------|---|
| <code>cl</code>          | string, class name  |
| <code>cld</code>         | its class definition  |
| <code>...Matrix</code>   | <code>logical</code> indicating if the result must be of pattern "[dlniz]..Matrix" where the first letter "[dlniz]" denotes the content kind. |
| <code>dropVirtual</code> | <code>logical</code> indicating if virtual classes are included or not.   |
| <code>...</code>         | further arguments are passed to <code>.selectSuperClasses()</code> .  |

**Value**

a `character` string

**Author(s)**

Martin Maechler, 24 Mar 2009

**See Also**

`Matrix`, the mother of all **Matrix** classes.

  MatrixClass("A"),
  "dgCMatrix"))
```

---

MatrixFactorization-class

*Virtual Class "MatrixFactorization" of Matrix Factorizations*

---

**Description**

MatrixFactorization is the virtual class of factorizations of  $m \times n$  matrices  $A$ , having the general form

$$P_1 A P_2 = A_1 \cdots A_p$$

or (equivalently)

$$A = P_1' A_1 \cdots A_p P_2'$$

where  $P_1$  and  $P_2$  are permutation matrices. Factorizations requiring symmetric  $A$  have the constraint  $P_2 = P_1'$ , and factorizations without row or column pivoting have the constraints  $P_1 = I_m$  and  $P_2 = I_n$ , where  $I_m$  and  $I_n$  are the  $m \times m$  and  $n \times n$  identity matrices.

CholeskyFactorization, BunchKaufmanFactorization,  
SchurFactorization, LU, and QR are the virtual subclasses of MatrixFactorization containing all Cholesky, Bunch-Kaufman, Schur, LU, and QR factorizations, respectively.

**Slots**

**Dim** an integer vector of length 2 giving the dimensions of the factorized matrix.

**Dimnames** a list of length 2 preserving the dimnames of the factorized matrix. Each element must be NULL or a character vector of length equal to the corresponding element of Dim.

**Methods**

```
determinant signature(x = "MatrixFactorization", logarithm =
  "missing"): sets logarithm = TRUE and recalls the generic function.
dim signature(x = "MatrixFactorization"): returns x@Dim.
dimnames signature(x = "MatrixFactorization"): returns x@Dimnames.
dimnames<- signature(x = "MatrixFactorization", value = "NULL"): returns
  x with x@Dimnames set to list(NULL, NULL).
dimnames<- signature(x = "MatrixFactorization", value = "list"): returns
  x with x@Dimnames set to value.
length signature(x = "MatrixFactorization"): returns prod(x@Dim).
show signature(object = "MatrixFactorization"): prints the internal representa-
  tion of the factorization using str.
solve signature(a = "MatrixFactorization", b = .): see solve-methods.
unname signature(obj = "MatrixFactorization"): returns obj with
  obj@Dimnames set to list(NULL, NULL).
```

```

---

ndenseMatrix-class *Virtual Class "ndenseMatrix" of Dense Logical Matrices*

---

**Description**

ndenseMatrix is the virtual class of all dense logical (S4) matrices. It extends both [denseMatrix](#) and [lMatrix](#) directly.

**Slots**

**x:** logical vector containing the entries of the matrix.

**Dim, Dimnames:** see [Matrix](#).

**Extends**

Class "nMatrix", directly. Class "denseMatrix", directly. Class "Matrix", by class "nMatrix". Class "Matrix", by class "denseMatrix".

**Methods**

**%\*%** signature(x = "nsparseMatrix", y = "ndenseMatrix"): ...

**%\*%** signature(x = "ndenseMatrix", y = "nsparseMatrix"): ...

**crossprod** signature(x = "nsparseMatrix", y = "ndenseMatrix"): ...

**crossprod** signature(x = "ndenseMatrix", y = "nsparseMatrix"): ...

**as.vector** signature(x = "ndenseMatrix", mode = "missing"): ...

**diag** signature(x = "ndenseMatrix"): extracts the diagonal as for all matrices, see the generic [diag\(\)](#).

**which** signature(x = "ndenseMatrix"), semantically equivalent to **base** function [which](#)(x, arr.ind); for details, see the [lMatrix](#) class documentation.

## See Also

Class [ngeMatrix](#) and the other subclasses.

## Examples

```
showClass("ndenseMatrix")

as(diag(3) > 0, "ndenseMatrix")# -> "nge"
```

---

|        |   |
|--------|---|
| nearPD | <i>Nearest Positive Definite Matrix</i> |
|--------|---|

---

## Description

Compute the nearest positive definite matrix to an approximate one, typically a correlation or variance-covariance matrix.

## Usage

```
nearPD(x, corr = FALSE, keepDiag = FALSE, base.matrix = FALSE,
       do2eigen = TRUE, doSym = FALSE,
       doDykstra = TRUE, only.values = FALSE,
       ensureSymmetry = !isSymmetric(x),
       eig.tol = 1e-06, conv.tol = 1e-07, posd.tol = 1e-08,
       maxit = 100, conv.norm.type = "I", trace = FALSE)
```

## Arguments

|                             |  |
|-----------------------------|--|
| <code>x</code>              | numeric $n \times n$ approximately positive definite matrix, typically an approximation to a correlation or covariance matrix. If <code>x</code> is not symmetric (and <code>ensureSymmetry</code> is not false), <a href="#">symmpart</a> ( <code>x</code> ) is used.   |
| <code>corr</code>           | logical indicating if the matrix should be a <i>correlation</i> matrix.  |
| <code>keepDiag</code>       | logical, generalizing <code>corr</code> : if TRUE, the resulting matrix should have the same diagonal ( <a href="#">diag</a> ( <code>x</code> )) as the input matrix.  |
| <code>base.matrix</code>    | logical indicating if the resulting <code>mat</code> component should be a <b>base matrix</b> or (by default) a <a href="#">Matrix</a> of class <a href="#">dpoMatrix</a> .  |
| <code>do2eigen</code>       | logical indicating if a <a href="#">posdefify</a> () eigen step should be applied to the result of the Higham algorithm.   |
| <code>doSym</code>          | logical indicating if <code>X &lt;- (X + t(X))/2</code> should be done, after <code>X &lt;- tcrossprod(Qd, Q)</code> ; some doubt if this is necessary.  |
| <code>doDykstra</code>      | logical indicating if Dykstra's correction should be used; true by default. If false, the algorithm is basically the direct fixpoint iteration $Y_k = P_U(P_S(Y_{k-1}))$ .   |
| <code>only.values</code>    | logical; if TRUE, the result is just the vector of eigenvalues of the approximating matrix.  |
| <code>ensureSymmetry</code> | logical; by default, <a href="#">symmpart</a> ( <code>x</code> ) is used whenever <a href="#">isSymmetric</a> ( <code>x</code> ) is not true. The user can explicitly set this to TRUE or FALSE, saving the symmetry test. <i>Beware</i> however that setting it FALSE for an asymmetric input <code>x</code> , is typically nonsense! |

|                             |   |
|-----------------------------|---|
| <code>eig.tol</code>        | defines relative positiveness of eigenvalues compared to largest one, $\lambda_1$ . Eigenvalues $\lambda_k$ are treated as if zero when $\lambda_k/\lambda_1 \leq \text{eig.tol}$ .                             |
| <code>conv.tol</code>       | convergence tolerance for Higham algorithm.   |
| <code>posd.tol</code>       | tolerance for enforcing positive definiteness (in the final <code>posdefify</code> step when <code>do2eigen</code> is TRUE).  |
| <code>maxit</code>          | maximum number of iterations allowed.   |
| <code>conv.norm.type</code> | convergence norm type ( <code>norm(*, type)</code> ) used for Higham algorithm. The default is "I" (infinity), for reasons of speed (and back compatibility); using "F" is more in line with Higham's proposal. |
| <code>trace</code>          | logical or integer specifying if convergence monitoring should be traced.   |

### Details

This implements the algorithm of Higham (2002), and then (if `do2eigen` is true) forces positive definiteness using code from `posdefify`. The algorithm of Knol and ten Berge (1989) (not implemented here) is more general in that it allows constraints to (1) fix some rows (and columns) of the matrix and (2) force the smallest eigenvalue to have a certain value.

Note that setting `corr = TRUE` just sets `diag(.) <- 1` within the algorithm.

Higham (2002) uses Dykstra's correction, but the version by Jens Oehlschlägel did not use it (accidentally), and still gave reasonable results; this simplification, now only used if `doDykstra = FALSE`, was active in `nearPD()` up to Matrix version 0.999375-40.

### Value

If `only.values = TRUE`, a numeric vector of eigenvalues of the approximating matrix; Otherwise, as by default, an S3 object of class `"nearPD"`, basically a list with components

|                          |   |
|--------------------------|---|
| <code>mat</code>         | a matrix of class <code>dpoMatrix</code> , the computed positive-definite matrix.                                   |
| <code>eigenvalues</code> | numeric vector of eigenvalues of <code>mat</code> .   |
| <code>corr</code>        | logical, just the argument <code>corr</code> .  |
| <code>normF</code>       | the Frobenius norm ( <code>norm(x-X, "F")</code> ) of the difference between the original and the resulting matrix. |
| <code>iterations</code>  | number of iterations needed.  |
| <code>converged</code>   | logical indicating if iterations converged.   |

### Author(s)

Jens Oehlschlägel donated a first version. Subsequent changes by the Matrix package authors.

A first version of this (with non-optional `corr=TRUE`) has been available as `nearcor()`; and more simple versions with a similar purpose `posdefify()`, both from package **sfsmisc**.

## Examples

```
## Higham(2002), p.334f - simple example
A <- matrix(1, 3,3); A[1,3] <- A[3,1] <- 0
n.A <- nearPD(A, corr=TRUE, do2eigen=FALSE)
n.A[c("mat", "normF")]
n.A.m <- nearPD(A, corr=TRUE, do2eigen=FALSE, base.matrix=TRUE)$mat
stopifnot(exprs = { #=====
  all.equal(n.A$mat[1,2], 0.760689917)
  all.equal(n.A$normF, 0.52779033, tolerance=1e-9)
  all.equal(n.A.m, unname(as.matrix(n.A$mat)), tolerance = 1e-15) # seen rel.d.= 1.46e-16
})
set.seed(27)
m <- matrix(round(rnorm(25),2), 5, 5)
m <- m + t(m)
diag(m) <- pmax(0, diag(m)) + 1
(m <- round(cov2cor(m), 2))

str(near.m <- nearPD(m, trace = TRUE))
round(near.m$mat, 2)
norm(m - near.m$mat) # 1.102 / 1.08

if(requireNamespace("sfsmisc")) {
  m2 <- sfsmisc::posdefify(m) # a simpler approach
  norm(m - m2) # 1.185, i.e., slightly "less near"
}

round(nearPD(m, only.values=TRUE), 9)

## A longer example, extended from Jens' original,
## showing the effects of some of the options:

pr <- Matrix(c(1,      0.477, 0.644, 0.478, 0.651, 0.826,
               0.477, 1,      0.516, 0.233, 0.682, 0.75,
               0.644, 0.516, 1,      0.599, 0.581, 0.742,
               0.478, 0.233, 0.599, 1,      0.741, 0.8,
               0.651, 0.682, 0.581, 0.741, 1,      0.798,
               0.826, 0.75,  0.742, 0.8,    0.798, 1),
             nrow = 6, ncol = 6)

nc. <- nearPD(pr, conv.tol = 1e-7) # default
nc.$iterations # 2
nc.l <- nearPD(pr, conv.tol = 1e-7, corr = TRUE)
nc.l$iterations # 11 / 12 (!)
ncr <- nearPD(pr, conv.tol = 1e-15)
str(ncr) # still 2 iterations
ncr.l <- nearPD(pr, conv.tol = 1e-15, corr = TRUE)
ncr.l $ iterations # 27 / 30 !

ncF <- nearPD(pr, conv.tol = 1e-15, conv.norm = "F")
stopifnot(all.equal(ncr, ncF)) # norm type does not matter at all in this example
```

```
## But indeed, the 'corr = TRUE' constraint did ensure a better solution;
## cov2cor() does not just fix it up equivalently :
norm(pr - cov2cor(ncr$mat)) # = 0.09994
norm(pr -          ncr.l$mat) # = 0.08746 / 0.08805

### 3) a real data example from a 'systemfit' model (3 eq.):
(load(system.file("external", "symW.rda", package="Matrix"))) # "symW"
dim(symW) # 24 x 24
class(symW) # "dsCMatrix": sparse symmetric
if(dev.interactive()) image(symW)
EV <- eigen(symW, only=TRUE)$values
summary(EV) ## looking more closely {EV sorted decreasingly}:
tail(EV) # all 6 are negative
EV2 <- eigen(sWpos <- nearPD(symW)$mat, only=TRUE)$values
stopifnot(EV2 > 0)
if(requireNamespace("sfsmisc")) {
  plot(pmax(1e-3,EV), EV2, type="o", log="xy", xaxt="n", yaxt="n")
  for(side in 1:2) sfsmisc::eaxis(side)
} else
  plot(pmax(1e-3,EV), EV2, type="o", log="xy")
abline(0, 1, col="red3", lty=2)
```

ngeMatrix-class

*Class "ngeMatrix" of General Dense Nonzero-pattern Matrices*

## Description

This is the class of general dense nonzero-pattern matrices, see [nMatrix](#).

## Slots

- x:** Object of class "logical". The logical values that constitute the matrix, stored in column-major order.
- Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#) class.
- factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

## Extends

Class "ndenseMatrix", directly. Class "lMatrix", by class "ndenseMatrix".  
 Class "denseMatrix", by class "ndenseMatrix". Class "Matrix", by class  
 "ndenseMatrix". Class "Matrix", by class "ndenseMatrix".

## Methods

Currently, mainly `t()` and coercion methods (for `as(.)`); use, e.g.,  
[showMethods](#)(class="ngeMatrix") for details.

## See Also

Non-general logical dense matrix classes such as [ntrMatrix](#), or [nsyMatrix](#); *sparse* logical classes such as [ngCMatrix](#).

**Examples**

```
showClass("ngeMatrix")
## "lgeMatrix" is really more relevant
```

---

nMatrix-class

*Class "nMatrix" of Non-zero Pattern Matrices*

---

**Description**

The `nMatrix` class is the virtual “mother” class of all *non-zero pattern* (or simply *pattern*) matrices in the **Matrix** package.

**Slots**

Common to *all* matrix object in the package:

**Dim:** Object of class `"integer"` - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

**Dimnames:** list of length two; each component containing `NULL` or a `character` vector length equal the corresponding `Dim` element.

**Methods**

**coerce** signature(`from` = `"matrix"`, `to` = `"nMatrix"`): Note that these coercions (must) coerce `NAs` to non-zero, hence conceptually `TRUE`. This is particularly important when `sparseMatrix` objects are coerced to `"nMatrix"` and hence to `nsparseMatrix`.

— — —

Additional methods contain group methods, such as

**Ops** signature(`e1` = `"nMatrix"`, `e2` = `"...."`),...

**Arith** signature(`e1` = `"nMatrix"`, `e2` = `"...."`),...

**Compare** signature(`e1` = `"nMatrix"`, `e2` = `"...."`),...

**Logic** signature(`e1` = `"nMatrix"`, `e2` = `"...."`),...

**Summary** signature(`x` = `"nMatrix"`, `"...."`),...

**See Also**

The classes `lMatrix`, `nsparseMatrix`, and the mother class, `Matrix`.

**Examples**

```
getClass("nMatrix")

L3 <- Matrix(upper.tri(diag(3)))
L3 # an "ltCMatrix"
as(L3, "nMatrix") # -> ntC*

## similar, not using Matrix()
as(upper.tri(diag(3)), "nMatrix") # currently "ngTMatrix"
```

**Description**

Returns the number of non-zero values of a numeric-like R object, and in particular an object `x` inheriting from class `Matrix`.

**Usage**

```
nnzero(x, na.counted = NA)
```

**Arguments**

`x` an R object, typically inheriting from class `Matrix` or `numeric`.

`na.counted` a `logical` describing how `NA`s should be counted. There are three possible settings for `na.counted`:

**TRUE** `NA`s are counted as non-zero (since “they are not zero”).

**NA** (default) the result will be `NA` if there are `NA`’s in `x` (since “`NA`’s are not known, i.e., *may be* zero”).

**FALSE** `NA`s are *omitted* from `x` before the non-zero entries are counted.

For sparse matrices, you may often want to use `na.counted = TRUE`.

**Value**

the number of non zero entries in `x` (typically `integer`).

Note that for a *symmetric* sparse matrix `S` (i.e., inheriting from class `symmetricMatrix`), `nnzero(S)` is typically *twice* the `length(S@x)`.

**Methods**

`signature(x = "ANY")` the default method for non-`Matrix` class objects, simply counts the number 0s in `x`, counting `NA`’s depending on the `na.counted` argument, see above.

`signature(x = "denseMatrix")` conceptually the same as for traditional `matrix` objects, care has to be taken for `"symmetricMatrix"` objects.

`signature(x = "diagonalMatrix")`, **and** `signature(x = "indMatrix")` fast simple methods for these special `"sparseMatrix"` classes.

`signature(x = "sparseMatrix")` typically, the most interesting method, also carefully taking `"symmetricMatrix"` objects into account.

**See Also**

The `Matrix` class also has a `length` method; typically, `length(M)` is much larger than `nnzero(M)` for a sparse matrix `M`, and the latter is a better indication of the *size* of `M`.

`drop0`, `zapsmall`.

**Examples**

```

m <- Matrix(0+1:28, nrow = 4)
m[-3,c(2,4:5,7)] <- m[ 3, 1:4] <- m[1:3, 6] <- 0
(mT <- as(m, "TsparseMatrix"))
nnzero(mT)
(S <- crossprod(mT))
nnzero(S)
str(S) # slots are smaller than nnzero()
stopifnot(nnzero(S) == sum(as.matrix(S) != 0)) # failed earlier

data(KNex, package = "Matrix")
M <- KNex$mm
class(M)
dim(M)
length(M); stopifnot(length(M) == prod(dim(M)))
nnzero(M) # more relevant than length
## the above are also visible from
str(M)

```

norm-methods

*Matrix Norms***Description**

Computes a matrix norm of `x`, using Lapack for dense matrices. The norm can be the one ("O", or "1") norm, the infinity ("I") norm, the Frobenius ("F") norm, the maximum modulus ("M") among elements of a matrix, or the spectral norm or 2-norm ("2"), as determined by the value of `type`.

**Usage**

```
norm(x, type, ...)
```

**Arguments**

|                   |  |
|-------------------|--|
| <code>x</code>    | a real or complex matrix.  |
| <code>type</code> | A character indicating the type of norm desired.<br>"O", "o" or "1" specifies the one norm, (maximum absolute column sum);<br>"I" or "i" specifies the infinity norm (maximum absolute row sum);<br>"F" or "f" specifies the Frobenius norm (the Euclidean norm of <code>x</code> treated as if it were a vector);<br>"M" or "m" specifies the maximum modulus of all the elements in <code>x</code> ; and<br>"2" specifies the “spectral norm” aka “2-norm”, which is the largest singular value ( <a href="#">svd</a> ) of <code>x</code> .<br>The default is "O". Only the first character of <code>type[1]</code> is used. |
| <code>...</code>  | further arguments passed to or from other methods.   |

**Details**

For dense matrices, the methods eventually call the Lapack functions `dlange`, `dlansy`, `dlantr`, `zlange`, `zlansy`, and `zlantr`.

**Value**

A numeric value of class "norm", representing the quantity chosen according to type.

**References**

Anderson, E., et al. (1994). *LAPACK User's Guide*, 2nd edition, SIAM, Philadelphia.

**See Also**

`onenormest()`, an *approximate* randomized estimate of the 1-norm condition number, efficient for large sparse matrices.

The `norm()` function from R's **base** package.

**Examples**

```
x <- Hilbert(9)
norm(x) # = "O" = "1"
stopifnot(identical(norm(x), norm(x, "1")))
norm(x, "I") # the same, because 'x' is symmetric

allnorms <- function(x) {
  ## norm(NA, "2") did not work until R 4.0.0
  do2 <- getRversion() >= "4.0.0" || !anyNA(x)
  vapply(c("1", "I", "F", "M", if(do2) "2"), norm, 0, x = x)
}
allnorms(x)
allnorms(Hilbert(10))

i <- c(1,3:8); j <- c(2,9,6:10); x <- 7 * (1:7)
A <- sparseMatrix(i, j, x = x) ## 8 x 10 "dgCMatrix"
(sA <- sparseMatrix(i, j, x = x, symmetric = TRUE)) ## 10 x 10 "dsCMatrix"
(tA <- sparseMatrix(i, j, x = x, triangular = TRUE)) ## 10 x 10 "dtCMatrix"
(allnorms(A) -> nA)
allnorms(sA)
allnorms(tA)
stopifnot(all.equal(nA, allnorms(as(A, "matrix"))),
  all.equal(nA, allnorms(tA))) # because tA == rbind(A, 0, 0)
A. <- A; A.[1,3] <- NA
stopifnot(is.na(allnorms(A.))) # gave error
```

---

nsparseMatrix-class

*Sparse "pattern" Matrices*

---

**Description**

The `nsparseMatrix` class is a virtual class of sparse “*pattern*” matrices, i.e., binary matrices conceptually with TRUE/FALSE entries. Only the positions of the elements that are TRUE are stored.

These can be stored in the “triplet” form (`TsparseMatrix`, subclasses `ngTMatrix`, `nsTMatrix`, and `ntTMatrix` which really contain pairs, not triplets) or in compressed column-oriented form (class `CsparseMatrix`, subclasses `ngCMatrix`, `nsCMatrix`, and

ntCMatrix) or—rarely—in compressed row-oriented form (class [RsparseMatrix](#), subclasses [ngRMatrix](#), [nsRMatrix](#), and [ntRMatrix](#)). The second letter in the name of these non-virtual classes indicates general, symmetric, or triangular.

### Objects from the Class

Objects can be created by calls of the form `new("ngCMatrix", ...)` and so on. More frequently objects are created by coercion of a numeric sparse matrix to the pattern form for use in the symbolic analysis phase of an algorithm involving sparse matrices. Such algorithms often involve two phases: a symbolic phase wherein the positions of the non-zeros in the result are determined and a numeric phase wherein the actual results are calculated. During the symbolic phase only the positions of the non-zero elements in any operands are of interest, hence numeric sparse matrices can be treated as sparse pattern matrices.

### Slots

- uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular. Present in the triangular and symmetric classes but not in the general class.
- diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N" for non-unit. The implicit diagonal elements are not explicitly stored when diag is "U". Present in the triangular classes only.
- p:** Object of class "integer" of pointers, one for each column (row), to the initial (zero-based) index of elements in the column. Present in compressed column-oriented and compressed row-oriented forms only.
- i:** Object of class "integer" of length nnzero (number of non-zero elements). These are the row numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed column-oriented forms only.
- j:** Object of class "integer" of length nnzero (number of non-zero elements). These are the column numbers for each TRUE element in the matrix. All other elements are FALSE. Present in triplet and compressed row-oriented forms only.
- Dim:** Object of class "integer" - the dimensions of the matrix.

### Methods

**coerce** signature (from = "dgCMatrix", to = "ngCMatrix"), and many similar ones; typically you should coerce to "nsparseMatrix" (or "nMatrix"). Note that coercion to a sparse pattern matrix records all the potential non-zero entries, i.e., explicit ("non-structural") zeroes are coerced to TRUE, not FALSE, see the example.

**t** signature (x = "ngCMatrix"): returns the transpose of x

**which** signature (x = "lsparseMatrix"), semantically equivalent to **base** function `which(x, arr.ind)`; for details, see the [lMatrix](#) class documentation.

### See Also

the class [dgCMatrix](#)

### Examples

```
(m <- Matrix(c(0,0,2:0), 3,5, dimnames=list(LETTERS[1:3],NULL)))
## ``extract the nonzero-pattern of (m) into an nMatrix``:
nm <- as(m, "nsparseMatrix") ## -> will be a "ngCMatrix"
str(nm) # no 'x' slot
```

```

nnm <- !nm # no longer sparse
## consistency check:
stopifnot(xor(as( nm, "matrix"),
               as(nnm, "matrix")))

## low-level way of adding "non-structural zeros" :
nnm <- as(nnm, "lsparseMatrix") # "lgCMatrix"
nnm@x[2:4] <- c(FALSE, NA, NA)
nnm
as(nnm, "nMatrix") # NAs *and* non-structural 0 |---> 'TRUE'

data(KNex, package = "Matrix")
nmm <- as(KNex $ mm, "nMatrix")
str(xlx <- crossprod(nmm)) # "nsCMatrix"
stopifnot(isSymmetric(xlx))
image(xlx, main=paste("crossprod(nmm) : Sparse", class(xlx)))

```

---

nsyMatrix-class      *Symmetric Dense Nonzero-Pattern Matrices*

---

## Description

The "nsyMatrix" class is the class of symmetric, dense nonzero-pattern matrices in non-packed storage and "nspMatrix" is the class of these in packed storage. Only the upper triangle or the lower triangle is stored.

## Objects from the Class

Objects can be created by calls of the form `new("nsyMatrix", ...)`.

## Slots

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**x:** Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

**Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#) class.

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

## Extends

"nsyMatrix" extends class "ngeMatrix", directly, whereas  
 "nspMatrix" extends class "ndenseMatrix", directly.

Both extend class "symmetricMatrix", directly, and class "Matrix" and others, *indirectly*, use `showClass("nsyMatrix")`, e.g., for details.

## Methods

Currently, mainly `t()` and coercion methods (for `as(.)`; use, e.g., `showMethods(class="nsyMatrix")` for details.

**See Also**

[ngeMatrix](#), [Matrix](#), [t](#)

**Examples**

```
(s0 <- new("nsyMatrix"))

(M2 <- Matrix(c(TRUE, NA, FALSE, FALSE), 2, 2)) # logical dense (ltr)
(sM <- M2 & t(M2))                               # -> "lge"
class(sM <- as(sM, "nMatrix"))                     # -> "nge"
      (sM <- as(sM, "symmetricMatrix"))             # -> "nsy"
str(sM <- as(sM, "packedMatrix")) # -> "nsp", i.e., packed symmetric
```

---

|                 |  |
|-----------------|--|
| ntrMatrix-class | <i>Triangular Dense Logical Matrices</i> |
|-----------------|--|

---

**Description**

The "ntrMatrix" class is the class of triangular, dense, logical matrices in nonpacked storage. The "ntpMatrix" class is the same except in packed storage.

**Slots**

**x:** Object of class "logical". The logical values that constitute the matrix, stored in column-major order.

**uplo:** Object of class "character". Must be either "U", for upper triangular, and "L", for lower triangular.

**diag:** Object of class "character". Must be either "U", for unit triangular (diagonal is all ones), or "N"; see [triangularMatrix](#).

**Dim,Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), see the [Matrix](#) class.

**factors:** Object of class "list". A named list of factorizations that have been computed for the matrix.

**Extends**

"ntrMatrix" extends class "ngeMatrix", directly, whereas

"ntpMatrix" extends class "ndenseMatrix", directly.

Both extend Class "triangularMatrix", directly, and class "denseMatrix", "lMatrix" and others, *indirectly*, use [showClass](#)("nsyMatrix"), e.g., for details.

**Methods**

Currently, mainly [t\(\)](#) and coercion methods (for [as\(.\)](#); use, e.g., [showMethods](#)(class="ntrMatrix") for details.

**See Also**

Classes [ngeMatrix](#), [Matrix](#); function [t](#)

## Examples

```
showClass("ntrMatrix")

str(new("ntpMatrix"))
(nutr <- as(upper.tri(matrix(, 4, 4)), "ndenseMatrix"))
str(nutp <- pack(nutr)) # packed matrix: only 10 = 4*(4+1)/2 entries
!nutp # the logical negation (is *not* logical triangular !)
## but this one is:
stopifnot(all.equal(nutp, pack(!!nutp)))
```

---

pack-methods

---

*Representation of Packed and Unpacked Dense Matrices*

---

## Description

`pack()` coerces dense symmetric and dense triangular matrices from unpacked format (storing the full matrix) to packed format (storing only one of the upper and lower triangles). `unpack()` performs the reverse coercion. The two formats are formalized by the virtual classes `"packedMatrix"` and `"unpackedMatrix"`.

## Usage

```
pack(x, ...)
## S4 method for signature 'dgeMatrix'
pack(x, symmetric = NA, upperTri = NA, ...)
## S4 method for signature 'lgeMatrix'
pack(x, symmetric = NA, upperTri = NA, ...)
## S4 method for signature 'ngeMatrix'
pack(x, symmetric = NA, upperTri = NA, ...)
## S4 method for signature 'matrix'
pack(x, symmetric = NA, upperTri = NA, ...)

unpack(x, ...)
```

## Arguments

|                        |  |
|------------------------|--|
| <code>x</code>         | A dense symmetric or dense triangular matrix.<br><b>For</b> <code>pack()</code> : typically an <code>"unpackedMatrix"</code> or a standard <code>"matrix"</code> , though <code>"packedMatrix"</code> are allowed and returned unchanged.<br><b>For</b> <code>unpack()</code> : typically a <code>"packedMatrix"</code> , though <code>"unpackedMatrix"</code> are allowed and returned unchanged. |
| <code>symmetric</code> | logical (including NA) optionally indicating whether <code>x</code> is symmetric (or triangular).  |
| <code>upperTri</code>  | (for triangular <code>x</code> only) logical (including NA) indicating whether <code>x</code> is upper (or lower) triangular.  |
| <code>...</code>       | further arguments passed to or from other methods.   |

## Details

`pack(x)` checks matrices  $x$  *not* inheriting from one of the virtual classes "`symmetricMatrix`" "`triangularMatrix`" for symmetry (via `isSymmetric()`) then for upper and lower triangularity (via `isTriangular()`) in order to identify a suitable coercion. Setting one or both of `symmetric` and `upperTri` to `TRUE` or `FALSE` rather than `NA` allows skipping of irrelevant tests for large matrices known to be symmetric or (upper or lower) triangular.

Users should *not* assume that `pack()` and `unpack()` are inverse operations. Specifically, `y <- unpack(pack(x))` may not reproduce an "`unpackedMatrix`"  $x$  in the sense of `identical()`. See the examples.

## Value

**For** `pack()`: a "`packedMatrix`" giving the condensed representation of  $x$ .

**For** `unpack()`: an "`unpackedMatrix`" giving the full storage representation of  $x$ .

## Examples

```
showMethods("pack")
(s <- crossprod(matrix(sample(15), 5,3))) # traditional symmetric matrix
(sp <- pack(s))
mt <- as.matrix(tt <- tril(s))
(pt <- pack(mt))
stopifnot(identical(pt, pack(tt)),
  dim(s) == dim(sp), all(s == sp),
  dim(mt) == dim(pt), all(mt == pt), all(mt == tt))

showMethods("unpack")
(cp4 <- chol(Hilbert(4))) # is triangular
tp4 <- pack(cp4) # [t]riangular [p]acked
str(tp4)
(unpack(tp4))
stopifnot(identical(tp4, pack(unpack(tp4))))

z1 <- new("dsyMatrix", Dim = c(2L, 2L), x = as.double(1:4), uplo = "U")
z2 <- unpack(pack(z1))
stopifnot(!identical(z1, z2), # _not_ identical
  all(z1 == z2)) # but mathematically equal
cbind(z1@x, z2@x) # (unused!) lower triangle is "lost" in translation
```

---

packedMatrix-class *Virtual Class "packedMatrix" of Packed Dense Matrices*

---

## Description

Class "`packedMatrix`" is the *virtual* class of dense symmetric or triangular matrices in "packed" format, storing only the  $\text{choose}(n+1, 2) = n*(n+1)/2$  elements of the upper or lower triangle of an  $n$ -by- $n$  matrix. It is used to define common methods for efficient subsetting, transposing, etc. of its *proper* subclasses: currently "`[dln]spMatrix`" (packed symmetric), "`[dln]tpMatrix`" (packed triangular), and subclasses of these, such as "`dppMatrix`".

**Slots**

`uplo`: "character"; either "U", for upper triangular, and "L", for lower.

`Dim`, `Dimnames`: as all `Matrix` objects.

**Extends**

Class "`denseMatrix`", directly. Class "`Matrix`", by class "`denseMatrix`", distance 2.

**Methods**

**pack** signature (x = "packedMatrix"): ...

**unpack** signature (x = "packedMatrix"): ...

**isSymmetric** signature (object = "packedMatrix"): ...

**isTriangular** signature (object = "packedMatrix"): ...

**isDiagonal** signature (object = "packedMatrix"): ...

**t** signature (x = "packedMatrix"): ...

**diag** signature (x = "packedMatrix"): ...

**diag<-** signature (x = "packedMatrix"): ...

**Author(s)**

Mikael Jagan

**See Also**

`pack` and `unpack`; its virtual "complement" "`unpackedMatrix`"; its proper subclasses "`dspMatrix`", "`ltpMatrix`", etc.

**Examples**

```
showClass("packedMatrix")
showMethods(classes = "packedMatrix")
```

---

pMatrix-class

*Permutation matrices*

---

**Description**

The `pMatrix` class is the class of *permutation* matrices, stored as 1-based integer permutation vectors. A permutation matrix is a square matrix whose rows *and* columns are all standard unit vectors. It follows that permutation matrices are a special case of *index* matrices (hence `pMatrix` is defined as a direct subclass of `indMatrix`).

Multiplying a matrix on the left by a permutation matrix is equivalent to permuting its rows. Analogously, multiplying a matrix on the right by a permutation matrix is equivalent to permuting its columns. Indeed, such products are implemented in **Matrix** as indexing operations; see ‘Details’ below.

## Details

By definition, a permutation matrix is both a row index matrix and a column index matrix. However, the `perm` slot of a `pMatrix` cannot be used interchangeably as a row index vector and column index vector. If `margin=1`, then `perm` is a row index vector, and the corresponding column index vector can be computed as `invPerm(perm)`, i.e., by inverting the permutation. Analogously, if `margin=2`, then `perm` and `invPerm(perm)` are column and row index vectors, respectively.

Given an  $n$ -by- $n$  row permutation matrix  $P$  with `perm` slot  $p$  and a matrix  $M$  with conformable dimensions, we have

$$\begin{array}{llll}
 PM & = & P \%*\% M & = & M[p, ] \\
 MP & = & M \%*\% P & = & M[, i(p)] \\
 P'M & = & \text{crossprod}(P, M) & = & M[i(p), ] \\
 MP' & = & \text{tcrossprod}(M, P) & = & M[, p] \\
 P'P & = & \text{crossprod}(P) & = & \text{Diagonal}(n) \\
 PP' & = & \text{tcrossprod}(P) & = & \text{Diagonal}(n)
 \end{array}$$

where  $i := \text{invPerm}$ .

## Objects from the Class

Objects can be created explicitly with calls of the form `new("pMatrix", ...)`, but they are more commonly created by coercing 1-based integer index vectors, with calls of the form `as(., "pMatrix")`; see ‘Methods’ below.

## Slots

`margin, perm` inherited from superclass `indMatrix`. Here, `perm` is an integer vector of length `Dim[1]` and a permutation of `1:Dim[1]`.

`Dim, Dimnames` inherited from virtual superclass `Matrix`.

## Extends

Class `"indMatrix"`, directly.

## Methods

`%%` signature (`x = "pMatrix"`, `y = "Matrix"`) and others listed by `showMethods("%%", classes = "pMatrix")`: matrix products implemented where appropriate as indexing operations.

`coerce` signature (`from = "numeric"`, `to = "pMatrix"`): supporting typical `pMatrix` construction from a vector of positive integers, specifically a permutation of `1:n`. Row permutation is assumed.

`t` signature (`x = "pMatrix"`): the transpose, which is a `pMatrix` with identical `perm` but opposite `margin`. Coincides with the inverse, as permutation matrices are orthogonal.

`solve` signature (`a = "pMatrix"`, `b = "missing"`): the inverse permutation matrix, which is a `pMatrix` with identical `perm` but opposite `margin`. Coincides with the transpose, as permutation matrices are orthogonal. See `showMethods("solve", classes = "pMatrix")` for more signatures.

`determinant` signature (`x = "pMatrix"`, `logarithm = "logical"`): always returning 1 or -1, as permutation matrices are orthogonal. In fact, the result is exactly the *sign* of the permutation.

**See Also**

Superclass [indMatrix](#) of index matrices, for many inherited methods; [invPerm](#), for computing inverse permutation vectors.

**Examples**

```
(pml <- as(as.integer(c(2,3,1)), "pMatrix"))
t(pml) # is the same as
solve(pml)
pml %*% t(pml) # check that the transpose is the inverse
stopifnot(all(diag(3) == as(pml %*% t(pml), "matrix")),
           is.logical(as(pml, "matrix")))

set.seed(11)
## random permutation matrix :
(pl0 <- as(sample(10), "pMatrix"))

## Permute rows / columns of a numeric matrix :
(mm <- round(array(rnorm(3 * 3), c(3, 3)), 2))
mm %*% pml
pml %*% mm
try(as(as.integer(c(3,3,1)), "pMatrix"))# Error: not a permutation

as(pml, "TsparseMatrix")
pl0[1:7, 1:4] # gives an "ngTMatrix" (most economic!)

## row-indexing of a <pMatrix> keeps it as an <indMatrix>:
pl0[1:3, ]
```

---

printSpMatrix

---

*Format and Print Sparse Matrices Flexibly*

---

**Description**

Format and print sparse matrices flexibly. These are the “workhorses” used by the [format](#), [show](#) and [print](#) methods for sparse matrices. If *x* is large, `printSpMatrix2(x)` calls `printSpMatrix()` twice, namely, for the first and the last few rows, suppressing those in between, and also suppresses columns when *x* is too wide.

`printSpMatrix()` basically prints the result of `formatSpMatrix()`.

**Usage**

```
formatSpMatrix(x, digits = NULL, maxp = 1e9,
               cld = getClassDef(class(x)), zero.print = ".",
               col.names, note.dropping.colnames = TRUE, uniDiag = TRUE,
               align = c("fancy", "right"), ...)

printSpMatrix(x, digits = NULL, maxp = max(100L, getOption("max.print")),
              cld = getClassDef(class(x)),
              zero.print = ".", col.names, note.dropping.colnames = TRUE,
              uniDiag = TRUE, col.trailer = "",
              align = c("fancy", "right"), ...)
```

```
printSpMatrix2(x, digits = NULL, maxp = max(100L, getOption("max.print")),
  zero.print = ".", col.names, note.dropping.colnames = TRUE,
  uniDiag = TRUE, suppRows = NULL, suppCols = NULL,
  col.trailer = if(suppCols) "....." else "",
  align = c("fancy", "right"),
  width = getOption("width"), fitWidth = TRUE, ...)
```

## Arguments

|                                     |   |
|-------------------------------------|---|
| <code>x</code>                      | an R object inheriting from class <code>sparseMatrix</code> .   |
| <code>digits</code>                 | significant digits to use for printing, see <code>print.default</code> , the default, <code>NULL</code> , corresponds to using <code>getOption("digits")</code> .   |
| <code>maxp</code>                   | integer, default from <code>options(max.print)</code> , influences how many entries of large matrices are printed at all. Typically should not be smaller than around 1000; values smaller than 100 are silently “rounded up” to 100.   |
| <code>cld</code>                    | the class definition of <code>x</code> ; must be equivalent to <code>getClassDef(class(x))</code> and exists mainly for possible speedup.   |
| <code>zero.print</code>             | character which should be printed for <i>structural</i> zeroes. The default <code>"."</code> may occasionally be replaced by <code>" "</code> (blank); using <code>"0"</code> would look almost like <code>print()</code> ing of non-sparse matrices.   |
| <code>col.names</code>              | logical or string specifying if and how column names of <code>x</code> should be printed, possibly abbreviated. The default is taken from <code>options("sparse.colnames")</code> if that is set, otherwise <code>FALSE</code> unless there are less than ten columns. When <code>TRUE</code> the full column names are printed.<br>When <code>col.names</code> is a string beginning with <code>"abb"</code> or <code>"sub"</code> and ending with an integer <code>n</code> (i.e., of the form <code>"abb... &lt;n&gt;"</code> ), the column names are <code>abbreviate()</code> d or <code>substring()</code> ed to (target) length <code>n</code> , see the examples. |
| <code>note.dropping.colnames</code> | logical specifying, when <code>col.names</code> is <code>FALSE</code> if the dropping of the column names should be noted, <code>TRUE</code> by default.  |
| <code>uniDiag</code>                | logical indicating if the diagonal entries of a sparse unit triangular or unit-diagonal matrix should be formatted as <code>"I"</code> instead of <code>"1"</code> (to emphasize that the 1's are “structural”).  |
| <code>col.trailer</code>            | a string to be appended to the right of each column; this is typically made use of by <code>show(&lt;sparseMatrix&gt;)</code> only, when suppressing columns.   |
| <code>suppRows, suppCols</code>     | logicals or <code>NULL</code> , for <code>printSpMatrix2()</code> specifying if rows or columns should be suppressed in printing. If <code>NULL</code> , sensible defaults are determined from <code>dim(x)</code> and <code>options(c("width", "max.print"))</code> . Setting both to <code>FALSE</code> may be a very bad idea.   |
| <code>align</code>                  | a string specifying how the <code>zero.print</code> codes should be aligned, i.e., padded as strings. The default, <code>"fancy"</code> , takes some effort to align the typical <code>zero.print = "."</code> with the position of 0, i.e., the first decimal (one left of decimal point) of the numbers printed, whereas <code>align = "right"</code> just makes use of <code>print(*, right = TRUE)</code> .   |
| <code>width</code>                  | number, a positive integer, indicating the approximately desired (line) width of the output, see also <code>fitWidth</code> .   |

|          |  |
|----------|--|
| fitWidth | logical indicating if some effort should be made to match the desired width or temporarily enlarge that if deemed necessary. |
| ...      | unused optional arguments.   |

## Details

**formatSpMatrix:** If `x` is large, only the first rows making up the approximately first `maxp` entries is used, otherwise all of `x`. `.formatSparseSimple()` is applied to (a dense version of) the matrix. Then, `formatSparseM` is used, unless in trivial cases or for sparse matrices without `x` slot.

## Value

|                               |  |
|-------------------------------|--|
| <code>formatSpMatrix()</code> | returns a character matrix with possibly empty column names, depending on <code>col.names</code> etc, see above. |
| <code>printSpMatrix*</code>   | return <code>x</code> <i>invisibly</i> , see <code>invisible</code> .  |

## Author(s)

Martin Maechler

## See Also

the virtual class `sparseMatrix` and the classes extending it; maybe `sparseMatrix` or `spMatrix` as simple constructors of such matrices.

The underlying utilities `formatSparseM` and `.formatSparseSimple()` (on the same page).

## Examples

```
f1 <- gl(5, 3, labels = LETTERS[1:5])
X <- as(f1, "sparseMatrix")
X ## <==> show(X) <==> print(X)
t(X) ## shows column names, since only 5 columns

X2 <- as(gl(12, 3, labels = paste(LETTERS[1:12], "c", sep=".")),
        "sparseMatrix")
X2
## less nice, but possible:
print(X2, col.names = TRUE) # use [,1] [,2] .. => does not fit

## Possibilities with column names printing:
t(X2) # suppressing column names
print(t(X2), col.names=TRUE)
print(t(X2), zero.print = "", col.names="abbr. 1")
print(t(X2), zero.print = "-", col.names="substring 2")
```

## Description

Computes the pivoted QR factorization of an  $m \times n$  real matrix  $A$ , which has the general form

$$P_1 A P_2 = Q R$$

or (equivalently)

$$A = P_1' Q R P_2'$$

where  $P_1$  and  $P_2$  are permutation matrices,  $Q = \prod_{j=1}^n H_j$  is an  $m \times m$  orthogonal matrix equal to the product of  $n$  Householder matrices  $H_j$ , and  $R$  is an  $m \times n$  upper trapezoidal matrix.

`denseMatrix` use the default method implemented in **base**, namely `qr.default`. It is built on LINPACK routine `dqrdc` and LAPACK routine `dgeqp3`, which do not pivot rows, so that  $P_1$  is an identity matrix.

Methods for `sparseMatrix` are built on CXSparse routines `cs_sqr` and `cs_qr`, which require  $m \geq n$ .

## Usage

```
qr(x, ...)
## S4 method for signature 'dgCMatrix'
qr(x, order = 3L, ...)
```

## Arguments

|                    |  |
|--------------------|--|
| <code>x</code>     | a <b>finite</b> matrix or <b>Matrix</b> to be factorized, satisfying <code>nrow(x) &gt;= ncol(x)</code> if sparse.   |
| <code>order</code> | an integer in <code>0:3</code> passed to CXSparse routine <code>cs_sqr</code> , indicating a strategy for choosing the column permutation $P_2$ . 0 means no column permutation. 1, 2, and 3 indicate a fill-reducing ordering of $A + A'$ , $\tilde{A}'\tilde{A}$ , and $A'A$ , where $\tilde{A}$ is $A$ with “dense” rows removed. Do not set to 0 unless you know that the column order of $A$ is already sensible. |
| <code>...</code>   | further arguments passed to or from methods.   |

## Details

If  $x$  is sparse and structurally rank deficient, having structural rank  $r < n$ , then  $x$  is augmented with  $(n - r)$  rows of (partly non-structural) zeros, such that the augmented matrix has structural rank  $n$ . This augmented matrix is factorized as described above:

$$P_1 A P_2 = P_1 \begin{bmatrix} A_0 \\ 0 \end{bmatrix} P_2 = Q R$$

where  $A_0$  denotes the original, user-supplied  $(m - (n - r)) \times n$  matrix.

## Value

An object representing the factorization, inheriting from virtual S4 class `QR` or S3 class `qr`. The specific class is `qr` unless  $x$  inherits from virtual class `sparseMatrix`, in which case it is `sparseQR`.

})

```

```
    })
```

---

rankMatrix

*Rank of a Matrix*

---

## Description

Compute ‘the’ matrix rank, a well-defined functional in theory(\*), somewhat ambiguous in practice. We provide several methods, the default corresponding to Matlab’s definition.

(\*) The rank of a  $n \times m$  matrix  $A$ ,  $rk(A)$ , is the maximal number of linearly independent columns (or rows); hence  $rk(A) \leq \min(n, m)$ .

## Usage

```
rankMatrix(x, tol = NULL,
           method = c("tolNorm2", "qr.R", "qrLINPACK", "qr",
                     "useGrad", "maybeGrad"),
           sval = svd(x, 0, 0)$d, warn.t = TRUE, warn.qr = TRUE)

qr2rankMatrix(qr, tol = NULL, isBqr = is.qr(qr), do.warn = TRUE)
```

## Arguments

|        |  |
|--------|--|
| x      | numeric matrix, of dimension $n \times m$ , say.   |
| tol    | nonnegative number specifying a (relative, “scalefree”) tolerance for testing of “practically zero” with specific meaning depending on method; by default, $\max(\dim(x)) * .Machine$double.eps$ is according to Matlab’s default (for its only method which is our <code>method="tolNorm2"</code> ).  |
| method | <p>a character string specifying the computational method for the rank, can be abbreviated:</p> <p><b>"tolNorm2"</b>: the number of singular values <math>\geq \text{tol} * \max(\text{sval})</math>;</p> <p><b>"qrLINPACK"</b>: for a dense matrix, this is the rank of <code>qr(x, tol, LAPACK=FALSE)</code> (which is <code>qr(...)\$rank</code>);<br/> This ("qr*", dense) version used to be <i>the</i> recommended way to compute a matrix rank for a while in the past.<br/> For sparse <code>x</code>, this is equivalent to <code>"qr.R"</code>.</p> <p><b>"qr.R"</b>: this is the rank of triangular matrix <math>R</math>, where <code>qr()</code> uses LAPACK or a "sparseQR" method (see <a href="#">qr-methods</a>) to compute the decomposition <math>QR</math>. The rank of <math>R</math> is then defined as the number of “non-zero” diagonal entries <math>d_i</math> of <math>R</math>, and “non-zero”s fulfill <math> d_i  \geq \text{tol} \cdot \max( d_i )</math>.</p> <p><b>"qr"</b>: is for back compatibility; for dense <code>x</code>, it corresponds to <code>"qrLINPACK"</code>, whereas for sparse <code>x</code>, it uses <code>"qr.R"</code>.<br/> For all the "qr*" methods, singular values <code>sval</code> are not used, which may be crucially important for a large sparse matrix <code>x</code>, as in that case, when <code>sval</code> is not specified, the default, computing <code>svd()</code> currently coerces <code>x</code> to a dense matrix.</p> <p><b>"useGrad"</b>: considering the “gradient” of the (decreasing) singular values, the index of the <i>smallest</i> gap.</p> |

|         |   |
|---------|---|
|         | "maybeGrad": choosing method "useGrad" only when that seems <i>reasonable</i> ; otherwise using "tolNorm2".   |
| sval    | numeric vector of non-increasing singular values of <code>x</code> ; typically unspecified and computed from <code>x</code> when needed, i.e., unless <code>method = "qr"</code> .  |
| warn.t  | logical indicating if <code>rankMatrix()</code> should warn when it needs <code>t(x)</code> instead of <code>x</code> . Currently, for <code>method = "qr"</code> only, gives a warning by default because the caller often could have passed <code>t(x)</code> directly, more efficiently. |
| warn.qr | in the <i>QR</i> cases (i.e., if <code>method</code> starts with "qr"), <code>rankMatrix()</code> calls <code>qr2rankMatrix(..., do.warn = warn.qr)</code> , see below.   |
| qr      | an R object resulting from <code>qr(x, ...)</code> , i.e., typically inheriting from class "qr" or "sparseQR".  |
| isBqr   | logical indicating if <code>qr</code> is resulting from <code>base::qr()</code> . (Otherwise, it is typically from <b>Matrix</b> package <code>sparse::qr()</code> .)   |
| do.warn | logical; if true, warn about non-finite diagonal entries in the <i>R</i> matrix of the <i>QR</i> decomposition. Do not change lightly!  |

## Details

`qr2rankMatrix()` is typically called from `rankMatrix()` for the "qr"\* methods, but can be used directly - much more efficiently in case the qr-decomposition is available anyway.

## Value

If `x` is a matrix of all 0 (or of zero dimension), the rank is zero; otherwise, typically a positive integer in `1:min(dim(x))` with attributes detailing the method used.

There are rare cases where the sparse *QR* decomposition “fails” in so far as the diagonal entries of *R*, the  $d_i$  (see above), end with non-finite, typically NaN entries. Then, a warning is signalled (unless `warn.qr / do.warn` is not true) and NA (specifically, `NA_integer_`) is returned.

## Note

For large sparse matrices `x`, unless you can specify `sval` yourself, currently `method = "qr"` may be the only feasible one, as the others need `sval` and call `svd()` which currently coerces `x` to a `denseMatrix` which may be very slow or impossible, depending on the matrix dimensions.

Note that in the case of sparse `x`, `method = "qr"`, all non-strictly zero diagonal entries  $d_i$  where counted, up to including **Matrix** version 1.1-0, i.e., that method implicitly used `tol = 0`, see also the `set.seed(42)` example below.

## zero matrix has rank 0 :
stopifnot(sapply(meths, function(.m.)
                 rankMatrix(matrix(0, 2, 2), method = .m.)) == 0)
```

## Description

Estimate the reciprocal of the condition number of a matrix.

This is a generic function with several methods, as seen by `showMethods(rcond)`.

## Usage

```
rcond(x, norm, ...)

## S4 method for signature 'sparseMatrix,character'
rcond(x, norm, useInv=FALSE, ...)
```

## Arguments

|                     |  |
|---------------------|--|
| <code>x</code>      | an R object that inherits from the <code>Matrix</code> class.  |
| <code>norm</code>   | character string indicating the type of norm to be used in the estimate. The default is "O" for the 1-norm ("O" is equivalent to "1"). For sparse matrices, when <code>useInv=TRUE</code> , <code>norm</code> can be any of the kinds allowed for <code>norm</code> ; otherwise, the other possible value is "I" for the infinity norm, see also <code>norm</code> .   |
| <code>useInv</code> | logical (or "Matrix" containing <code>solve(x)</code> ). If not false, compute the reciprocal condition number as $1/(\ x\  \cdot \ x^{-1}\ )$ , where $x^{-1}$ is the inverse of $x$ , <code>solve(x)</code> .<br>This may be an efficient alternative (only) in situations where <code>solve(x)</code> is fast (or known), e.g., for (very) sparse or triangular matrices.<br>Note that the <i>result</i> may differ depending on <code>useInv</code> , as per default, when it is false, an <i>approximation</i> is computed. |
| <code>...</code>    | further arguments passed to or from other methods.   |

## Value

An estimate of the reciprocal condition number of `x`.

## BACKGROUND

The condition number of a regular (square) matrix is the product of the `norm` of the matrix and the norm of its inverse (or pseudo-inverse).

More generally, the condition number is defined (also for non-square matrices  $A$ ) as

$$\kappa(A) = \frac{\max_{\|v\|=1} \|Av\|}{\min_{\|v\|=1} \|Av\|}.$$

Whenever `x` is *not* a square matrix, in our method definitions, this is typically computed via `rcond(qr.R(qr(X)), ...)` where  $X$  is `x` or `t(x)`.

The condition number takes on values between 1 and infinity, inclusive, and can be viewed as a factor by which errors in solving linear systems with this matrix as coefficient matrix could be magnified.

`rcond()` computes the *reciprocal* condition number  $1/\kappa$  with values in  $[0, 1]$  and can be viewed as a scaled measure of how close a matrix is to being rank deficient (aka "singular").

Condition numbers are usually estimated, since exact computation is costly in terms of floating-point operations. An (over) estimate of reciprocal condition number is given, since by doing so overflow is avoided. Matrices are well-conditioned if the reciprocal condition number is near 1 and ill-conditioned if it is near zero.

## References

Golub, G., and Van Loan, C. F. (1989). *Matrix Computations*, 2nd edition, Johns Hopkins, Baltimore.

## See Also

`norm`, `kappa()` from package **base** computes an *approximate* condition number of a “traditional” matrix, even non-square ones, with respect to the  $p = 2$  (Euclidean) `norm.solve`.

`condest`, a newer *approximate* estimate of the (1-norm) condition number, particularly efficient for large sparse matrices.

## Examples

```
x <- Matrix(rnorm(9), 3, 3)
rcond(x)
## typically "the same" (with more computational effort):
1 / (norm(x) * norm(solve(x)))
rcond(Hilbert(9)) # should be about 9.1e-13

## For non-square matrices:
rcond(x1 <- cbind(1,1:10))# 0.05278
rcond(x2 <- cbind(x1, 2:11))# practically 0, since x2 does not have full rank

## sparse
(S1 <- Matrix(rbind(0:1,0, diag(3:-2))))
rcond(S1)
m1 <- as(S1, "denseMatrix")
all.equal(rcond(S1), rcond(m1))

## wide and sparse
rcond(Matrix(cbind(0, diag(2:-1))))

## Large sparse example -----
m <- Matrix(c(3,0:2), 2,2)
M <- bdiag(kronecker(Diagonal(2), m), kronecker(m,m))
36*(iM <- solve(M)) # still sparse
MM <- kronecker(Diagonal(10), kronecker(Diagonal(5),kronecker(m,M)))
dim(M3 <- kronecker(bdiag(M,M),MM)) # 12'800 ^ 2
if(interactive()) ## takes about 2 seconds if you have >= 8 GB RAM
  system.time(r <- rcond(M3))
## whereas this is *fast* even though it computes solve(M3)
system.time(r. <- rcond(M3, useInv=TRUE))
if(interactive()) ## the values are not the same
  c(r, r.) # 0.05555 0.013888
## for all 4 norms available for sparseMatrix :
cbind(rr <- sapply(c("1","I","F","M"),
  function(N) rcond(M3, norm=N, useInv=TRUE)))
```

**Description**

`rep2abI(x, times)` conceptually computes `rep.int(x, times)` but with an `abIndex` class result.

**Usage**

```
rep2abI(x, times)
```

**Arguments**

`x`                      numeric vector  
`times`                  integer (valued) scalar: the number of repetitions

**Value**

a vector of `class abIndex`

**See Also**

`rep.int()`, the base function; `abIseq`, `abIndex`.

**Examples**

```
(ab <- rep2abI(2:7, 4))
stopifnot(identical(as(ab, "numeric"),
  rep(2:7, 4)))
```

---

rleDiff-class

---

*Class "rleDiff" of rle(diff(.)) Stored Vectors*

---

**Description**

Class "rleDiff" is for compactly storing long vectors which mainly consist of *linear* stretches. For such a vector `x`, `diff(x)` consists of *constant* stretches and is hence well compressable via `rle()`.

**Objects from the Class**

Objects can be created by calls of the form `new("rleDiff", ...)`.

Currently experimental, see below.

**Slots**

**first:** A single number (of class "numLike", a class union of "numeric" and "logical").

**rle:** Object of class "rle", basically a `list` with components "lengths" and "values", see `rle()`. As this is used to encode potentially huge index vectors, `lengths` may be of type `double` here.

**Methods**

There is a simple `show` method only.

**Note**

This is currently an *experimental* auxiliary class for the class [abIndex](#), see there.

**See Also**

[rle](#), [abIndex](#).

**Examples**

```
showClass("rleDiff")

ab <- c(abIseq(2, 100), abIseq(20, -2))
ab@rleD # is "rleDiff"
```

---

|               |                             |
|---------------|-----------------------------|
| rsparsematrix | <i>Random Sparse Matrix</i> |
|---------------|-----------------------------|

---

**Description**

Generate a random sparse matrix efficiently. The default has rounded gaussian non-zero entries, and `rand.x = NULL` generates random pattern matrices, i.e. inheriting from [nsparseMatrix](#).

**Usage**

```
rsparsematrix(nrow, ncol, density, nnz = round(density * maxE),
              symmetric = FALSE,
              rand.x = function(n) signif(rnorm(n), 2), ...)
```

**Arguments**

|                         |   |
|-------------------------|---|
| <code>nrow, ncol</code> | number of rows and columns, i.e., the matrix dimension ( <a href="#">dim</a> ).   |
| <code>density</code>    | optional number in $[0, 1]$ , the density is the proportion of non-zero entries among all matrix entries. If specified it determines the default for <code>nnz</code> , otherwise <code>nnz</code> needs to be specified.   |
| <code>nnz</code>        | number of non-zero entries, for a sparse matrix typically considerably smaller than <code>nrow*ncol</code> . Must be specified if <code>density</code> is not.  |
| <code>symmetric</code>  | logical indicating if result should be a matrix of class <a href="#">symmetricMatrix</a> . Note that in the symmetric case, <code>nnz</code> denotes the number of non zero entries of the upper (or lower) part of the matrix, including the diagonal.   |
| <code>rand.x</code>     | <a href="#">NULL</a> or the random number generator for the <code>x</code> slot, a <a href="#">function</a> such that <code>rand.x(n)</code> generates a numeric vector of length <code>n</code> . Typical examples are <code>rand.x = rnorm</code> , or <code>rand.x = runif</code> ; the default is nice for didactical purposes. |
| <code>...</code>        | optionally further arguments passed to <a href="#">sparseMatrix()</a> , notably <code>repr</code> .   |

**Details**

The algorithm first samples “encoded”  $(i, j)$ s without replacement, via one dimensional indices, if not `symmetric` [sample.int](#)(`nrow*ncol`, `nnz`), then—if `rand.x` is not `NULL`—gets `x <- rand.x(nnz)` and calls [sparseMatrix](#)(`i=i`, `j=j`, `x=x`, `...`). When `rand.x=NULL`, [sparseMatrix](#)(`i=i`, `j=j`, `...`) will return a pattern matrix (i.e., inheriting from [nsparseMatrix](#)).

**Value**

a `sparseMatrix`, say `M` of dimension `(nrow, ncol)`, i.e., with `dim(M) == c(nrow, ncol)`, if symmetric is not true, with `nzM <- nnzero(M)` fulfilling `nzM <= nnz` and typically, `nzM == nnz`.

**Author(s)**

Martin Maechler

**Examples**

```
set.seed(17) # to be reproducible
M <- rsparsematrix(8, 12, nnz = 30) # small example, not very sparse
M
M1 <- rsparsematrix(1000, 20, nnz = 123, rand.x = runif)
summary(M1)

## a random *symmetric* Matrix
(S9 <- rsparsematrix(9, 9, nnz = 10, symmetric=TRUE)) # dsCMatrix
nnzero(S9) # ~ 20: as 'nnz' only counts one "triangle"

## a random patter*n* aka boolean Matrix (no 'x' slot):
(n7 <- rsparsematrix(5, 12, nnz = 10, rand.x = NULL))

## a [T]riplet representation sparseMatrix:
T2 <- rsparsematrix(40, 12, nnz = 99, repr = "T")
head(T2)
```

---

RsparseMatrix-class

*Class "RsparseMatrix" of Sparse Matrices in Row-compressed Form*

---

**Description**

The "RsparseMatrix" class is the virtual class of all sparse matrices coded in sorted compressed row-oriented form. Since it is a virtual class, no objects may be created from it. See `showClass("RsparseMatrix")` for its subclasses.

**Slots**

**j:** Object of class "integer" of length `nnzero` (number of non-zero elements). These are the row numbers for each non-zero element in the matrix.

**p:** Object of class "integer" of pointers, one for each row, to the initial (zero-based) index of elements in the row.

**Dim, Dimnames:** inherited from the superclass, see `sparseMatrix`.

**Extends**

Class "sparseMatrix", directly. Class "Matrix", by class "sparseMatrix".

## Methods

Originally, **few** methods were defined on purpose, as we rather use the `CsparseMatrix` in `Matrix`. Then, more methods were added but *beware* that these typically do *not* return "RsparseMatrix" results, but rather `Csparse*` or `Tsparse*` ones; e.g., `R[i, j] <- v` for an "RsparseMatrix" R works, but after the assignment, R is a (triplet) "TsparseMatrix".

```
t signature(x = "RsparseMatrix"):...
```

```
coerce signature(from = "RsparseMatrix", to = "CsparseMatrix"):...
```

```
coerce signature(from = "RsparseMatrix", to = "TsparseMatrix"):...
```

## See Also

its superclass, `sparseMatrix`, and, e.g., class `dgRMatrix` for the links to other classes.

## Examples

```
showClass("RsparseMatrix")
```

---

Schur-class

*Schur Factorizations*

---

## Description

Schur is the class of Schur factorizations of  $n \times n$  real matrices  $A$ , having the general form

$$A = QTQ'$$

where  $Q$  is an orthogonal matrix and  $T$  is a block upper triangular matrix with  $1 \times 1$  or  $2 \times 2$  diagonal blocks specifying the real and complex conjugate eigenvalues of  $A$ . The column vectors of  $Q$  are the Schur vectors of  $A$ , and  $T$  is the Schur form of  $A$ .

The Schur factorization generalizes the spectral decomposition of normal matrices  $A$ , whose Schur form is block diagonal, to arbitrary square matrices.

## Details

The matrix  $A$  and its Schur form  $T$  are *similar* and thus have the same spectrum. The eigenvalues are computed trivially as the eigenvalues of the diagonal blocks of  $T$ .

## Slots

`Dim`, `Dimnames` inherited from virtual class `MatrixFactorization`.

`Q` an orthogonal matrix, inheriting from virtual class `Matrix`.

`T` a block upper triangular matrix, inheriting from virtual class `Matrix`. The diagonal blocks have dimensions 1-by-1 or 2-by-2.

`EValues` a numeric or complex vector containing the eigenvalues of the diagonal blocks of `T`, which are the eigenvalues of `T` and consequently of the factorized matrix.

## Extends

Class `SchurFactorization`, directly. Class `MatrixFactorization`, by class `SchurFactorization`, distance 2.

## Instantiation

Objects can be generated directly by calls of the form `new("Schur", ...)`, but they are more typically obtained as the value of `Schur(x)` for `x` inheriting from `Matrix` (often `dgeMatrix`).

## Methods

```
determinant signature(from = "Schur", logarithm = "logical"): computes
the determinant of the factorized matrix A or its logarithm.
expand1 signature(x = "Schur"): see expand1-methods.
expand2 signature(x = "Schur"): see expand2-methods.
solve signature(a = "Schur", b = .): see solve-methods.
```

Class [dgeMatrix](#).  
Generic functions [Schur](#), [expand1](#) and [expand2](#).

## Examples

```
showClass("Schur")
set.seed(0)

n <- 4L
(A <- Matrix(rnorm(n * n), n, n))

## With dimnames, to see that they are propagated :
dimnames(A) <- list(paste0("r", seq_len(n)),
                    paste0("c", seq_len(n)))

(sch.A <- Schur(A))
str(e.sch.A <- expand2(sch.A), max.level = 2L)

## A ~ Q T Q' in floating point
stopifnot(exprs = {
  identical(names(e.sch.A), c("Q", "T", "Q."))
  all.equal(A, with(e.sch.A, Q %*% T %*% Q.))
})

## Factorization handled as factorized matrix
b <- rnorm(n)
stopifnot(all.equal(det(A), det(sch.A)),
          all.equal(solve(A, b), solve(sch.A, b)))

## One of the non-general cases:
Schur(Diagonal(6L))
```

## Description

Computes the Schur factorization of an  $n \times n$  real matrix  $A$ , which has the general form

$$A = QTQ'$$

where  $Q$  is an orthogonal matrix and  $T$  is a block upper triangular matrix with  $1 \times 1$  and  $2 \times 2$  diagonal blocks specifying the real and complex conjugate eigenvalues of  $A$ . The column vectors of  $Q$  are the Schur vectors of  $A$ , and  $T$  is the Schur form of  $A$ .

Methods are built on LAPACK routine `dgees`.

## Usage

```
Schur(x, vectors = TRUE, ...)
```

## Arguments

|                      |   |
|----------------------|---|
| <code>x</code>       | a <a href="#">finite</a> square matrix or <code>Matrix</code> to be factorized.                               |
| <code>vectors</code> | a logical. If <code>TRUE</code> (the default), then Schur vectors are computed in addition to the Schur form. |
| <code>...</code>     | further arguments passed to or from methods.  |

## Value

An object representing the factorization, inheriting from virtual class `SchurFactorization` if `vectors = TRUE`. Currently, the specific class is always `Schur` in that case. An exception is if `x` is a traditional matrix, in which case the result is a named list containing `Q`, `T`, and `EValues` slots of the `Schur` object.

If `vectors = FALSE`, then the result is the same named list but without `Q`.

## S4 method for signature 'CHMfactor,dgCMatrix'
solve(a, b, system = c("A", "LDLt", "LD", "DLt", "L", "Lt", "D", "P", "Pt"), ...)

```

## Arguments

|                     |   |
|---------------------|---|
| <code>a</code>      | a <a href="#">finite</a> square matrix or <a href="#">Matrix</a> containing the coefficients of the linear system, or otherwise a <a href="#">MatrixFactorization</a> , in which case methods behave (by default) as if the factorized matrix were specified.   |
| <code>b</code>      | a vector, <a href="#">sparseVector</a> , matrix, or <a href="#">Matrix</a> satisfying <code>NROW(b) == nrow(a)</code> , giving the right-hand side(s) of the linear system. Vectors <code>b</code> are treated as <code>length(b)-by-1</code> matrices. If <code>b</code> is missing, then methods take <code>b</code> to be an identity matrix.  |
| <code>tol</code>    | a non-negative number. For <code>a</code> inheriting from <a href="#">denseMatrix</a> , an error is signaled if the reciprocal one-norm condition number (see <a href="#">rcond</a> ) of <code>a</code> is less than <code>tol</code> , indicating that <code>a</code> is near-singular. For <code>a</code> of class <a href="#">sparseLU</a> , an error is signaled if the ratio <code>min(d)/max(d)</code> is less than <code>tol</code> , where <code>d = abs(diag(a@U))</code> . (Interpret with care, as this ratio is a cheap heuristic and <i>not</i> in general equal to or even proportional to the reciprocal one-norm condition number.) Setting <code>tol = 0</code> disables the test. |
| <code>sparse</code> | a logical indicating if the result should be formally sparse, i.e., if the result should inherit from virtual class <a href="#">sparseMatrix</a> . Only methods for sparse <code>a</code> and missing or matrix <code>b</code> have this argument. Methods for missing or sparse <code>b</code> use <code>sparse = TRUE</code> by default. Methods for dense <code>b</code> use <code>sparse = FALSE</code> by default.   |
| <code>system</code> | a string specifying a linear system to be solved. Only methods for <code>a</code> inheriting from <a href="#">CHMfactor</a> have this argument. See ‘Details’.  |
| <code>...</code>    | further arguments passed to or from methods.  |

## Details

Methods for general and symmetric matrices `a` compute a triangular factorization (LU, Bunch-Kaufman, or Cholesky) and call the method for the corresponding factorization class. The factorization is sparse if `a` is. Methods for sparse, symmetric matrices `a` attempt a Cholesky factorization and perform an LU factorization only if that fails (typically because `a` is not positive definite).

Triangular, diagonal, and permutation matrices do not require factorization (they are already “factors”), hence methods for those are implemented directly. For triangular `a`, solutions are obtained by forward or backward substitution; for diagonal `a`, they are obtained by scaling the rows of `b`; and for permutations `a`, they are obtained by permuting the rows of `b`.

Methods for dense `a` are built on 14 LAPACK routines: class `d..Matrix`, where `.. = (ge|tr|tp|sy|sp|po|pp)`, uses routines `d..tri` and `d..trs` for missing and non-missing `b`, respectively. A corollary is that these methods always give a dense result.

Methods for sparse  $a$  are built on CXSparse routines `cs_lsolve`, `cs_usolve`, and `cs_spsolve` and CHOLMOD routines `cholmod_solve` and `cholmod_spsolve`. By default, these methods give a vector result if  $b$  is a vector, a sparse matrix result if  $b$  is missing or a sparse matrix, and a dense matrix result if  $b$  is a dense matrix. One can override this behaviour by setting the `sparse` argument, where available, but that should be done with care. Note that a sparse result may be sparse only in the formal sense and not at all in the mathematical sense, depending on the nonzero patterns of  $a$  and  $b$ . Furthermore, whereas dense results are fully preallocated, sparse results must be “grown” in a loop over the columns of  $b$ .

Methods for  $a$  of class `sparseQR` are simple wrappers around `qr.coef`, giving the *least squares* solution in overdetermined cases.

Methods for  $a$  inheriting from `CHMfactor` can solve systems other than the default one  $AX = B$ . The correspondence between its `system` argument the system actually solved is outlined in the table below. See `CHMfactor-class` for a definition of notation.

| system | <code>isLDL(a)=TRUE</code> | <code>isLDL(a)=FALSE</code> |

           all.equal(as(.I0,"diagonalMatrix"), Diagonal(n)) )

```

---

sparse.model.matrix

*Construct Sparse Design / Model Matrices*

---

## Description

Construct a sparse model or “design” matrix, from a formula and data frame (sparse.model.matrix) or a single factor (fac2sparse).

The fac2[Ss]parse() functions are utilities, also used internally in the principal user level function sparse.model.matrix().

## Usage

```

sparse.model.matrix(object, data = environment(object),
  contrasts.arg = NULL, xlev = NULL, transpose = FALSE,
  drop.unused.levels = FALSE, row.names = TRUE,
  sep = "", verbose = FALSE, ...)

fac2sparse(from, to = c("d", "l", "n"),
  drop.unused.levels = TRUE, repr = c("C", "R", "T"), giveCsparse)
fac2Sparse(from, to = c("d", "l", "n"),
  drop.unused.levels = TRUE, repr = c("C", "R", "T"), giveCsparse,
  factorPatt12, contrasts.arg = NULL)

```

## Arguments

|               |   |
|---------------|---|
| object        | an object of an appropriate class. For the default method, a model formula or terms object.   |
| data          | a data frame created with <code>model.frame</code> . If another sort of object, <code>model.frame</code> is called first.   |
| contrasts.arg | <p><b>for</b> <code>sparse.model.matrix()</code>: A list, whose entries are contrasts suitable for input to the <code>contrasts</code> replacement function and whose names are the names of columns of data containing <code>factors</code>.</p> <p><b>for</b> <code>fac2Sparse()</code>: character string or NULL or (coercable to) <code>"sparseMatrix"</code>, specifying the contrasts to be applied to the factor levels.</p> |
| xlev          | to be used as argument of <code>model.frame</code> if data has no "terms" attribute.  |

|                                 |   |
|---------------------------------|---|
| <code>transpose</code>          | logical indicating if the <i>transpose</i> should be returned; if the transposed is used anyway, setting <code>transpose = TRUE</code> is more efficient.   |
| <code>drop.unused.levels</code> | should factors have unused levels dropped? The default for <code>sparse.model.matrix</code> has been changed to <code>FALSE</code> , 2010-07, for compatibility with R's standard (dense) <code>model.matrix()</code> .                                   |
| <code>row.names</code>          | logical indicating if row names should be used.   |
| <code>sep</code>                | <code>character</code> string passed to <code>paste()</code> when constructing column names from the variable name and its levels.  |
| <code>verbose</code>            | logical or integer indicating if (and how much) progress output should be printed.  |
| <code>...</code>                | further arguments passed to or from other methods.  |
| <code>from</code>               | (for <code>fac2sparse()</code> ) a <code>factor</code> .  |
| <code>to</code>                 | a character indicating the "kind" of sparse matrix to be returned. The default, "d" is for <code>double</code> .  |
| <code>giveCsparse</code>        | <b>deprecated</b> , replaced with <code>repr</code> ; logical indicating if the result must be a <code>CsparseMatrix</code> .   |
| <code>repr</code>               | <code>character</code> string, one of "C", "T", or "R", specifying the sparse <i>representation</i> to be used for the result, i.e., one from the super classes <code>CsparseMatrix</code> , <code>TsparseMatrix</code> , or <code>RsparseMatrix</code> . |
| <code>factorPatt12</code>       | logical vector, say <code>fp</code> , of length two; when <code>fp[1]</code> is true, return "contrasted" $t(X)$ ; when <code>fp[2]</code> is true, the original ("dummy") $t(X)$ , i.e, the result of <code>fac2sparse()</code> .                        |

### Value

a sparse matrix, extending `CsparseMatrix` (for `fac2sparse()` if `repr = "C"` as per default; a `TsparseMatrix` or `RsparseMatrix`, otherwise).

For `fac2Sparse()`, a `list` of length two, both components with the corresponding transposed model matrix, where the corresponding `factorPatt12` is true.

`fac2sparse()`, the basic workhorse of `sparse.model.matrix()`, returns the *transpose* (`t`) of the model matrix.

### Note

`model.Matrix(sparse = TRUE)` from package **MatrixModels** may be nowadays be preferable to `sparse.model.matrix`, as `model.Matrix` returns an object of class `modelMatrix` with additional slots `assign` and `contrasts` relating to the model variables.

### Author(s)

Doug Bates and Martin Maechler, with initial suggestions from Tim Hesterberg.

### See Also

`model.matrix` in package **stats**, part of base R.

`model.Matrix` in package **MatrixModels**; see 'Note'.

`as(f, "sparseMatrix")` (see `coerce(from = "factor", ...)` in the class doc `sparse-Matrix`) produces the *transposed* sparse model matrix for a single factor `f` (and *no* contrasts).

## Examples

```
dd <- data.frame(a = gl(3,4), b = gl(4,1,12))# balanced 2-way
options("contrasts") # the default: "contr.treatment"
sparse.model.matrix(~ a + b, dd)
sparse.model.matrix(~ -1+ a + b, dd)# no intercept --> even sparser
sparse.model.matrix(~ a + b, dd, contrasts = list(a="contr.sum"))
sparse.model.matrix(~ a + b, dd, contrasts = list(b="contr.SAS"))

## Sparse method is equivalent to the traditional one :
stopifnot(all(sparse.model.matrix(~ a + b, dd) ==
  Matrix(model.matrix(~ a + b, dd), sparse=TRUE)),
  all(sparse.model.matrix(~0 + a + b, dd) ==
  Matrix(model.matrix(~0 + a + b, dd), sparse=TRUE)))

(ff <- gl(3,4,, c("X","Y", "Z")))
fac2sparse(ff) # 3 x 12 sparse Matrix of class "dgCMatrix"
##
## X  1 1 1 1 . . . . .
## Y  . . . . 1 1 1 1 . . .
## Z  . . . . . 1 1 1 1
##

## can also be computed via sparse.model.matrix():
f30 <- gl(3,0 )
f12 <- gl(3,0, 12)
stopifnot(
  all.equal(t( fac2sparse(ff) ),
    sparse.model.matrix(~ 0+ff),
    tolerance = 0, check.attributes=FALSE),
  is(M <- fac2sparse(f30, drop= TRUE), "CsparseMatrix"), dim(M) == c(0, 0),
  is(M <- fac2sparse(f30, drop=FALSE), "CsparseMatrix"), dim(M) == c(3, 0),
  is(M <- fac2sparse(f12, drop= TRUE), "CsparseMatrix"), dim(M) == c(0,12),
  is(M <- fac2sparse(f12, drop=FALSE), "CsparseMatrix"), dim(M) == c(3,12)
)
```

sparseLU-class

*Sparse LU Factorizations*

---

## Description

sparseLU is the class of sparse, row- and column-pivoted LU factorizations of  $n \times n$  real matrices  $A$ , having the general form

$$P_1 A P_2 = LU$$

or (equivalently)

$$A = P_1' L U P_2'$$

where  $P_1$  and  $P_2$  are permutation matrices,  $L$  is a unit lower triangular matrix, and  $U$  is an upper triangular matrix.

## Slots

Dim, Dimnames inherited from virtual class [MatrixFactorization](#).

L an object of class [dtCMatrix](#), the unit lower triangular  $L$  factor.

U an object of class [dtCMatrix](#), the upper triangular  $U$  factor.

$p, q$  0-based integer vectors of length `Dim[1]`, specifying the permutations applied to the rows and columns of the factorized matrix.  $q$  of length 0 is valid and equivalent to the identity permutation, implying no column pivoting. Using R syntax, the matrix  $P_1 A P_2$  is precisely `A[p+1, q+1]` (`A[p+1, ]` when  $q$  has length 0).

### Extends

Class `LU`, directly. Class `MatrixFactorization`, by class `LU`, distance 2.

### Instantiation

Objects can be generated directly by calls of the form `new("sparseLU", ...)`, but they are more typically obtained as the value of `lu(x)` for  $x$  inheriting from `sparseMatrix` (often `dgCMatrix`).

### Methods

```
determinant signature(from = "sparseLU", logarithm = "logical"): computes the determinant of the factorized matrix A or its logarithm.
expand signature(x = "sparseLU"): see expand-methods.
expand1 signature(x = "sparseLU"): see expand1-methods.
expand2 signature(x = "sparseLU"): see expand2-methods.
solve signature(a = "sparseLU", b = .): see solve-methods.
```

sparseMatrix

*General Sparse Matrix Construction from Nonzero Entries*

## Description

User-friendly construction of sparse matrices (inheriting from virtual [class CsparseMatrix](#), [RsparseMatrix](#), or [TsparseMatrix](#)) from the positions and values of their nonzero entries.

This interface is recommended over direct construction via calls such as [new](#)("...[CRT]Matrix", ...).

## Usage

```

sparseMatrix(i, j, p, x, dims, dimnames,
  symmetric = FALSE, triangular = FALSE, index1 = TRUE,
  repr = c("C", "R", "T"), giveCsparse,
  check = TRUE, use.last.ij = FALSE)

```

## Arguments

- |      |  |
|------|--|
| i, j | integer vectors of equal length specifying the positions (row and column indices) of the nonzero (or non-TRUE) entries of the matrix. Note that, when <i>x</i> is non-missing, the $x_k$ corresponding to <i>repeated</i> pairs $(i_k, j_k)$ are <i>added</i> , for consistency with the definition of class <a href="#">TsparseMatrix</a> , unless <code>use.last.ij</code> is TRUE, in which case only the <i>last</i> such $x_k$ is used. |
| p    | integer vector of pointers, one for each column (or row), to the initial (zero-based) index of elements in the column (or row). Exactly one of <i>i</i> , <i>j</i> , and <i>p</i> must be missing.   |

|                          |  |
|--------------------------|--|
| <code>x</code>           | optional, typically nonzero values for the matrix entries. If specified, then the length must equal that of <code>i</code> (or <code>j</code> ) or equal 1, in which case <code>x</code> is recycled as necessary. If missing, then the result is a nonzero pattern matrix, i.e., inheriting from class <code>nsparseMatrix</code> . |
| <code>dims</code>        | optional length-2 integer vector of matrix dimensions. If missing, then <code>!index1+c(max(i),max(j))</code> is used.   |
| <code>dimnames</code>    | optional list of <code>dimnames</code> ; if missing, then <code>NULL</code> ones are used.   |
| <code>symmetric</code>   | logical indicating if the resulting matrix should be symmetric. In that case, $(i, j, p)$ should specify only one triangle (upper or lower).   |
| <code>triangular</code>  | logical indicating if the resulting matrix should be triangular. In that case, $(i, j, p)$ should specify only one triangle (upper or lower).  |
| <code>index1</code>      | logical. If <code>TRUE</code> (the default), then <code>i</code> and <code>j</code> are interpreted as 1-based indices, following the R convention. That is, counting of rows and columns starts at 1. If <code>FALSE</code> , then they are interpreted as 0-based indices.   |
| <code>repr</code>        | character string, one of "C", "R", and "T", specifying the representation of the sparse matrix result, i.e., specifying one of the virtual classes <code>CsparseMatrix</code> , <code>RsparseMatrix</code> , and <code>TsparseMatrix</code> .  |
| <code>giveCsparse</code> | ( <b>deprecated</b> , replaced by <code>repr</code> ) logical indicating if the result should inherit from <code>CsparseMatrix</code> or <code>TsparseMatrix</code> . Note that operations involving <code>CsparseMatrix</code> are very often (but not always) more efficient.  |
| <code>check</code>       | logical indicating whether to check that the result is formally valid before returning. Do not set to <code>FALSE</code> unless you know what you are doing!   |
| <code>use.last.ij</code> | logical indicating if, in the case of repeated (duplicated) pairs $(i_k, j_k)$ , only the last pair should be used. <code>FALSE</code> (the default) is consistent with the definition of class <code>TsparseMatrix</code> .   |

## Details

Exactly one of the arguments `i`, `j` and `p` must be missing.

In typical usage, `p` is missing, `i` and `j` are vectors of positive integers and `x` is a numeric vector. These three vectors, which must have the same length, form the triplet representation of the sparse matrix.

If `i` or `j` is missing then `p` must be a non-decreasing integer vector whose first element is zero. It provides the compressed, or “pointer” representation of the row or column indices, whichever is missing. The expanded form of `p`, `rep(seq_along(dp), dp)` where `dp <- diff(p)`, is used as the (1-based) row or column indices.

You cannot set both `singular` and `triangular` to true; rather use `Diagonal()` (or its alternatives, see there).

The values of `i`, `j`, `p` and `index1` are used to create 1-based index vectors `i` and `j` from which a `TsparseMatrix` is constructed, with numerical values given by `x`, if non-missing. Note that in that case, when some pairs  $(i_k, j_k)$  are repeated (aka “duplicated”), the corresponding  $x_k$  are *added*, in consistency with the definition of the `TsparseMatrix` class, unless `use.last.ij` is set to true.

By default, when `repr = "C"`, the `CsparseMatrix` derived from this triplet form is returned, where `repr = "R"` now allows to directly get an `RsparseMatrix` and `repr = "T"` leaves the result as `TsparseMatrix`.

The reason for returning a `CsparseMatrix` object instead of the triplet format by default is that the compressed column form is easier to work with when performing matrix operations. In particular, if there are no zeros in `x` then a `CsparseMatrix` is a unique representation of the sparse matrix.

**Value**

A sparse matrix, by default in compressed sparse column format and (formally) without symmetric or triangular structure, i.e., by default inheriting from both [CsparseMatrix](#) and [generalMatrix](#).

**Note**

You *do* need to use `index1 = FALSE` (or add + 1 to `i` and `j`) if you want use the 0-based `i` (and `j`) slots from existing sparse matrices.

**See Also**

[Matrix](#)(\*, sparse=TRUE) for the constructor of such matrices from a *dense* matrix. That is easier in small sample, but much less efficient (or impossible) for large matrices, where something like `sparseMatrix()` is needed. Further [bdiag](#) and [Diagonal](#) for (block-)diagonal and [bandSparse](#) for banded sparse matrix constructors.

Random sparse matrices via [rsparsematrix\(\)](#).

The standard R [xtabs](#)(\*, sparse=TRUE), for sparse tables and [sparse.model.matrix\(\)](#) for building sparse model matrices.

Consider [CsparseMatrix](#) and similar class definition help files.

**Examples**

```
## simple example
i <- c(1,3:8); j <- c(2,9,6:10); x <- 7 * (1:7)
(A <- sparseMatrix(i, j, x = x)) ## 8 x 10 "dgCMatrix"
summary(A)
str(A) # note that *internally* 0-based row indices are used

(sA <- sparseMatrix(i, j, x = x, symmetric = TRUE)) ## 10 x 10 "dsCMatrix"
(tA <- sparseMatrix(i, j, x = x, triangular= TRUE)) ## 10 x 10 "dtCMatrix"
stopifnot( all(sA == tA + t(tA)) ,
            identical(sA, as(tA + t(tA), "symmetricMatrix")))

## dims can be larger than the maximum row or column indices
(AA <- sparseMatrix(c(1,3:8), c(2,9,6:10), x = 7 * (1:7), dims = c(10,20)))
summary(AA)

## i, j and x can be in an arbitrary order, as long as they are consistent
set.seed(1); (perm <- sample(1:7))
(A1 <- sparseMatrix(i[perm], j[perm], x = x[perm]))
stopifnot(identical(A, A1))

## The slots are 0-index based, so
try( sparseMatrix(i=A@i, p=A@p, x= seq_along(A@x)) )
## fails and you should say so: 1-indexing is FALSE:
sparseMatrix(i=A@i, p=A@p, x= seq_along(A@x), index1 = FALSE)

## the (i,j) pairs can be repeated, in which case the x's are summed
(args <- data.frame(i = c(i, 1), j = c(j, 2), x = c(x, 2)))
(Aa <- do.call(sparseMatrix, args))
## explicitly ask for elimination of such duplicates, so
## that the last one is used:
(A. <- do.call(sparseMatrix, c(args, list(use.last.ij = TRUE))))
```

```

stopifnot(Aa[1,2] == 9, # 2+7 == 9
          A.[1,2] == 2) # 2 was *after* 7

## for a pattern matrix, of course there is no "summing":
(nA <- do.call(sparseMatrix, args[c("i","j")]))

dn <- list(LETTERS[1:3], letters[1:5])
## pointer vectors can be used, and the (i,x) slots are sorted if necessary:
m <- sparseMatrix(i = c(3,1, 3:2, 2:1), p = c(0:2, 4,4,6), x = 1:6, dimnames = dn)
m
str(m)
stopifnot(identical(dimnames(m), dn))

sparseMatrix(x = 2.72, i=1:3, j=2:4) # recycling x
sparseMatrix(x = TRUE, i=1:3, j=2:4) # recycling x, |--> "lgCMatrix"

## no 'x' --> patter*n* matrix:
(n <- sparseMatrix(i=1:6, j=rev(2:7)))# -> ngCMatrix

## an empty sparse matrix:
(e <- sparseMatrix(dims = c(4,6), i={}, j={}))

## a symmetric one:
(sy <- sparseMatrix(i= c(2,4,3:5), j= c(4,7:5,5), x = 1:5,
                    dims = c(7,7), symmetric=TRUE))
stopifnot(isSymmetric(sy),
          identical(sy, ## switch i <-> j {and transpose }
                    t( sparseMatrix(j= c(2,4,3:5), i= c(4,7:5,5), x = 1:5,
                                   dims = c(7,7), symmetric=TRUE))))

## rsparsematrix() calls sparseMatrix() :
M1 <- rsparsematrix(1000, 20, nnz = 200)
summary(M1)

## pointers example in converting from other sparse matrix representations.
if(requireNamespace("SparseM") &&
    packageVersion("SparseM") >= "0.87" &&
    nzchar(dfil <- system.file("extdata", "rua_32_ax.rua", package = "SparseM"))) {
  X <- SparseM::model.matrix(SparseM::read.matrix.hb(dfil))
  XX <- sparseMatrix(j = X@ja, p = X@ia - 1L, x = X@ra, dims = X@dimension)
  validObject(XX)

  ## Alternatively, and even more user friendly :
  X. <- as(X, "Matrix") # or also
  X2 <- as(X, "sparseMatrix")
  stopifnot(identical(XX, X.), identical(X., X2))
}

```

---

sparseMatrix-class *Virtual Class "sparseMatrix" — Mother of Sparse Matrices*

---

## Description

Virtual Mother Class of All Sparse Matrices

## Slots

**Dim:** Object of class "integer" - the dimensions of the matrix - must be an integer vector with exactly two non-negative values.

**Dimnames:** a list of length two - inherited from class `Matrix`, see [Matrix](#).

## Extends

Class "Matrix", directly.

## Methods

**show** (object = "sparseMatrix"): The `show` method for sparse matrices prints “*structural*” zeroes as " ." using `printSpMatrix()` which allows further customization.

**print** signature(x = "sparseMatrix"), ...

The `print` method for sparse matrices by default is the same as `show()` but can be called with extra optional arguments, see `printSpMatrix()`.

**format** signature(x = "sparseMatrix"), ...

The `format` method for sparse matrices, see `formatSpMatrix()` for details such as the extra optional arguments.

**summary** (object = "sparseMatrix", uniqT=FALSE): Returns an object of S3 class "sparseSummary" which is basically a `data.frame` with columns (i, j, x) (or just (i, j) for `nsparseMatrix` class objects) with the stored (typically non-zero) entries. The `print` method resembles Matlab’s way of printing sparse matrices, and also the `MatrixMarket` format, see `writeMM`.

**cbind2** (x = \*, y = \*): several methods for binding matrices together, column-wise, see the basic `cbind` and `rbind` functions.

Note that the result will typically be sparse, even when one argument is dense and larger than the sparse one.

**rbind2** (x = \*, y = \*): binding matrices together row-wise, see `cbind2` above.

**determinant** (x = "sparseMatrix", logarithm=TRUE): `determinant()` methods for sparse matrices typically work via `Cholesky` or `lu` decompositions.

**diag** (x = "sparseMatrix"): extracts the diagonal of a sparse matrix.

**dim<-** signature(x = "sparseMatrix", value = "ANY"): allows to *reshape* a sparse matrix to a sparse matrix with the same entries but different dimensions. `value` must be of length two and fulfill `prod(value) == prod(dim(x))`.

**coerce** signature(from = "factor", to = "sparseMatrix"): Coercion of a factor to "sparseMatrix" produces the matrix of indicator **rows** stored as an object of class "dgCMatrix". To obtain columns representing the interaction of the factor and a numeric covariate, replace the "x" slot of the result by the numeric covariate then take the transpose. Missing values ([NA](#)) from the factor are translated to columns of all 0s.

See also `colSums`, `norm`, ... for methods with separate help pages.

## Note

In method selection for multiplication operations (i.e. `%*%` and the two-argument form of `crossprod`) the `sparseMatrix` class takes precedence in the sense that if one operand is a sparse matrix and the other is any type of dense matrix then the dense matrix is coerced to a `dgeMatrix` and the appropriate sparse matrix method is used.

**See Also**

`sparseMatrix`, and its references, such as `xtabs(*, sparse=TRUE)`, or `sparse.model.matrix()`, for constructing sparse matrices.

`T2graph` for conversion of "graph" objects (package **graph**) to and from sparse matrices.

**Examples**

```
showClass("sparseMatrix") ## and look at the help() of its subclasses
M <- Matrix(0, 10000, 100)
M[1,1] <- M[2,3] <- 3.14
M ## show(.) method suppresses printing of the majority of rows

data(CAex, package = "Matrix")
dim(CAex) # 72 x 72 matrix
determinant(CAex) # works via sparse lu(.)

## factor -> t( <sparse design matrix> ) :
(fact <- gl(5, 3, 30, labels = LETTERS[1:5]))
(Xt <- as(fact, "sparseMatrix")) # indicator rows

## missing values --> all-0 columns:
f.mis <- fact
i.mis <- c(3:5, 17)
is.na(f.mis) <- i.mis
Xt != (X. <- as(f.mis, "sparseMatrix")) # differ only in columns 3:5,17
stopifnot(all(X.[,i.mis] == 0), all(Xt[, -i.mis] == X.[, -i.mis]))
```

---

sparseQR-class

*Sparse QR Factorizations*

---

**Description**

`sparseQR` is the class of sparse, row- and column-pivoted QR factorizations of  $m \times n$  ( $m \geq n$ ) real matrices, having the general form

$$P_1 A P_2 = Q R = \begin{bmatrix} Q_1 & Q_2 \end{bmatrix} \begin{bmatrix} R_1 \\ 0 \end{bmatrix} = Q_1 R_1$$

or (equivalently)

$$A = P_1' Q R P_2' = P_1' \begin{bmatrix} Q_1 & Q_2 \end{bmatrix} \begin{bmatrix} R_1 \\ 0 \end{bmatrix} P_2' = P_1' Q_1 R_1 P_2'$$

where  $P_1$  and  $P_2$  are permutation matrices,  $Q = \prod_{j=1}^n H_j$  is an  $m \times m$  orthogonal matrix ( $Q_1$  contains the first  $n$  column vectors) equal to the product of  $n$  Householder matrices  $H_j$ , and  $R$  is an  $m \times n$  upper trapezoidal matrix ( $R_1$  contains the first  $n$  row vectors and is upper *triangular*).

**Usage**

```
qrR(qr, complete = FALSE, backPermute = TRUE, row.names = TRUE)
```

## Arguments

|                          |  |
|--------------------------|--|
| <code>qr</code>          | an object of class <code>sparseQR</code> , almost always the result of a call to generic function <code>qr</code> with sparse <code>x</code> .                                 |
| <code>complete</code>    | a logical indicating if $R$ should be returned instead of $R_1$ .  |
| <code>backPermute</code> | a logical indicating if $R$ or $R_1$ should be multiplied on the right by $P_2'$ .   |
| <code>row.names</code>   | a logical indicating if <code>dimnames(qr)[1]</code> should be propagated unpermuted to the result. If <code>complete = FALSE</code> , then only the first $n$ names are kept. |

## Details

The method for `qr.Q` does not return  $Q$  but rather the (also orthogonal) product  $P_1'Q$ . This behaviour is algebraically consistent with the **base** implementation (see `qr`), which can be seen by noting that `qr.default` in **base** does not pivot rows, constraining  $P_1$  to be an identity matrix. It follows that `qr.Q(qr.default(x))` also returns  $P_1'Q$ .

Similarly, the methods for `qr.qy` and `qr.qty` multiply on the left by  $P_1'Q$  and  $Q'P_1$  rather than  $Q$  and  $Q'$ .

It is wrong to expect the values of `qr.Q` (or `qr.R`, `qr.qy`, `qr.qty`) computed from “equivalent” sparse and dense factorizations (say, `qr(x)` and `qr(as(x, "matrix"))` for `x` of class `dgCMatrix`) to compare equal. The underlying factorization algorithms are quite different, notably as they employ different pivoting strategies, and in general the factorization is not unique even for fixed  $P_1$  and  $P_2$ .

On the other hand, the values of `qr.X`, `qr.coef`, `qr.fitted`, and `qr.resid` are well-defined, and in those cases the sparse and dense computations *should* compare equal (within some tolerance).

The method for `qr.R` is a simple wrapper around `qrR`, but not back-permuting by default and never giving row names. It did not support `backPermute = TRUE` until **Matrix** 1.6-0, hence code needing the back-permuted result should call `qrR` if **Matrix**  $\geq$  1.6-0 is not known.

## Slots

`Dim`, `Dimnames` inherited from virtual class `MatrixFactorization`.

`beta` a numeric vector of length `Dim[2]`, used to construct Householder matrices; see `V` below.

`V` an object of class `dgCMatrix` with `Dim[2]` columns. The number of rows `nrow(V)` is at least `Dim[1]` and at most `Dim[1]+Dim[2]`. `V` is lower trapezoidal, and its column vectors generate the Householder matrices  $H_j$  that compose the orthogonal  $Q$  factor. Specifically,  $H_j$  is constructed as `diag(Dim[1]) - beta[j] * tcrossprod(V[, j])`.

`R` an object of class `dgCMatrix` with `nrow(V)` rows and `Dim[2]` columns. `R` is the upper trapezoidal  $R$  factor.

`p`, `q` 0-based integer vectors of length `nrow(V)` and `Dim[2]`, respectively, specifying the permutations applied to the rows and columns of the factorized matrix. `q` of length 0 is valid and equivalent to the identity permutation, implying no column pivoting. Using `R` syntax, the matrix  $P_1AP_2$  is precisely `A[p+1, q+1]` (`A[p+1, ]` when `q` has length 0).

## Extends

Class `QR`, directly. Class `MatrixFactorization`, by class `QR`, distance 2.

## Instantiation

Objects can be generated directly by calls of the form `new("sparseQR", ...)`, but they are more typically obtained as the value of `qr(x)` for `x` inheriting from `sparseMatrix` (often `dgCMatrix`).

## Methods

`determinant` signature(`from` = "sparseQR", `logarithm` = "logical"): computes the determinant of the factorized matrix  $A$  or its logarithm.

`expand1` signature(`x` = "sparseQR"): see [expand1-methods](#).

`expand2` signature(`x` = "sparseQR"): see [expand2-methods](#).

`qr.Q` signature(`qr` = "sparseQR"): returns as a [dgeMatrix](#) either  $P_1'Q$  or  $P_1'Q_1$ , depending on optional argument `complete`. The default is FALSE, indicating  $P_1'Q_1$ .

`qr.R` signature(`qr` = "sparseQR"): `qrR` returns  $R$ ,  $R_1$ ,  $RP_2'$ , or  $R_1P_2'$ , depending on optional arguments `complete` and `backPermute`. The default in both cases is FALSE, indicating  $R_1$ , for compatibility with **base**. The class of the result in that case is [dtCMatrix](#). In the other three cases, it is [dgCMatrix](#).

`qr.X` signature(`qr` = "sparseQR"): returns  $A$  as a [dgeMatrix](#), by default. If  $m > n$  and optional argument `ncol` is greater than  $n$ , then the result is augmented with  $P_1'QJ$ , where  $J$  is composed of columns  $(n + 1)$  through `ncol` of the  $m \times m$  identity matrix.

`qr.coef` signature(`qr` = "sparseQR", `y` = .): returns as a [dgeMatrix](#) or vector the result of multiplying  $y$  on the left by  $P_2R_1^{-1}Q_1'P_1$ .

`qr.fitted` signature(`qr` = "sparseQR", `y` = .): returns as a [dgeMatrix](#) or vector the result of multiplying  $y$  on the left by  $P_1'Q_1Q_1'P_1$ .

`qr.resid` signature(`qr` = "sparseQR", `y` = .): returns as a [dgeMatrix](#) or vector the result of multiplying  $y$  on the left by  $P_1'Q_2Q_2'P_1$ .

`qr.qty` signature(`qr` = "sparseQR", `y` = .): returns as a [dgeMatrix](#) or vector the result of multiplying  $y$  on the left by  $Q'P_1$ .

`qr.qy` signature(`qr` = "sparseQR", `y` = .): returns as a [dgeMatrix](#) or vector the result of multiplying  $y$  on the left by  $P_1'Q$ .

`solve` signature(`a` = "sparseQR", `b` = .): see [solve-methods](#).

---

sparseVector

---

*Sparse Vector Construction from Nonzero Entries*

---

## Description

User friendly construction of sparse vectors, i.e., objects inheriting from `class sparseVector`, from indices and values of its non-zero entries.

## Usage

```
sparseVector(x, i, length)
```

## Arguments

|                     |   |
|---------------------|---|
| <code>x</code>      | vector of the non zero entries; may be missing in which case a "nsparseVector" will be returned.  |
| <code>i</code>      | integer vector (of the same length as <code>x</code> ) specifying the indices of the non-zero (or non-TRUE) entries of the sparse vector. |
| <code>length</code> | length of the sparse vector.  |

## Details

zero entries in `x` are dropped automatically, analogously as `drop0()` acts on sparse matrices.

## Value

a sparse vector, i.e., inheriting from `class sparseVector`.

## Author(s)

Martin Maechler

**See Also**

`sparseMatrix()` constructor for sparse matrices; the class `sparseVector`.

**Examples**

```
str(sv <- sparseVector(x = 1:10, i = sample(999, 10), length=1000))

sx <- c(0,0,3, 3.2, 0,0,0,-3:1,0,0,2,0,0,5,0,0)
ss <- as(sx, "sparseVector")
stopifnot(identical(ss,
  sparseVector(x = c(2, -1, -2, 3, 1, -3, 5, 3.2),
    i = c(15L, 10:9, 3L,12L,8L,18L, 4L), length = 20L)))

(ns <- sparseVector(i= c(7, 3, 2), length = 10))
stopifnot(identical(ns,
  new("nsparseVector", length = 10, i = c(2, 3, 7))))
```

---

sparseVector-class *Sparse Vector Classes*

---

**Description**

**Sparse Vector Classes:** The virtual mother class "sparseVector" has the five actual daughter classes "dsparseVector", "isparseVector", "lsparseVector", "nsparseVector", and "zsparseVector", where we've mainly implemented methods for the `d*`, `l*` and `n*` ones.

**Slots**

- length:** class "numeric" - the `length` of the sparse vector. Note that "numeric" can be considerably larger than the maximal "integer", `.Machine$integer.max`, on purpose.
- i:** class "numeric" - the (1-based) indices of the non-zero entries. Must *not* be NA and strictly sorted increasingly.  
Note that "integer" is "part of" "numeric", and can (and often will) be used for non-huge sparseVectors.
- x:** (for all but "nsparseVector"): the non-zero entries. This is of class "numeric" for class "dsparseVector", "logical" for class "lsparseVector", etc.

**Methods**

- length** signature (`x = "sparseVector"`): simply extracts the length slot.
- show** signature (`object = "sparseVector"`): The `show` method for sparse vectors prints "structural" zeroes as "." using the non-exported `prSpVector` function which allows further customization such as replacing "." by " " (blank).  
Note that `options(max.print)` will influence how many entries of large sparse vectors are printed at all.
- as.vector** signature (`x = "sparseVector", mode = "character"`) coerces sparse vectors to "regular", i.e., atomic vectors. This is the same as `as(x, "vector")`.
- as** ..: see coerce below

**coerce** signature (from = "sparseVector", to = "sparseMatrix"), and

**coerce** signature (from = "sparseMatrix", to = "sparseVector"), etc: coercions to and from sparse matrices ([sparseMatrix](#)) are provided and work analogously as in standard R, i.e., a vector is coerced to a 1-column matrix.

**dim<-** signature (x = "sparseVector", value = "integer") coerces a sparse vector to a sparse Matrix, i.e., an object inheriting from [sparseMatrix](#), of the appropriate dimension.

**head** signature (x = "sparseVector"): as with R's (package [util](#)) [head](#), `head(x, n)` (for  $n \geq 1$ ) is equivalent to `x[1:n]`, but here can be much more efficient, see the example.

**tail** signature (x = "sparseVector"): analogous to [head](#), see above.

**toeplitz** signature (x = "sparseVector"): as [toeplitz](#)(x), produce the  $n \times n$  Toeplitz matrix from x, where  $n = \text{length}(x)$ .

**rep** signature (x = "sparseVector") repeat x, with the same argument list (x, times, length.out, each, ...) as the default method for `rep()`.

**which** signature (x = "nsparseVector") and

**which** signature (x = "lsparseVector") return the indices of the non-zero entries (which is trivial for sparse vectors).

**Ops** signature (e1 = "sparseVector", e2 = "\*"): define arithmetic, compare and logic operations, (see [Ops](#)).

**Summary** signature (x = "sparseVector"): define all the [Summary](#) methods.

**is.na, is.finite, is.infinite** (x = "sparseVector"), and

**is.na, is.finite, is.infinite** (x = "nsparseVector"): return [logical](#) or "nsparseVector" of the same length as x, indicating if/where x is [NA](#) (or NaN), finite or infinite, entirely analogously to the corresponding base R functions.

**zapsmall** signature (x = "sparseVectors"): typically used for numeric sparse vector: [round\(\)](#) entries such that (relatively) very small entries become zero exactly.

`c.sparseVector()` is an S3 method for all "sparseVector"s, but automatic dispatch only happens for the first argument, so it is useful also as regular R function, see the examples.

## See Also

[sparseVector\(\)](#) for friendly construction of sparse vectors (apart from `as(*, "sparseVector")`).

## Examples

```
getClass("sparseVector")
getClass("dsparseVector")

sx <- c(0,0,3, 3.2, 0,0,0,-3:1,0,0,2,0,0,5,0,0)
(ss <- as(sx, "sparseVector"))

ix <- as.integer(round(sx))
(is <- as(ix, "sparseVector")) ## an "isparseVector" (!)
(ns <- sparseVector(i=c(7, 3, 2), length = 10)) # "nsparseVector"
## rep() works too:
(ri <- rep(is, length.out= 25))

## Using `dim<-` as in base R :
r <- ss
```

```

dim(r) <- c(4,5) # becomes a sparse Matrix:
r
## or coercion (as as.matrix() in base R):
as(ss, "Matrix")
stopifnot(all(ss == print(as(ss, "CsparseMatrix"))))

## currently has "non-structural" FALSE -- printing as ":"
(lis <- is & FALSE)
(nn <- is[is == 0]) # all "structural" FALSE

## NA-case
sN <- sx; sN[4] <- NA
(svN <- as(sN, "sparseVector"))

v <- as(c(0,0,3, 3.2, rep(0,9),-3,0,-1, rep(0,20),5,0),
        "sparseVector")
v <- rep(rep(v, 50), 5000)
set.seed(1); v[sample(v@i, 1e6)] <- 0
str(v)
system.time(for(i in 1:4) hv <- head(v, 1e6))
##   user   system elapsed
## 0.033    0.000    0.032
system.time(for(i in 1:4) h2 <- v[1:1e6])
##   user   system elapsed
## 1.317    0.000    1.319

stopifnot(identical(hv, h2),
           identical(is | FALSE, is != 0),
           validObject(svN), validObject(lis), as.logical(is.na(svN[4])),
           identical(is^2 > 0, is & TRUE),
           all(!lis), !any(lis), length(nn@i) == 0, !any(nn), all(!nn),
           sum(lis) == 0, !prod(lis), range(lis) == c(0,0))

## create and use the t(.) method:
t(x20 <- sparseVector(c(9,3:1), i=c(1:2,4,7), length=20))
(T20 <- toeplitz(x20))
stopifnot(is(T20, "symmetricMatrix"), is(T20, "sparseMatrix"),
           identical(unname(as.matrix(T20)),
                     toeplitz(as.vector(x20))))

## c() method for "sparseVector" - also available as regular function
(c1 <- c(x20, 0,0,0, -10*x20))
(c2 <- c(ns, is, FALSE))
(c3 <- c(ns, !ns, TRUE, NA, FALSE))
(c4 <- c(ns, rev(ns)))
## here, c() would produce a list {not dispatching to c.sparseVector()}
(c5 <- c.sparseVector(0,0, x20))

## checking (consistency)
.v <- as.vector
.s <- function(v) as(v, "sparseVector")
stopifnot(exprs = {
  all.equal(c1, .s(c(.v(x20), 0,0,0, -10*.v(x20))),      tol = 0)
  all.equal(c2, .s(c(.v(ns), .v(is), FALSE)),           tol = 0)
  all.equal(c3, .s(c(.v(ns), !.v(ns), TRUE, NA, FALSE)), tol = 0)
  all.equal(c4, .s(c(.v(ns), rev(.v(ns)))),             tol = 0,
            check.class = FALSE)
})

```

```
all.equal(c5, .s(c(0,0, .v(x20))), tol = 0)
})
```

spMatrix

*Sparse Matrix Constructor From Triplet*

## Description

User friendly construction of a sparse matrix (inheriting from class [TsparseMatrix](#)) from the triplet representation.

This is much less flexible than [sparseMatrix\(\)](#) and hence somewhat *deprecated*.

## Usage

```
spMatrix(nrow, ncol, i = integer(0L), j = integer(0L), x = double(0L))
```

## Arguments

|            |  |
|------------|--|
| nrow, ncol | integers specifying the desired number of rows and columns.  |
| i, j       | integer vectors of the same length specifying the locations of the non-zero (or non-TRUE) entries of the matrix. |
| x          | atomic vector of the same length as i and j, specifying the values of the non-zero entries.                      |

## Value

A sparse matrix in triplet form, as an R object inheriting from both [TsparseMatrix](#) and [generalMatrix](#).

The matrix  $M$  will have  $M[i[k], j[k]] == x[k]$ , for  $k = 1, 2, \dots, n$ , where  $n = \text{length}(i)$  and  $M[i', j'] == 0$  for all other pairs  $(i', j')$ .

## See Also

[Matrix\(\\*, sparse=TRUE\)](#) for the more usual constructor of such matrices. Then, [sparseMatrix](#) is more general and flexible than [spMatrix\(\)](#) and by default returns a [CsparseMatrix](#) which is often slightly more desirable. Further, [bdiag](#) and [Diagonal](#) for (block-)diagonal matrix constructors.

Consider [TsparseMatrix](#) and similar class definition help files.

## Examples

```
## simple example
A <- spMatrix(10,20, i = c(1,3:8),
               j = c(2,9,6:10),
               x = 7 * (1:7))

A # a "dgTMatrix"
summary(A)
str(A) # note that *internally* 0-based indices (i,j) are used

L <- spMatrix(9, 30, i = rep(1:9, 3), 1:27,
              (1:27) %% 4 != 1)
```

```

L # an "lgTMatrix"

## A simplified predecessor of Matrix' rsparsematrix() function :

rSpMatrix <- function(nrow, ncol, nnz,
                      rand.x = function(n) round(rnorm(nnz), 2))
{
  ## Purpose: random sparse matrix
  ## -----
  ## Arguments: (nrow,ncol): dimension
  ##           nnz : number of non-zero entries
  ##           rand.x: random number generator for 'x' slot
  ## -----
  ## Author: Martin Maechler, Date: 14.-16. May 2007
  stopifnot((nnz <- as.integer(nnz)) >= 0,
            nrow >= 0, ncol >= 0, nnz <= nrow * ncol)
  spMatrix(nrow, ncol,
           i = sample(nrow, nnz, replace = TRUE),
           j = sample(ncol, nnz, replace = TRUE),
           x = rand.x(nnz))
}

M1 <- rSpMatrix(100000, 20, nnz = 200)
summary(M1)

```

---

subassign-methods    *Methods for "[<-" - Assigning to Subsets for 'Matrix'*

---

## Description

Methods for "[<-", i.e., extraction or subsetting mostly of matrices, in package **Matrix**.

**Note:** Contrary to standard `matrix` assignment in base R, in `x[. .] <- val` it is typically an **error** (see [stop](#)) when the **type** or **class** of `val` would require the class of `x` to be changed, e.g., when `x` is logical, say `"lsparseMatrix"`, and `val` is numeric. In other cases, e.g., when `x` is a `"nsparseMatrix"` and `val` is not TRUE or FALSE, a warning is signalled, and `val` is “interpreted” as [logical](#), and (logical) [NA](#) is interpreted as TRUE.

## Methods

There are *many many* more than these:

`x = "Matrix", i = "missing", j = "missing", value = "ANY"` is currently a simple fallback method implementation which ensures “readable” error messages.

`x = "Matrix", i = "ANY", j = "ANY", value = "ANY"` currently gives an error

`x = "denseMatrix", i = "index", j = "missing", value = "numeric" ...`

`x = "denseMatrix", i = "index", j = "index", value = "numeric" ...`

`x = "denseMatrix", i = "missing", j = "index", value = "numeric" ...`

## See Also

[\[-methods](#) for subsetting "Matrix" objects; the [index](#) class; [Extract](#) about the standard subset assignment (and extraction).

**Examples**

```

set.seed(101)
(a <- m <- Matrix(round(rnorm(7*4),2), nrow = 7))

a[] <- 2.2 # <- replaces every entry
a
## as do these:
a[,] <- 3 ; a[TRUE,] <- 4

m[2, 3] <- 3.14 # simple number
m[3, 3:4] <- 3:4 # simple numeric of length 2

## sub matrix assignment:
m[-(4:7), 3:4] <- cbind(1,2:4) #-> upper right corner of 'm'
m[3:5, 2:3] <- 0
m[6:7, 1:2] <- Diagonal(2)
m

## rows or columns only:
m[1,] <- 10
m[,2] <- 1:7
m[-(1:6), ] <- 3:0 # not the first 6 rows, i.e. only the 7th
as(m, "sparseMatrix")

```

---

subscript-methods    *Methods for "[": Extraction or Subsetting in Package 'Matrix'*

---

**Description**

Methods for "[", i.e., extraction or subsetting mostly of matrices, in package **Matrix**.

**Methods**

There are more than these:

```

x = "Matrix", i = "missing", j = "missing", drop= "ANY" ...
x = "Matrix", i = "numeric", j = "missing", drop= "missing" ...
x = "Matrix", i = "missing", j = "numeric", drop= "missing" ...
x = "dsparseMatrix", i = "missing", j = "numeric", drop= "logical" ...
x = "dsparseMatrix", i = "numeric", j = "missing", drop= "logical" ...
x = "dsparseMatrix", i = "numeric", j = "numeric", drop= "logical" ...

```

**See Also**

[\[<--methods](#) for subassignment to "Matrix" objects. [Extract](#) about the standard extraction.

**Examples**

```

str(m <- Matrix(round(rnorm(7*4),2), nrow = 7))
stopifnot(identical(m, m[]))
m[2, 3]    # simple number
m[2, 3:4]  # simple numeric of length 2
m[2, 3:4, drop=FALSE] # sub matrix of class 'dgeMatrix'
## rows or columns only:
m[1,]      # first row, as simple numeric vector
m[,1:2]    # sub matrix of first two columns

showMethods("[", inherited = FALSE)

```

---

symmetricMatrix-class

*Virtual Class of Symmetric Matrices in Package Matrix*

---

**Description**

The virtual class of symmetric matrices, "symmetricMatrix", from the package **Matrix** contains numeric and logical, dense and sparse matrices, e.g., see the examples with the “actual” sub-classes.

The main use is in methods (and C functions) that can deal with all symmetric matrices, and in `as(*, "symmetricMatrix")`.

**Slots**

`Dim`, `Dimnames` inherited from virtual class `Matrix`. See comments below about symmetry of `Dimnames`.

`factors` a list of `MatrixFactorization` objects caching factorizations of the matrix. Typically, it is initialized as an empty list and updated “automagically” whenever a factorization is computed.

`uplo` a character string, either "U" or "L" indicating that only entries in the upper or lower triangle are referenced.

**Extends**

Class "Matrix", directly.

**Methods**

**dimnames** signature(object = "symmetricMatrix"): returns *symmetric dimnames*, even when the `Dimnames` slot only has row or column names. This allows to save storage for large (typically sparse) symmetric matrices.

**isSymmetric** signature(object = "symmetricMatrix"): returns TRUE trivially.

There's a C function `symmetricMatrix_validate()` called by the internal validity checking functions, and also from `getValidity(getClass("symmetricMatrix"))`.

**Validity and dimnames**

The validity checks do not require a symmetric `Dimnames` slot, so it can be `list(NULL, <character>)`, e.g., for efficiency. However, `dimnames()` and other functions and methods should behave as if the `dimnames` were symmetric, i.e., with both list components identical.

**See Also**

[isSymmetric](#) which has efficient methods ([isSymmetric-methods](#)) for the **Matrix** classes. Classes [triangularMatrix](#), and, e.g., [dsyMatrix](#) for numeric *dense* matrices, or [lsCMatrix](#) for a logical *sparse* matrix class.

**Examples**

```
## An example about the symmetric Dimnames:
sy <- sparseMatrix(i= c(2,4,3:5), j= c(4,7:5,5), x = 1:5, dims = c(7,7),
                  symmetric=TRUE, dimnames = list(NULL, letters[1:7]))
sy # shows symmetrical dimnames
sy@Dimnames # internally only one part is stored
dimnames(sy) # both parts - as sy *is* symmetrical

showClass("symmetricMatrix")

## The names of direct subclasses:
scl <- getClass("symmetricMatrix")@subclasses
directly <- sapply(lapply(scl, slot, "by"), length) == 0
names(scl)[directly]

## Methods -- applicable to all subclasses above:
showMethods(classes = "symmetricMatrix")
```

---

|                  |  |
|------------------|--|
| symmpart-methods | <i>Symmetric Part and Skew(symmetric) Part of a Matrix</i> |
|------------------|--|

---

**Description**

`symmpart(x)` computes the symmetric part  $(x + t(x)) / 2$  and `skewpart(x)` the skew symmetric part  $(x - t(x)) / 2$  of a square matrix `x`, more efficiently for specific **Matrix** classes.

Note that `x == symmpart(x) + skewpart(x)` for all square matrices – apart from extraneous [NA](#) values in the RHS.

**Usage**

```
symmpart(x)
skewpart(x)
```

**Arguments**

|                |   |
|----------------|---|
| <code>x</code> | a <i>square</i> matrix; either “traditional” of class <code>"matrix"</code> , or typically, inheriting from the <a href="#">Matrix</a> class. |
|----------------|---|

**Details**

These are generic functions with several methods for different matrix classes, use e.g., [showMethods\(symmpart\)](#) to see them.

If the row and column names differ, the result will use the column names unless they are (partly) `NULL` where the row names are non-`NULL` (see also the examples).

**Value**

`symmpart(x)` returns a symmetric matrix, inheriting from `symmetricMatrix` or `diagonalMatrix` if `x` inherits from `Matrix`.

`skewpart(x)` returns a skew-symmetric matrix, inheriting from `generalMatrix`, `symmetricMatrix` or `diagonalMatrix` if `x` inherits from `Matrix`.

**See Also**

`isSymmetric`.

**Examples**

```
m <- Matrix(1:4, 2, 2)
symmpart(m)
skewpart(m)

stopifnot(all(m == symmpart(m) + skewpart(m)))

dn <- dimnames(m) <- list(row = c("r1", "r2"), col = c("var.1", "var.2"))
stopifnot(all(m == symmpart(m) + skewpart(m)))
colnames(m) <- NULL
stopifnot(all(m == symmpart(m) + skewpart(m)))
dimnames(m) <- unname(dn)
stopifnot(all(m == symmpart(m) + skewpart(m)))

## investigate the current methods:
showMethods(skewpart, include = TRUE)
```

---

triangularMatrix-class

*Virtual Class of Triangular Matrices in Package Matrix*

---

**Description**

The virtual class of triangular matrices, "triangularMatrix", the package **Matrix** contains *square* (`nrow == ncol`) numeric and logical, dense and sparse matrices, e.g., see the examples. A main use of the virtual class is in methods (and C functions) that can deal with all triangular matrices.

**Slots**

**uplo:** String (of class "character"). Must be either "U", for upper triangular, and "L", for lower triangular.

**diag:** String (of class "character"). Must be either "U", for unit triangular (diagonal is all ones), or "N" for non-unit. The diagonal elements are not accessed internally when `diag` is "U". For `denseMatrix` classes, they need to be allocated though, such that the length of the `x` slot does not depend on `diag`.

**Dim, Dimnames:** The dimension (a length-2 "integer") and corresponding names (or NULL), inherited from the `Matrix`, see there.

**Extends**

Class "Matrix", directly.

**Methods**

There's a C function `triangularMatrix_validity()` called by the internal validity checking functions.

Currently, `Schur`, `isSymmetric` and `as()` (i.e. `coerce`) have methods with `triangularMatrix` in their signature.

**See Also**

`isTriangular()` for testing any matrix for triangularity; classes `symmetricMatrix`, and, e.g., `dtrMatrix` for numeric *dense* matrices, or `ltcMatrix` for a logical *sparse* matrix subclass of "triangularMatrix".

**Examples**

```
showClass("triangularMatrix")

## The names of direct subclasses:
scl <- getClass("triangularMatrix")@subclasses
directly <- sapply(lapply(scl, slot, "by"), length) == 0
names(scl)[directly]

(m <- matrix(c(5,1,0,3), 2))
as(m, "triangularMatrix")
```

---

TsparseMatrix-class

*Class "TsparseMatrix" of Sparse Matrices in Triplet Form*

---

**Description**

The "TsparseMatrix" class is the virtual class of all sparse matrices coded in triplet form. Since it is a virtual class, no objects may be created from it. See `showClass("TsparseMatrix")` for its subclasses.

**Slots**

Dim, Dimnames: from the "Matrix" class,

i: Object of class "integer" - the row indices of non-zero entries *in 0-base*, i.e., must be in `0:(nrow(.)-1)`.

j: Object of class "integer" - the column indices of non-zero entries. Must be the same length as slot i and *0-based* as well, i.e., in `0:(ncol(.)-1)`. For numeric Tsparse matrices, (i, j) pairs can occur more than once, see `dgTMatrix`.

**Extends**

Class "sparseMatrix", directly. Class "Matrix", by class "sparseMatrix".

## Methods

Extraction ("[") methods, see [\[-methods\]](#).

## Note

Most operations with sparse matrices are performed using the compressed, column-oriented or [CsparseMatrix](#) representation. The triplet representation is convenient for creating a sparse matrix or for reading and writing such matrices. Once it is created, however, the matrix is generally coerced to a [CsparseMatrix](#) for further operations.

Note that all `new()`, [spMatrix](#) and [sparseMatrix](#)(\*, repr="T") constructors for "TsparseMatrix" classes implicitly add (i.e., "sum up")  $x_k$ 's that belong to identical  $(i_k, j_k)$  pairs, see, the example below, or also [dgTMatrix](#).

For convenience, methods for some operations such as `%%` and `crossprod` are defined for [TsparseMatrix](#) objects. These methods simply coerce the [TsparseMatrix](#) object to a [CsparseMatrix](#) object then perform the operation.

## See Also

its superclass, [sparseMatrix](#), and the [dgTMatrix](#) class, for the links to other classes.

## Examples

```
showClass("TsparseMatrix")
## or just the subclasses' names
names(getClass("TsparseMatrix")@subclasses)

T3 <- spMatrix(3,4, i=c(1,3:1), j=c(2,4:2), x=1:4)
T3 # only 3 non-zero entries, 5 = 1+4 !
```

---

unpackedMatrix-class

*Virtual Class "unpackedMatrix" of Unpacked Dense Matrices*

---

## Description

Class "unpackedMatrix" is the *virtual* class of dense matrices in "unpacked" format, storing all  $m \times n$  elements of an  $m$ -by- $n$  matrix. It is used to define common methods for efficient subsetting, transposing, etc. of its *proper* subclasses: currently "[\[dln\]geMatrix](#)" (unpacked general), "[\[dln\]syMatrix](#)" (unpacked symmetric), "[\[dln\]trMatrix](#)" (unpacked triangular), and subclasses of these, such as "[dpoMatrix](#)".

## Slots

Dim, Dimnames: as all [Matrix](#) objects.

## Extends

Class "[denseMatrix](#)", directly. Class "[Matrix](#)", by class "[denseMatrix](#)", distance 2.

**Methods**

```

pack signature(x = "unpackedMatrix"): ...
unpack signature(x = "unpackedMatrix"): ...
isSymmetric signature(object = "unpackedMatrix"): ...
isTriangular signature(object = "unpackedMatrix"): ...
isDiagonal signature(object = "unpackedMatrix"): ...
t signature(x = "unpackedMatrix"): ...
diag signature(x = "unpackedMatrix"): ...
diag<- signature(x = "unpackedMatrix"): ...

```

**Author(s)**

Mikael Jagan

**See Also**

`pack` and `unpack`; its virtual "complement" `"packedMatrix"`; its proper subclasses `"dsyMatrix"`, `"ltrMatrix"`, etc.

**Examples**

```

showClass("unpackedMatrix")
showMethods(classes = "unpackedMatrix")

```

---

updown-methods

*Updating and Downdating Sparse Cholesky Factorizations*

---

**Description**

Computes a rank- $k$  update or downdate of a sparse Cholesky factorization

$$P_1 A P_1' = L_1 D L_1' = L L'$$

which for some  $k$ -column matrix  $C$  is the factorization

$$P_1 (A + s C C') P_1' = \tilde{L}_1 \tilde{D} \tilde{L}_1' = \tilde{L} \tilde{L}'$$

Here,  $s = 1$  for an update and  $s = -1$  for a downdate.

**Usage**

```
updown(update, C, L)
```

**Arguments**

|        |   |
|--------|---|
| update | a logical (TRUE or FALSE) or character ("+" or "-") indicating if <code>L</code> should be updated (or otherwise downdated).          |
| C      | a <a href="#">finite</a> matrix or <a href="#">Matrix</a> such that <code>tcrossprod(C)</code> has the dimensions of <code>L</code> . |
| L      | an object of class <a href="#">dCHMsimpl</a> or <a href="#">dCHMsuper</a> specifying a sparse Cholesky factorization.                 |

**Value**

A sparse Cholesky factorization with dimensions matching `L`, typically of class `dCHMsimpl`.

**Author(s)**

Initial implementation by Nicholas Nagle, University of Tennessee.

**References**

Davis, T. A., Hager, W. W. (2001). Multiple-rank modifications of a sparse Cholesky factorization. *SIAM Journal on Matrix Analysis and Applications*, 22(4), 997-1013. doi:10.1137/S0895479899357346

**See Also**

Classes `dCHMsimpl` and `dCHMsupper` and their methods, notably for generic function `update`, which is *not* equivalent to `updown(update = TRUE)`.

Generic function `Cholesky`.

**Examples**

```
m <- sparseMatrix(i = c(3, 1, 3:2, 2:1), p = c(0:2, 4, 4, 6), x = 1:6,
                  dimnames = list(LETTERS[1:3], letters[1:5]))
uc0 <- Cholesky(A <- crossprod(m) + Diagonal(5))
uc1 <- updown("+", Diagonal(5, 1), uc0)
uc2 <- updown("-", Diagonal(5, 1), uc1)
stopifnot(all.equal(uc0, uc2))
```

---

USCounties

Contiguity Matrix of U.S. Counties

---

**Description**

This matrix gives the contiguities of 3111 U.S. counties, using the queen criterion of at least one shared vertex or edge.

**Usage**

```
data(USCounties)
```

**Format**

A  $3111 \times 3111$  sparse, symmetric matrix of class `dsCMatrix`, with 9101 nonzero entries.

## Source

GAL lattice file ‘usc\_q.GAL’ (retrieved in 2008 from ‘<http://sal.uiuc.edu/weights/zips/usc.zip>’ with permission from Luc Anselin for use and distribution) was read into R using function `read.gal` from package **spdep**.

Neighbour lists were augmented with row-standardized (and then symmetrized) spatial weights, using functions `nb2listw` and `similar.listw` from packages **spdep** and **spatialreg**. The resulting `listw` object was coerced to class `dsTMatrix` using `as_dsTMatrix_listw` from **spatialreg**, and subsequently to class `dsCMatrix`.

## References

Ord, J. K. (1975). Estimation methods for models of spatial interaction. *Journal of the American Statistical Association*, 70(349), 120-126. doi:[10.2307/2285387](https://doi.org/10.2307/2285387)

## Examples

```
data(USCounties, package = "Matrix")
(n <- ncol(USCounties))
I <- .symDiagonal(n)

set.seed(1)
r <- 50L
rho <- 1 / runif(r, 0, 0.5)

system.time(MJ0 <- sapply(rho, function(mult)
  determinant(USCounties + mult * I, logarithm = TRUE)$modulus))

## Can be done faster by updating the Cholesky factor:

C1 <- Cholesky(USCounties, Imult = 2)
system.time(MJ1 <- sapply(rho, function(mult)
  determinant(update(C1, USCounties, mult), sqrt = FALSE)$modulus))
stopifnot(all.equal(MJ0, MJ1))

C2 <- Cholesky(USCounties, super = TRUE, Imult = 2)
system.time(MJ2 <- sapply(rho, function(mult)
  determinant(update(C2, USCounties, mult), sqrt = FALSE)$modulus))
stopifnot(all.equal(MJ0, MJ2))
```

---

wrld\_1deg

Contiguity Matrix of World One-Degree Grid Cells

---

## Description

This matrix gives the contiguities of 15260 one-degree grid cells of world land areas, using a criterion based on the great-circle distance between centers.

## Usage

```
data(wrld_1deg)
```

## Format

A  $15260 \times 15260$  sparse, symmetric matrix of class `dsCMatrix`, with 55973 nonzero entries.

## Source

Shoreline data were read into R from the GSHHS database using function `Rgshhs` from package **maptools**. Antarctica was excluded. An approximately one-degree grid was generated using function `Sobj_SpatialGrid`, also from **maptools**. Grid cells with centers on land were identified using the `over` method for classes `SpatialPolygons` and `SpatialGrid`, defined in package **sp**. Neighbours of these were identified by passing the resulting `SpatialPixels` object to function `dnearneigh` from package **spdep**, using as a cut-off a great-circle distance of  $\sqrt{2}$  kilometers between centers.

Neighbour lists were augmented with row-standardized (and then symmetrized) spatial weights, using functions `nb2listw` and `similar.listw` from packages **spdep** and **spatialreg**. The resulting `listw` object was coerced to class `dsTMatrix` using `as_dsTMatrix_listw` from **spatialreg**, and subsequently to class `dsCMatrix`.

## References

Ord, J. K. (1975). Estimation methods for models of spatial interaction. *Journal of the American Statistical Association*, 70(349), 120-126. doi:10.2307/2285387

## Examples

```
data(wrlld_1deg, package = "Matrix")
(n <- ncol(wrlld_1deg))
I <- .symDiagonal(n)

doExtras <- interactive() || nzchar(Sys.getenv("R_MATRIX_CHECK_EXTRA"))
set.seed(1)
r <- if(doExtras) 20L else 3L
rho <- 1 / runif(r, 0, 0.5)

system.time(MJ0 <- sapply(rho, function(mult)
  determinant(wrlld_1deg + mult * I, logarithm = TRUE)$modulus))

## Can be done faster by updating the Cholesky factor:

C1 <- Cholesky(wrlld_1deg, Imult = 2)
system.time(MJ1 <- sapply(rho, function(mult)
  determinant(update(C1, wrlld_1deg, mult), sqrt = FALSE)$modulus))
stopifnot(all.equal(MJ0, MJ1))

C2 <- Cholesky(wrlld_1deg, super = TRUE, Imult = 2)
system.time(MJ2 <- sapply(rho, function(mult)
  determinant(update(C2, wrlld_1deg, mult), sqrt = FALSE)$modulus))
stopifnot(all.equal(MJ0, MJ2))
```

## Chapter 18

# The boot package

---

`abc.ci`

*Nonparametric ABC Confidence Intervals*

---

### Description

Calculate equi-tailed two-sided nonparametric approximate bootstrap confidence intervals for a parameter, given a set of data and an estimator of the parameter, using numerical differentiation.

### Usage

```
abc.ci(data, statistic, index=1, strata=rep(1, n), conf=0.95,
       eps=0.001/n, ...)
```

### Arguments

|                        |   |
|------------------------|---|
| <code>data</code>      | A data set expressed as a vector, matrix or data frame.   |
| <code>statistic</code> | A function which returns the statistic of interest. The function must take at least 2 arguments; the first argument should be the data and the second a vector of weights. The weights passed to <code>statistic</code> will be normalized to sum to 1 within each stratum. Any other arguments should be passed to <code>abc.ci</code> as part of the <code>...{}</code> argument. |
| <code>index</code>     | If <code>statistic</code> returns a vector of length greater than 1, then this indicates the position of the variable of interest within that vector.   |
| <code>strata</code>    | A factor or numerical vector indicating to which sample each observation belongs in multiple sample problems. The default is the one-sample case.   |
| <code>conf</code>      | A scalar or vector containing the confidence level(s) of the required interval(s).  |
| <code>eps</code>       | The value of epsilon to be used for the numerical differentiation.  |
| <code>...</code>       | Any other arguments for <code>statistic</code> . These will be passed unchanged to <code>statistic</code> each time it is called within <code>abc.ci</code> .   |

## Details

This function is based on the function `abcnon` written by R. Tibshirani. A listing of the original function is available in DiCiccio and Efron (1996). The function uses numerical differentiation for the first and second derivatives of the statistic and then uses these values to approximate the bootstrap BCa intervals. The total number of evaluations of the statistic is  $2 \cdot n + 2 + 2 \cdot \text{length}(\text{conf})$  where  $n$  is the number of data points (plus calculation of the original value of the statistic). The function works for the multiple sample case without the need to rewrite the statistic in an artificial form since the stratified normalization is done internally by the function.

## Value

A `length(conf)` by 3 matrix where each row contains the confidence level followed by the lower and upper end-points of the ABC interval at that level.

---

acme*Monthly Excess Returns*

---

**Description**

The `acme` data frame has 60 rows and 3 columns.

The excess return for the Acme Cleveland Corporation are recorded along with those for all stocks listed on the New York and American Stock Exchanges were recorded over a five year period. These excess returns are relative to the return on a risk-less investment such a U.S. Treasury bills.

**Usage**

`acme`

**Format**

This data frame contains the following columns:

`month` A character string representing the month of the observation.

`market` The excess return of the market as a whole.

`acme` The excess return for the Acme Cleveland Corporation.

**Source**

The data were obtained from

Simonoff, J.S. and Tsai, C.-L. (1994) Use of modified profile likelihood for improved tests of constancy of variance in regression. *Applied Statistics*, **43**, 353–370.

**References**

---

aids*Delay in AIDS Reporting in England and Wales*

---

**Description**

The `aids` data frame has 570 rows and 6 columns.

Although all cases of AIDS in England and Wales must be reported to the Communicable Disease Surveillance Centre, there is often a considerable delay between the time of diagnosis and the time that it is reported. In estimating the prevalence of AIDS, account must be taken of the unknown number of cases which have been diagnosed but not reported. The data set here records the reported cases of AIDS diagnosed from July 1983 and until the end of 1992. The data are cross-classified by the date of diagnosis and the time delay in the reporting of the cases.

**Usage**

`aids`

**Format**

This data frame contains the following columns:

`year` The year of the diagnosis.

`quarter` The quarter of the year in which diagnosis was made.

`delay` The time delay (in months) between diagnosis and reporting. 0 means that the case was reported within one month. Longer delays are grouped in 3 month intervals and the value of `delay` is the midpoint of the interval (therefore a value of 2 indicates that reporting was delayed for between 1 and 3 months).

`dud` An indicator of censoring. These are categories for which full information is not yet available and the number recorded is a lower bound only.

`time` The time interval of the diagnosis. That is the number of quarters from July 1983 until the end of the quarter in which these cases were diagnosed.

`y` The number of AIDS cases reported.

**Source**

The data were obtained from

De Angelis, D. and Gilks, W.R. (1994) Estimating acquired immune deficiency syndrome accounting for reporting delay. *Journal of the Royal Statistical Society, A*, **157**, 31–40.

---

aircondit

*Failures of Air-conditioning Equipment*

---

**Description**

Proschan (1963) reported on the times between failures of the air-conditioning equipment in 10 Boeing 720 aircraft. The `aircondit` data frame contains the intervals for the ninth aircraft while `aircondit7` contains those for the seventh aircraft.

Both data frames have just one column. Note that the data have been sorted into increasing order.

**Usage**

`aircondit`

**Format**

The data frames contain the following column:

`hours` The time interval in hours between successive failures of the air-conditioning equipment

**Source**

The data were taken from

Cox, D.R. and Snell, E.J. (1981) *Applied Statistics: Principles and Examples*. Chapman and Hall.

---

amis

*Car Speeding and Warning Signs*

---

## Description

The `amis` data frame has 8437 rows and 4 columns.

In a study into the effect that warning signs have on speeding patterns, Cambridgeshire County Council considered 14 pairs of locations. The locations were paired to account for factors such as traffic volume and type of road. One site in each pair had a sign erected warning of the dangers of speeding and asking drivers to slow down. No action was taken at the second site. Three sets of measurements were taken at each site. Each set of measurements was nominally of the speeds of 100 cars but not all sites have exactly 100 measurements. These speed measurements were taken before the erection of the sign, shortly after the erection of the sign, and again after the sign had been in place for some time.

## Usage

`amis`

## Format

This data frame contains the following columns:

`speed` Speeds of cars (in miles per hour).

`period` A numeric column indicating the time that the reading was taken. A value of 1 indicates a reading taken before the sign was erected, a 2 indicates a reading taken shortly after erection of the sign and a 3 indicates a reading taken after the sign had been in place for some time.

`warning` A numeric column indicating whether the location of the reading was chosen to have a warning sign erected. A value of 1 indicates presence of a sign and a value of 2 indicates that no sign was erected.

`pair` A numeric column giving the pair number at which the reading was taken. Pairs were numbered from 1 to 14.

## Source

The data were kindly made available by Mr. Graham Amis, Cambridgeshire County Council, U.K.

aml

*Remission Times for Acute Myelogenous Leukaemia***Description**

The `aml` data frame has 23 rows and 3 columns.

A clinical trial to evaluate the efficacy of maintenance chemotherapy for acute myelogenous leukaemia was conducted by Embury et al. (1977) at Stanford University. After reaching a stage of remission through treatment by chemotherapy, patients were randomized into two groups. The first group received maintenance chemotherapy and the second group did not. The aim of the study was to see if maintenance chemotherapy increased the length of the remission. The data here formed a preliminary analysis which was conducted in October 1974.

**Usage**

```
aml
```

**Format**

This data frame contains the following columns:

`time` The length of the complete remission (in weeks).

`cens` An indicator of right censoring. 1 indicates that the patient had a relapse and so `time` is the length of the remission. 0 indicates that the patient had left the study or was still in remission in October 1974, that is the length of remission is right-censored.

`group` The group into which the patient was randomized. Group 1 received maintenance chemotherapy, group 2 did not.

**Note**

Package **survival** also has a dataset `aml`. It is the same data with different names and with `group` replaced by a factor `x`.

**Source**

The data were obtained from

Miller, R.G. (1981) *Survival Analysis*. John Wiley.

**References**

---

`beaver`*Beaver Body Temperature Data*

---

## Description

The `beaver` data frame has 100 rows and 4 columns. It is a multivariate time series of class `"ts"` and also inherits from class `"data.frame"`.

This data set is part of a long study into body temperature regulation in beavers. Four adult female beavers were live-trapped and had a temperature-sensitive radio transmitter surgically implanted. Readings were taken every 10 minutes. The location of the beaver was also recorded and her activity level was dichotomized by whether she was in the retreat or outside of it since high-intensity activities only occur outside of the retreat.

The data in this data frame are those readings for one of the beavers on a day in autumn.

## Usage

```
beaver
```

## Format

This data frame contains the following columns:

`day` The day number. The data includes only data from day 307 and early 308.

`time` The time of day formatted as hour-minute.

`temp` The body temperature in degrees Celsius.

`activ` The dichotomized activity indicator. 1 indicates that the beaver is outside of the retreat and therefore engaged in high-intensity activity.

## Source

The data were obtained from

Reynolds, P.S. (1994) Time-series analyses of beaver body temperatures. In *Case Studies in Biometry*. N. Lange, L. Ryan, L. Billard, D. Brillinger, L. Conquest and J. Greenhouse (editors), 211–228. John Wiley.

|---------|----------------------------------|
| bigcity | <i>Population of U.S. Cities</i> |
|---------|----------------------------------|

---

### Description

The `bigcity` data frame has 49 rows and 2 columns.

The `city` data frame has 10 rows and 2 columns.

The measurements are the population (in 1000's) of 49 U.S. cities in 1920 and 1930. The 49 cities are a random sample taken from the 196 largest cities in 1920. The `city` data frame consists of the first 10 observations in `bigcity`.

### Usage

```
bigcity
```

### Format

This data frame contains the following columns:

- u The 1920 population.
- x The 1930 population.

### Source

The data were obtained from

|      |                             |
|------|-----------------------------|
| boot | <i>Bootstrap Resampling</i> |
|------|-----------------------------|

---

### Description

Generate R bootstrap replicates of a statistic applied to data. Both parametric and nonparametric resampling are possible. For the nonparametric bootstrap, possible resampling methods are the ordinary bootstrap, the balanced bootstrap, antithetic resampling, and permutation. For nonparametric multi-sample problems stratified resampling is used: this is specified by including a vector of strata in the call to `boot`. Importance resampling weights may be specified.

### Usage

```
boot(data, statistic, R, sim = "ordinary", stype = c("i", "f", "w"),
      strata = rep(1,n), L = NULL, m = 0, weights = NULL,
      ran.gen = function(d, p) d, mle = NULL, simple = FALSE, ...,
      parallel = c("no", "multicore", "snow"),
      ncpus = getOption("boot.ncpus", 1L), cl = NULL)
```

**Arguments**

|                        |  |
|------------------------|--|
| <code>data</code>      | The data as a vector, matrix or data frame. If it is a matrix or data frame then each row is considered as one multivariate observation.   |
| <code>statistic</code> | A function which when applied to data returns a vector containing the statistic(s) of interest. When <code>sim = "parametric"</code> , the first argument to <code>statistic</code> must be the data. For each replicate a simulated dataset returned by <code>ran.gen</code> will be passed. In all other cases <code>statistic</code> must take at least two arguments. The first argument passed will always be the original data. The second will be a vector of indices, frequencies or weights which define the bootstrap sample. Further, if predictions are required, then a third argument is required which would be a vector of the random indices used to generate the bootstrap predictions. Any further arguments can be passed to <code>statistic</code> through the <code>...</code> argument. |
| <code>R</code>         | The number of bootstrap replicates. Usually this will be a single positive integer. For importance resampling, some resamples may use one set of weights and others use a different set of weights. In this case <code>R</code> would be a vector of integers where each component gives the number of resamples from each of the rows of weights.   |
| <code>sim</code>       | A character string indicating the type of simulation required. Possible values are "ordinary" (the default), "parametric", "balanced", "permutation", or "antithetic". Importance resampling is specified by including importance weights; the type of importance resampling must still be specified but may only be "ordinary" or "balanced" in this case.  |
| <code>stype</code>     | A character string indicating what the second argument of <code>statistic</code> represents. Possible values of <code>stype</code> are "i" (indices - the default), "f" (frequencies), or "w" (weights). Not used for <code>sim = "parametric"</code> .  |
| <code>strata</code>    | An integer vector or factor specifying the strata for multi-sample problems. This may be specified for any simulation, but is ignored when <code>sim = "parametric"</code> . When <code>strata</code> is supplied for a nonparametric bootstrap, the simulations are done within the specified strata.   |
| <code>L</code>         | Vector of influence values evaluated at the observations. This is used only when <code>sim</code> is "antithetic". If not supplied, they are calculated through a call to <code>empinf</code> . This will use the infinitesimal jackknife provided that <code>stype</code> is "w", otherwise the usual jackknife is used.  |
| <code>m</code>         | The number of predictions which are to be made at each bootstrap replicate. This is most useful for (generalized) linear models. This can only be used when <code>sim</code> is "ordinary". <code>m</code> will usually be a single integer but, if there are strata, it may be a vector with length equal to the number of strata, specifying how many of the errors for prediction should come from each strata. The actual predictions should be returned as the final part of the output of <code>statistic</code> , which should also take an argument giving the vector of indices of the errors to be used for the predictions.   |
| <code>weights</code>   | Vector or matrix of importance weights. If a vector then it should have as many elements as there are observations in <code>data</code> . When simulation from more than one set of weights is required, <code>weights</code> should be a matrix where each row of the matrix is one set of importance weights. If <code>weights</code> is a matrix then <code>R</code> must be a vector of length <code>nrow(weights)</code> . This parameter is ignored if <code>sim</code> is not "ordinary" or "balanced".   |
| <code>ran.gen</code>   | This function is used only when <code>sim = "parametric"</code> when it describes how random values are to be generated. It should be a function of two arguments.   |

|                       |  |
|-----------------------|--|
|                       | <p>The first argument should be the observed data and the second argument consists of any other information needed (e.g. parameter estimates). The second argument may be a list, allowing any number of items to be passed to <code>ran.gen</code>. The returned value should be a simulated data set of the same form as the observed data which will be passed to <code>statistic</code> to get a bootstrap replicate. It is important that the returned value be of the same shape and type as the original dataset. If <code>ran.gen</code> is not specified, the default is a function which returns the original data in which case all simulation should be included as part of <code>statistic</code>. Use of <code>sim = "parametric"</code> with a suitable <code>ran.gen</code> allows the user to implement any types of nonparametric resampling which are not supported directly.</p> |
| <code>mle</code>      | <p>The second argument to be passed to <code>ran.gen</code>. Typically these will be maximum likelihood estimates of the parameters. For efficiency <code>mle</code> is often a list containing all of the objects needed by <code>ran.gen</code> which can be calculated using the original data set only.</p>  |
| <code>simple</code>   | <p>logical, only allowed to be TRUE for <code>sim = "ordinary"</code>, <code>stype = "i"</code>, <code>n = 0</code> (otherwise ignored with a warning). By default a <code>n</code> by <code>R</code> index array is created: this can be large and if <code>simple = TRUE</code> this is avoided by sampling separately for each replication, which is slower but uses less memory.</p>   |
| <code>...</code>      | <p>Other named arguments for <code>statistic</code> which are passed unchanged each time it is called. Any such arguments to <code>statistic</code> should follow the arguments which <code>statistic</code> is required to have for the simulation. Beware of partial matching to arguments of <code>boot</code> listed above, and that arguments named <code>X</code> and <code>FUN</code> cause conflicts in some versions of <b>boot</b> (but not this one).</p>   |
| <code>parallel</code> | <p>The type of parallel operation to be used (if any). If missing, the default is taken from the option <code>"boot.parallel"</code> (and if that is not set, <code>"no"</code>).</p>  |
| <code>ncpus</code>    | <p>integer: number of processes to be used in parallel operation: typically one would chose this to the number of available CPUs.</p>  |
| <code>cl</code>       | <p>An optional <b>parallel</b> or <b>snow</b> cluster for use if <code>parallel = "snow"</code>. If not supplied, a cluster on the local machine is created for the duration of the <code>boot</code> call.</p>  |

## Details

The statistic to be bootstrapped can be as simple or complicated as desired as long as its arguments correspond to the dataset and (for a nonparametric bootstrap) a vector of indices, frequencies or weights. `statistic` is treated as a black box by the `boot` function and is not checked to ensure that these conditions are met.

The first order balanced bootstrap is described in Davison, Hinkley and Schechtman (1986). The antithetic bootstrap is described by Hall (1989) and is experimental, particularly when used with `strata`. The other non-parametric simulation types are the ordinary bootstrap (possibly with unequal probabilities), and permutation which returns random permutations of cases. All of these methods work independently within `strata` if that argument is supplied.

For the parametric bootstrap it is necessary for the user to specify how the resampling is to be conducted. The best way of accomplishing this is to specify the function `ran.gen` which will return a simulated data set from the observed data set and a set of parameter estimates specified in `mle`.

## Value

The returned value is an object of class `"boot"`, containing the following components:

|                        |  |
|------------------------|--|
| <code>t0</code>        | The observed value of <code>statistic</code> applied to data.  |
| <code>t</code>         | A matrix with <code>sum(R)</code> rows each of which is a bootstrap replicate of the result of calling <code>statistic</code> .  |
| <code>R</code>         | The value of <code>R</code> as passed to <code>boot</code> .   |
| <code>data</code>      | The data as passed to <code>boot</code> .  |
| <code>seed</code>      | The value of <code>.Random.seed</code> when <code>boot</code> started work.  |
| <code>statistic</code> | The function <code>statistic</code> as passed to <code>boot</code> .   |
| <code>sim</code>       | Simulation type used.  |
| <code>stype</code>     | Statistic type as passed to <code>boot</code> .  |
| <code>call</code>      | The original call to <code>boot</code> .   |
| <code>strata</code>    | The strata used. This is the vector passed to <code>boot</code> , if it was supplied or a vector of ones if there were no strata. It is not returned if <code>sim</code> is "parametric".  |
| <code>weights</code>   | The importance sampling weights as passed to <code>boot</code> or the empirical distribution function weights if no importance sampling weights were specified. It is omitted if <code>sim</code> is not one of "ordinary" or "balanced".  |
| <code>pred.i</code>    | If predictions are required ( <code>m &gt; 0</code> ) this is the matrix of indices at which predictions were calculated as they were passed to <code>statistic</code> . Omitted if <code>m</code> is 0 or <code>sim</code> is not "ordinary".   |
| <code>L</code>         | The influence values used when <code>sim</code> is "antithetic". If no such values were specified and <code>stype</code> is not "w" then <code>L</code> is returned as consecutive integers corresponding to the assumption that data is ordered by influence values. This component is omitted when <code>sim</code> is not "antithetic". |
| <code>ran.gen</code>   | The random generator function used if <code>sim</code> is "parametric". This component is omitted for any other value of <code>sim</code> .  |
| <code>mle</code>       | The parameter estimates passed to <code>boot</code> when <code>sim</code> is "parametric". It is omitted for all other values of <code>sim</code> .  |

There are `c`, `plot` and `print` methods for this class.

### Parallel operation

When `parallel = "multicore"` is used (not available on Windows), each worker process inherits the environment of the current session, including the workspace and the loaded namespaces and attached packages (but not the random number seed: see below).

More work is needed when `parallel = "snow"` is used: the worker processes are newly created R processes, and `statistic` needs to arrange to set up the environment it needs: often a good way to do that is to make use of lexical scoping since when `statistic` is sent to the worker processes its enclosing environment is also sent. (E.g. see the example for `jack.after.boot` where ancillary functions are nested inside the `statistic` function.) `parallel = "snow"` is primarily intended to be used on multi-core Windows machine where `parallel = "multicore"` is not available.

For most of the `boot` methods the resampling is done in the master process, but not if `simple = TRUE` nor `sim = "parametric"`. In those cases (or where `statistic` itself uses random numbers), more care is needed if the results need to be reproducible. Resampling is done in the worker processes by `censboot` (`sim = "wierd"`) and by most of the schemes in `tsboot` (the exceptions being `sim == "fixed"` and `sim == "geom"` with the default `ran.gen`).

Where random-number generation is done in the worker processes, the default behaviour is that each worker chooses a separate seed, non-reproducibly. However, with `parallel =`

"multicore" or `parallel = "snow"` using the default cluster, a second approach is used if `RNGkind("L'Ecuyer-CMRG")` has been selected. In that approach each worker gets a different subsequence of the RNG stream based on the seed at the time the worker is spawned and so the results will be reproducible if `ncpus` is unchanged, and for `parallel = "multicore"` if `parallel::mc.reset.stream()` is called: see the examples for `mclapply`.

Note that loading the **parallel** namespace may change the random seed, so for maximum reproducibility this should be done before calling this function.

  m2 <- sum(d[-gp1,1] * f[-gp1])/sum(f[-gp1])
  ss1 <- sum(d[gp1,1]^2 * f[gp1]) - (m1 * m1 * sum(f[gp1]))
  ss2 <- sum(d[-gp1,1]^2 * f[-gp1]) - (m2 * m2 * sum(f[-gp1]))
}
```

```

      c(m1 - m2, (ss1 + ss2)/(sum(f) - 2))
    }
    grav1 <- gravity[as.numeric(gravity[,2]) >= 7,]
    boot(grav1, diff.means, R = 999, stype = "f", strata = grav1[,2])

# In this example we show the use of boot in a prediction from
# regression based on the nuclear data. This example is taken
# from Example 6.8 of Davison and Hinkley (1997). Notice also
# that two extra arguments to 'statistic' are passed through boot.
nuke <- nuclear[, c(1, 2, 5, 7, 8, 10, 11)]
nuke.lm <- glm(log(cost) ~ date+log(cap)+ne+ct+log(cum.n)+pt, data = nuke)
nuke.diag <- glm.diag(nuke.lm)
nuke.res <- nuke.diag$res * nuke.diag$sd
nuke.res <- nuke.res - mean(nuke.res)

# We set up a new data frame with the data, the standardized
# residuals and the fitted values for use in the bootstrap.
nuke.data <- data.frame(nuke, resid = nuke.res, fit = fitted(nuke.lm))

# Now we want a prediction of plant number 32 but at date 73.00
new.data <- data.frame(cost = 1, date = 73.00, cap = 886, ne = 0,
                      ct = 0, cum.n = 11, pt = 1)
new.fit <- predict(nuke.lm, new.data)

nuke.fun <- function(dat, inds, i.pred, fit.pred, x.pred)
{
  lm.b <- glm(fit+resid[inds] ~ date+log(cap)+ne+ct+log(cum.n)+pt,
             data = dat)
  pred.b <- predict(lm.b, x.pred)
  c(coef(lm.b), pred.b - (fit.pred + dat$resid[i.pred]))
}

nuke.boot <- boot(nuke.data, nuke.fun, R = 999, m = 1,
                 fit.pred = new.fit, x.pred = new.data)
# The bootstrap prediction squared error would then be found by
mean(nuke.boot$t[, 8]^2)
# Basic bootstrap prediction limits would be
new.fit - sort(nuke.boot$t[, 8])[c(975, 25)]

# Finally a parametric bootstrap. For this example we shall look
# at the air-conditioning data. In this example our aim is to test
# the hypothesis that the true value of the index is 1 (i.e. that
# the data come from an exponential distribution) against the
# alternative that the data come from a gamma distribution with
# index not equal to 1.
air.fun <- function(data) {
  ybar <- mean(data$hours)
  para <- c(log(ybar), mean(log(data$hours)))
  ll <- function(k) {
    if (k <= 0) 1e200 else lgamma(k)-k*(log(k)-1-para[1]+para[2])
  }
  khat <- nlm(ll, ybar^2/var(data$hours))$estimate
  c(ybar, khat)
}

air.rg <- function(data, mle) {

```

```

# Function to generate random exponential variates.
# mle will contain the mean of the original data
out <- data
out$hours <- rexp(nrow(out), 1/mle)
out
}

air.boot <- boot(aircondit, air.fun, R = 999, sim = "parametric",
               ran.gen = air.rg, mle = mean(aircondit$hours))

# The bootstrap p-value can then be approximated by
sum(abs(air.boot$t[,2]-1) > abs(air.boot$t0[2]-1))/(1+air.boot$R)

```

---

|            |                                    |
|------------|------------------------------------|
| boot.array | <i>Bootstrap Resampling Arrays</i> |
|------------|------------------------------------|

---

## Description

This function takes a bootstrap object calculated by one of the functions `boot`, `censboot`, or `tilt.boot` and returns the frequency (or index) array for the bootstrap resamples.

## Usage

```
boot.array(boot.out, indices)
```

## Arguments

|                       |   |
|-----------------------|---|
| <code>boot.out</code> | An object of class "boot" returned by one of the generation functions for such an object.   |
| <code>indices</code>  | A logical argument which specifies whether to return the frequency array or the raw index array. The default is <code>indices=FALSE</code> unless <code>boot.out</code> was created by <code>tsboot</code> in which case the default is <code>indices=TRUE</code> . |

## Details

The process by which the original index array was generated is repeated with the same value of `.Random.seed`. If the frequency array is required then `freq.array` is called to convert the index array to a frequency array.

A resampling array can only be returned when such a concept makes sense. In particular it cannot be found for any parametric or model-based resampling schemes. Hence for objects generated by `censboot` the only resampling scheme for which such an array can be found is ordinary case resampling. Similarly if `boot.out$sim` is "parametric" in the case of `boot` or "model" in the case of `tsboot` the array cannot be found. Note also that for post-blackened bootstraps from `tsboot` the indices found will relate to those prior to any post-blackening and so will not be useful.

Frequency arrays are used in many post-bootstrap calculations such as the jackknife-after-bootstrap and finding importance sampling weights. They are also used to find empirical influence values through the regression method.

**Value**

A matrix with `boot.out$R` rows and `n` columns where `n` is the number of observations in `boot.out$data`. If `indices` is `FALSE` then this will give the frequency of each of the original observations in each bootstrap resample. If `indices` is `TRUE` it will give the indices of the bootstrap resamples in the order in which they would have been passed to the statistic.

**Side Effects**

This function temporarily resets `.Random.seed` to the value in `boot.out$seed` and then returns it to its original value at the end of the function.

**See Also**

`boot`, `censboot`, `freq.array`, `tilt.boot`, `tsboot`

**Examples**

```
# A frequency array for a nonparametric bootstrap
city.boot <- boot(city, corr, R = 40, stype = "w")
boot.array(city.boot)

perm.cor <- function(d,i) cor(d$x,d$u[i])
city.perm <- boot(city, perm.cor, R = 40, sim = "permutation")
boot.array(city.perm, indices = TRUE)
```

---

`boot.ci`

*Nonparametric Bootstrap Confidence Intervals*

---

**Description**

This function generates 5 different types of equi-tailed two-sided nonparametric confidence intervals. These are the first order normal approximation, the basic bootstrap interval, the studentized bootstrap interval, the bootstrap percentile interval, and the adjusted bootstrap percentile (BCa) interval. All or a subset of these intervals can be generated.

**Usage**

```
boot.ci(boot.out, conf = 0.95, type = "all",
        index = 1:min(2,length(boot.out$t0)), var.t0 = NULL,
        var.t = NULL, t0 = NULL, t = NULL, L = NULL,
        h = function(t) t, hdot = function(t) rep(1,length(t)),
        hinv = function(t) t, ...)
```

**Arguments**

|                       |   |
|-----------------------|---|
| <code>boot.out</code> | An object of class "boot" containing the output of a bootstrap calculation.   |
| <code>conf</code>     | A scalar or vector containing the confidence level(s) of the required interval(s).  |
| <code>type</code>     | A vector of character strings representing the type of intervals required. The value should be any subset of the values <code>c("norm", "basic", "stud", "perc", "bca")</code> or simply <code>"all"</code> which will compute all five types of intervals. |

|                     |  |
|---------------------|--|
| <code>index</code>  | This should be a vector of length 1 or 2. The first element of <code>index</code> indicates the position of the variable of interest in <code>boot.out\$t0</code> and the relevant column in <code>boot.out\$t</code> . The second element indicates the position of the variance of the variable of interest. If both <code>var.t0</code> and <code>var.t</code> are supplied then the second element of <code>index</code> (if present) is ignored. The default is that the variable of interest is in position 1 and its variance is in position 2 (as long as there are 2 positions in <code>boot.out\$t0</code> ).                          |
| <code>var.t0</code> | If supplied, a value to be used as an estimate of the variance of the statistic for the normal approximation and studentized intervals. If it is not supplied and <code>length(index)</code> is 2 then <code>var.t0</code> defaults to <code>boot.out\$t0[index[2]]</code> otherwise <code>var.t0</code> is undefined. For studentized intervals <code>var.t0</code> must be defined. For the normal approximation, if <code>var.t0</code> is undefined it defaults to <code>var(t)</code> . If a transformation is supplied through the argument <code>h</code> then <code>var.t0</code> should be the variance of the untransformed statistic. |
| <code>var.t</code>  | This is a vector (of length <code>boot.out\$R</code> ) of variances of the bootstrap replicates of the variable of interest. It is used only for studentized intervals. If it is not supplied and <code>length(index)</code> is 2 then <code>var.t</code> defaults to <code>boot.out\$t[,index[2]]</code> , otherwise its value is undefined which will cause an error for studentized intervals. If a transformation is supplied through the argument <code>h</code> then <code>var.t</code> should be the variance of the untransformed bootstrap statistics.  |
| <code>t0</code>     | The observed value of the statistic of interest. The default value is <code>boot.out\$t0[index[1]]</code> . Specification of <code>t0</code> and <code>t</code> allows the user to get intervals for a transformed statistic which may not be in the bootstrap output object. See the second example below. An alternative way of achieving this would be to supply the functions <code>h</code> , <code>hdot</code> , and <code>hinv</code> below.  |
| <code>t</code>      | The bootstrap replicates of the statistic of interest. It must be a vector of length <code>boot.out\$R</code> . It is an error to supply one of <code>t0</code> or <code>t</code> but not the other. Also if studentized intervals are required and <code>t0</code> and <code>t</code> are supplied then so should be <code>var.t0</code> and <code>var.t</code> . The default value is <code>boot.out\$t[,index]</code> .   |
| <code>L</code>      | The empirical influence values of the statistic of interest for the observed data. These are used only for BCa intervals. If a transformation is supplied through the parameter <code>h</code> then <code>L</code> should be the influence values for <code>t</code> ; the values for <code>h(t)</code> are derived from these and <code>hdot</code> within the function. If <code>L</code> is not supplied then the values are calculated using <code>empinf</code> if they are needed.   |
| <code>h</code>      | A function defining a transformation. The intervals are calculated on the scale of <code>h(t)</code> and the inverse function <code>hinv</code> applied to the resulting intervals. It must be a function of one variable only and for a vector argument, it must return a vector of the same length, i.e. <code>h(c(t1,t2,t3))</code> should return <code>c(h(t1),h(t2),h(t3))</code> . The default is the identity function.   |
| <code>hdot</code>   | A function of one argument returning the derivative of <code>h</code> . It is a required argument if <code>h</code> is supplied and normal, studentized or BCa intervals are required. The function is used for approximating the variances of <code>h(t0)</code> and <code>h(t)</code> using the delta method, and also for finding the empirical influence values for BCa intervals. Like <code>h</code> it should be able to take a vector argument and return a vector of the same length. The default is the constant function 1.   |
| <code>hinv</code>   | A function, like <code>h</code> , which returns the inverse of <code>h</code> . It is used to transform the intervals calculated on the scale of <code>h(t)</code> back to the original scale. The default is the identity function. If <code>h</code> is supplied but <code>hinv</code> is not, then the intervals returned will be on the transformed scale.   |

... Any extra arguments that `boot.out$statistic` is expecting. These arguments are needed only if BCa intervals are required and `L` is not supplied since in that case `L` is calculated through a call to `empinf` which calls `boot.out$statistic`.

## Details

The formulae on which the calculations are based can be found in Chapter 5 of Davison and Hinkley (1997). Function `boot` must be run prior to running this function to create the object to be passed as `boot.out`.

Variance estimates are required for studentized intervals. The variance of the observed statistic is optional for normal theory intervals. If it is not supplied then the bootstrap estimate of variance is used. The normal intervals also use the bootstrap bias correction.

Interpolation on the normal quantile scale is used when a non-integer order statistic is required. If the order statistic used is the smallest or largest of the `R` values in `boot.out` a warning is generated and such intervals should not be considered reliable.

## Value

An object of type `"bootci"` which contains the intervals. It has components

|                      |  |
|----------------------|--|
| <code>R</code>       | The number of bootstrap replicates on which the intervals were based.  |
| <code>t0</code>      | The observed value of the statistic on the same scale as the intervals.  |
| <code>call</code>    | The call to <code>boot.ci</code> which generated the object.<br>It will also contain one or more of the following components depending on the value of <code>type</code> used in the call to <code>bootci</code> .   |
| <code>normal</code>  | A matrix of intervals calculated using the normal approximation. It will have 3 columns, the first being the level and the other two being the upper and lower endpoints of the intervals.   |
| <code>basic</code>   | The intervals calculated using the basic bootstrap method.   |
| <code>student</code> | The intervals calculated using the studentized bootstrap method.   |
| <code>percent</code> | The intervals calculated using the bootstrap percentile method.  |
| <code>bca</code>     | The intervals calculated using the adjusted bootstrap percentile (BCa) method.<br>These latter four components will be matrices with 5 columns, the first column containing the level, the next two containing the indices of the order statistics used in the calculations and the final two the calculated endpoints themselves. |

```

**Description**

The `brambles` data frame has 823 rows and 3 columns.

The location of living bramble canes in a 9m square plot was recorded. We take 9m to be the unit of distance so that the plot can be thought of as a unit square. The bramble canes were also classified by their age.

**Usage**

```
brambles
```

**Format**

This data frame contains the following columns:

`x` The x coordinate of the position of the cane in the plot.

`y` The y coordinate of the position of the cane in the plot.

`age` The age classification of the canes; 0 indicates a newly emerged cane, 1 indicates a one year old cane and 2 indicates a two year old cane.

`breslow`*Smoking Deaths Among Doctors*

---

**Description**

The `breslow` data frame has 10 rows and 5 columns.

In 1961 Doll and Hill sent out a questionnaire to all men on the British Medical Register enquiring about their smoking habits. Almost 70% of such men replied. Death certificates were obtained for medical practitioners and causes of death were assigned on the basis of these certificates. The `breslow` data set contains the person-years of observations and deaths from coronary artery disease accumulated during the first ten years of the study.

**Usage**

```
breslow
```

**Format**

This data frame contains the following columns:

- age The mid-point of the 10 year age-group for the doctors.
- smoke An indicator of whether the doctors smoked (1) or not (0).
- n The number of person-years in the category.
- y The number of deaths attributed to coronary artery disease.
- ns The number of smoker years in the category (`smoke*n`).

**Source**

The data were obtained from

Breslow, N.E. (1985) Cohort Analysis in Epidemiology. In *A Celebration of Statistics* A.C. Atkinson and S.E. Fienberg (editors), 109–143. Springer-Verlag.

calcium

*Calcium Uptake Data*

---

**Description**

The `calcium` data frame has 27 rows and 2 columns.

Howard Grimes from the Botany Department, North Carolina State University, conducted an experiment for biochemical analysis of intracellular storage and transport of calcium across plasma membrane. Cells were suspended in a solution of radioactive calcium for a certain length of time and then the amount of radioactive calcium that was absorbed by the cells was measured. The experiment was repeated independently with 9 different times of suspension each replicated 3 times.

**Usage**

`calcium`

**Format**

This data frame contains the following columns:

- time The time (in minutes) that the cells were suspended in the solution.
- cal The amount of calcium uptake (nmoles/mg).

**Source**

The data were obtained from

Rawlings, J.O. (1988) *Applied Regression Analysis*. Wadsworth and Brooks/Cole Statistics/Probability Series.

|------|--------------------------------|
| cane | <i>Sugar-cane Disease Data</i> |
|------|--------------------------------|

---

## Description

The `cane` data frame has 180 rows and 5 columns. The data frame represents a randomized block design with 45 varieties of sugar-cane and 4 blocks.

## Usage

```
cane
```

## Format

This data frame contains the following columns:

- `n` The total number of shoots in each plot.
- `r` The number of diseased shoots.
- `x` The number of pieces of the stems, out of 50, planted in each plot.
- `var` A factor indicating the variety of sugar-cane in each plot.
- `block` A factor for the blocks.

## Details

The aim of the experiment was to classify the varieties into resistant, intermediate and susceptible to a disease called "coal of sugar-cane" (carvão da cana-de-açúcar). This is a disease that is common in sugar-cane plantations in certain areas of Brazil.

For each plot, fifty pieces of sugar-cane stem were put in a solution containing the disease agent and then some were planted in the plot. After a fixed period of time, the total number of shoots and the number of diseased shoots were recorded.

## Source

The data were kindly supplied by Dr. C.G.B. Demetrio of Escola Superior de Agricultura, Universidade de São Paulo, Brazil.

cd4

*CD4 Counts for HIV-Positive Patients***Description**

The `cd4` data frame has 20 rows and 2 columns.

CD4 cells are carried in the blood as part of the human immune system. One of the effects of the HIV virus is that these cells die. The count of CD4 cells is used in determining the onset of full-blown AIDS in a patient. In this study of the effectiveness of a new anti-viral drug on HIV, 20 HIV-positive patients had their CD4 counts recorded and then were put on a course of treatment with this drug. After using the drug for one year, their CD4 counts were again recorded. The aim of the experiment was to show that patients taking the drug had increased CD4 counts which is not generally seen in HIV-positive patients.

**Usage**

```
cd4
```

**Format**

This data frame contains the following columns:

`baseline` The CD4 counts (in 100's) on admission to the trial.

`oneyear` The CD4 counts (in 100's) after one year of treatment with the new drug.

**Source**

The data were obtained from

DiCiccio, T.J. and Efron B. (1996) Bootstrap confidence intervals (with Discussion). *Statistical Science*, **11**, 189–228.

cd4.nested

*Nested Bootstrap of cd4 data***Description**

This is an example of a nested bootstrap for the correlation coefficient of the `cd4` data frame. It is used in a practical in Chapter 5 of Davison and Hinkley (1997).

**References**

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

**See Also**

[cd4](#)

**Description**

This function applies types of bootstrap resampling which have been suggested to deal with right-censored data. It can also do model-based resampling using a Cox regression model.

**Usage**

```
censboot(data, statistic, R, F.surv, G.surv, strata = matrix(1,n,2),
  sim = "ordinary", cox = NULL, index = c(1, 2), ...,
  parallel = c("no", "multicore", "snow"),
  ncpus = getOption("boot.ncpus", 1L), cl = NULL)
```

**Arguments**

|                        |   |
|------------------------|---|
| <code>data</code>      | The data frame or matrix containing the data. It must have at least two columns, one of which contains the times and the other the censoring indicators. It is allowed to have as many other columns as desired (although efficiency is reduced for large numbers of columns) except for <code>sim = "weird"</code> when it should only have two columns - the times and censoring indicators. The columns of <code>data</code> referenced by the components of <code>index</code> are taken to be the times and censoring indicators.  |
| <code>statistic</code> | A function which operates on the data frame and returns the required statistic. Its first argument must be the data. Any other arguments that it requires can be passed using the <code>...</code> argument. In the case of <code>sim = "weird"</code> , the data passed to <code>statistic</code> only contains the times and censoring indicator regardless of the actual number of columns in <code>data</code> . In all other cases the data passed to <code>statistic</code> will be of the same form as the original data. When <code>sim = "weird"</code> , the actual number of observations in the resampled data sets may not be the same as the number in <code>data</code> . For this reason, if <code>sim = "weird"</code> and <code>strata</code> is supplied, <code>statistic</code> should also take a numeric vector indicating the strata. This allows the statistic to depend on the strata if required. |
| <code>R</code>         | The number of bootstrap replicates.   |
| <code>F.surv</code>    | An object returned from a call to <code>survfit</code> giving the survivor function for the data. This is a required argument unless <code>sim = "ordinary"</code> or <code>sim = "model"</code> and <code>cox</code> is missing.   |
| <code>G.surv</code>    | Another object returned from a call to <code>survfit</code> but with the censoring indicators reversed to give the product-limit estimate of the censoring distribution. Note that for consistency the uncensored times should be reduced by a small amount in the call to <code>survfit</code> . This is a required argument whenever <code>sim = "cond"</code> or when <code>sim = "model"</code> and <code>cox</code> is supplied.   |
| <code>strata</code>    | The strata used in the calls to <code>survfit</code> . It can be a vector or a matrix with 2 columns. If it is a vector then it is assumed to be the strata for the survival distribution, and the censoring distribution is assumed to be the same for all observations. If it is a matrix then the first column is the strata for the survival distribution and the second is the strata for the censoring distribution. When <code>sim = "weird"</code> only the strata for the survival distribution are used since the   |

|                                  |  |
|----------------------------------|--|
|                                  | censoring times are considered fixed. When <code>sim = "ordinary"</code> , only one set of strata is used to stratify the observations, this is taken to be the first column of <code>strata</code> when it is a matrix.   |
| <code>sim</code>                 | The simulation type. Possible types are <code>"ordinary"</code> (case resampling), <code>"model"</code> (equivalent to <code>"ordinary"</code> if <code>cox</code> is missing, otherwise it is model-based resampling), <code>"weird"</code> (the weird bootstrap - this cannot be used if <code>cox</code> is supplied), and <code>"cond"</code> (the conditional bootstrap, in which censoring times are resampled from the conditional censoring distribution). |
| <code>cox</code>                 | An object returned from <code>coxph</code> . If it is supplied, then <code>F.surv</code> should have been generated by a call of the form <code>survfit(cox)</code> .  |
| <code>index</code>               | A vector of length two giving the positions of the columns in <code>data</code> which correspond to the times and censoring indicators respectively.   |
| <code>...</code>                 | Other named arguments which are passed unchanged to <code>statistic</code> each time it is called. Any such arguments to <code>statistic</code> must follow the arguments which <code>statistic</code> is required to have for the simulation. Beware of partial matching to arguments of <code>censboot</code> listed above, and that arguments named <code>X</code> and <code>FUN</code> cause conflicts in some versions of <b>boot</b> (but not this one).     |
| <code>parallel, ncpus, cl</code> | See the help for <code>boot</code> .   |

## Details

The various types of resampling are described in Davison and Hinkley (1997) in sections 3.5 and 7.3. The simplest is case resampling which simply resamples with replacement from the observations.

The conditional bootstrap simulates failure times from the estimate of the survival distribution. Then, for each observation its simulated censoring time is equal to the observed censoring time if the observation was censored and generated from the estimated censoring distribution conditional on being greater than the observed failure time if the observation was uncensored. If the largest value is censored then it is given a nominal failure time of `Inf` and conversely if it is uncensored it is given a nominal censoring time of `Inf`. This is necessary to allow the largest observation to be in the resamples.

If a Cox regression model is fitted to the data and supplied, then the failure times are generated from the survival distribution using that model. In this case the censoring times can either be simulated from the estimated censoring distribution (`sim = "model"`) or from the conditional censoring distribution as in the previous paragraph (`sim = "cond"`).

The weird bootstrap holds the censored observations as fixed and also the observed failure times. It then generates the number of events at each failure time using a binomial distribution with mean 1 and denominator the number of failures that could have occurred at that time in the original data set. In our implementation we insist that there is a least one simulated event in each stratum for every bootstrap dataset.

When there are strata involved and `sim` is either `"model"` or `"cond"` the situation becomes more difficult. Since the strata for the survival and censoring distributions are not the same it is possible that for some observations both the simulated failure time and the simulated censoring time are infinite. To see this consider an observation in stratum 1F for the survival distribution and stratum 1G for the censoring distribution. Now if the largest value in stratum 1F is censored it is given a nominal failure time of `Inf`, also if the largest value in stratum 1G is uncensored it is given a nominal censoring time of `Inf` and so both the simulated failure and censoring times could be infinite. When this happens the simulated value is considered to be a failure at the time of the largest observed failure time in the stratum for the survival distribution.

When `parallel = "snow"` and `cl` is not supplied, `library(survival)` is run in each of the worker processes.

## Value

An object of class `"boot"` containing the following components:

|                        |   |
|------------------------|---|
| <code>t0</code>        | The value of <code>statistic</code> when applied to the original data.  |
| <code>t</code>         | A matrix of bootstrap replicates of the values of <code>statistic</code> .  |
| <code>R</code>         | The number of bootstrap replicates performed.   |
| <code>sim</code>       | The simulation type used. This will usually be the input value of <code>sim</code> unless that was <code>"model"</code> but <code>cox</code> was not supplied, in which case it will be <code>"ordinary"</code> .   |
| <code>data</code>      | The data used for the bootstrap. This will generally be the input value of <code>data</code> unless <code>sim = "weird"</code> , in which case it will just be the columns containing the times and the censoring indicators.   |
| <code>seed</code>      | The value of <code>.Random.seed</code> when <code>censboot</code> started work.   |
| <code>statistic</code> | The input value of <code>statistic</code> .   |
| <code>strata</code>    | The strata used in the resampling. When <code>sim = "ordinary"</code> this will be a vector which stratifies the observations, when <code>sim = "weird"</code> it is the strata for the survival distribution and in all other cases it is a matrix containing the strata for the survival distribution and the censoring distribution. |
| <code>call</code>      | The original call to <code>censboot</code> .  |

channing

---

*Channing House Data*

---

## Description

The channing data frame has 462 rows and 5 columns.

Channing House is a retirement centre in Palo Alto, California. These data were collected between the opening of the house in 1964 until July 1, 1975. In that time 97 men and 365 women passed through the centre. For each of these, their age on entry and also on leaving or death was recorded. A large number of the observations were censored mainly due to the resident being alive on July 1, 1975 when the data was collected. Over the time of the study 130 women and 46 men died at Channing House. Differences between the survival of the sexes, taking age into account, was one of the primary concerns of this study.

## Usage

```
channing
```

**Format**

This data frame contains the following columns:

- `sex` A factor for the sex of each resident ("Male" or "Female").
- `entry` The residents age (in months) on entry to the centre
- `exit` The age (in months) of the resident on death, leaving the centre or July 1, 1975 whichever event occurred first.
- `time` The length of time (in months) that the resident spent at Channing House.  
(`time=exit-entry`)
- `cens` The indicator of right censoring. 1 indicates that the resident died at Channing House, 0 indicates that they left the house prior to July 1, 1975 or that they were still alive and living in the centre at that date.

claridge

*Genetic Links to Left-handedness*

---

**Description**

The `claridge` data frame has 37 rows and 2 columns.

The data are from an experiment which was designed to look for a relationship between a certain genetic characteristic and handedness. The 37 subjects were women who had a son with mental retardation due to inheriting a defective X-chromosome. For each such mother a genetic measurement of their DNA was made. Larger values of this measurement are known to be linked to the defective gene and it was hypothesized that larger values might also be linked to a progressive shift away from right-handedness. Each woman also filled in a questionnaire regarding which hand they used for various tasks. From these questionnaires a measure of hand preference was found for each mother. The scale of this measure goes from 1, indicating someone who always favours their right hand, to 8, indicating someone who always favours their left hand. Between these two extremes are people who favour one hand for some tasks and the other for other tasks.

**Usage**

```
claridge
```

**Format**

This data frame contains the following columns:

- `dnan` The genetic measurement on each woman's DNA.
- `hand` The measure of left-handedness on an integer scale from 1 to 8.

**Source**

The data were kindly made available by Dr. Gordon S. Claridge from the Department of Experimental Psychology, University of Oxford.

`co.transfer`
*Carbon Monoxide Transfer*

---

### Description

The `co.transfer` data frame has 7 rows and 2 columns. Seven smokers with chickenpox had their levels of carbon monoxide transfer measured on entry to hospital and then again after 1 week. The main question being whether one week of hospitalization has changed the carbon monoxide transfer factor.

### Usage

```
co.transfer
```

### Format

This data frame contains the following columns:

`entry` Carbon monoxide transfer factor on entry to hospital.

`week` Carbon monoxide transfer one week after admittance to hospital.

### Source

The data were obtained from

Hand, D.J., Daly, F., Lunn, A.D., McConway, K.J. and Ostrowski, E (1994) *A Handbook of Small Data Sets*. Chapman and Hall.

---

`coal`
*Dates of Coal Mining Disasters*

---

### Description

The `coal` data frame has 191 rows and 1 columns.

This data frame gives the dates of 191 explosions in coal mines which resulted in 10 or more fatalities. The time span of the data is from March 15, 1851 until March 22 1962.

### Usage

```
coal
```

**Format**

This data frame contains the following column:

`date` The date of the disaster. The integer part of `date` gives the year. The day is represented as the fraction of the year that had elapsed on that day.

**Source**

The data were obtained from

Hand, D.J., Daly, F., Lunn, A.D., McConway, K.J. and Ostrowski, E. (1994) *A Handbook of Small Data Sets*, Chapman and Hall.

---

|         |                                     |
|---------|-------------------------------------|
| control | <i>Control Variate Calculations</i> |
|---------|-------------------------------------|

---

**Description**

This function will find control variate estimates from a bootstrap output object. It can either find the adjusted bias estimate using post-simulation balancing or it can estimate the bias, variance, third cumulant and quantiles, using the linear approximation as a control variate.

**Usage**

```
control(boot.out, L = NULL, distn = NULL, index = 1, t0 = NULL,
        t = NULL, bias.adj = FALSE, alpha = NULL, ...)
```

**Arguments**

|                       |   |
|-----------------------|---|
| <code>boot.out</code> | A bootstrap output object returned from <code>boot</code> . The bootstrap replicates must have been generated using the usual nonparametric bootstrap.  |
| <code>L</code>        | The empirical influence values for the statistic of interest. If <code>L</code> is not supplied then <code>empinf</code> is called to calculate them from <code>boot.out</code> .   |
| <code>distn</code>    | If present this must be the output from <code>smooth.spline</code> giving the distribution function of the linear approximation. This is used only if <code>bias.adj</code> is <code>FALSE</code> . Normally this would be found using a saddlepoint approximation. If it is not supplied in that case then it is calculated by <code>saddle.distn</code> . |
| <code>index</code>    | The index of the variable of interest in the output of <code>boot.out\$statistic</code> .   |
| <code>t0</code>       | The observed value of the statistic of interest on the original data set <code>boot.out\$data</code> . This argument is used only if <code>bias.adj</code> is <code>FALSE</code> . The input value is ignored if <code>t</code> is not also supplied. The default value is <code>boot.out\$t0[index]</code> .   |
| <code>t</code>        | The bootstrap replicate values of the statistic of interest. This argument is used only if <code>bias.adj</code> is <code>FALSE</code> . The input is ignored if <code>t0</code> is not supplied also. The default value is <code>boot.out\$t[, index]</code> .   |

|                       |  |
|-----------------------|--|
| <code>bias.adj</code> | A logical variable which if <code>TRUE</code> specifies that the adjusted bias estimate using post-simulation balance is all that is required. If <code>bias.adj</code> is <code>FALSE</code> (default) then the linear approximation to the statistic is calculated and used as a control variate in estimates of the bias, variance and third cumulant as well as quantiles.       |
| <code>alpha</code>    | The alpha levels for the required quantiles if <code>bias.adj</code> is <code>FALSE</code> .   |
| <code>...</code>      | Any additional arguments that <code>boot.out\$statistic</code> requires. These are passed unchanged every time <code>boot.out\$statistic</code> is called. <code>boot.out\$statistic</code> is called once if <code>bias.adj</code> is <code>TRUE</code> , otherwise it may be called by <code>empinf</code> for empirical influence calculations if <code>L</code> is not supplied. |

### Details

If `bias.adj` is `FALSE` then the linear approximation to the statistic is found and evaluated at each bootstrap replicate. Then using the equation  $T^* = Tl^* + (T^* - Tl^*)$ , moment estimates can be found. For quantile estimation the distribution of the linear approximation to  $t$  is approximated very accurately by saddlepoint methods, this is then combined with the bootstrap replicates to approximate the bootstrap distribution of  $t$  and hence to estimate the bootstrap quantiles of  $t$ .

### Value

If `bias.adj` is `TRUE` then the returned value is the adjusted bias estimate.

If `bias.adj` is `FALSE` then the returned value is a list with the following components

|                        |   |
|------------------------|---|
| <code>L</code>         | The empirical influence values used. These are the input values if supplied, and otherwise they are the values calculated by <code>empinf</code> .  |
| <code>tL</code>        | The linear approximations to the bootstrap replicates $t$ of the statistic of interest.   |
| <code>bias</code>      | The control estimate of bias using the linear approximation to $t$ as a control variate.  |
| <code>var</code>       | The control estimate of variance using the linear approximation to $t$ as a control variate.  |
| <code>k3</code>        | The control estimate of the third cumulant using the linear approximation to $t$ as a control variate.  |
| <code>quantiles</code> | A matrix with two columns; the first column are the alpha levels used for the quantiles and the second column gives the corresponding control estimates of the quantiles using the linear approximation to $t$ as a control variate.  |
| <code>distn</code>     | An output object from <code>smooth.spline</code> describing the saddlepoint approximation to the bootstrap distribution of the linear approximation to $t$ . If <code>distn</code> was supplied on input then this is the same as the input otherwise it is calculated by a call to <code>saddle.distn</code> . |

**Examples**

```
# Use of control variates for the variance of the air-conditioning data
mean.fun <- function(d, i)
{
  m <- mean(d$hours[i])
  n <- nrow(d)
  v <- (n-1)*var(d$hours[i])/n^2
  c(m, v)
}
air.boot <- boot(aircondit, mean.fun, R = 999)
control(air.boot, index = 2, bias.adj = TRUE)
air.cont <- control(air.boot, index = 2)
# Now let us try the variance on the log scale.
air.cont1 <- control(air.boot, t0 = log(air.boot$t0[2]),
  t = log(air.boot$t[, 2]))
```

corr

*Correlation Coefficient***Description**

Calculates the weighted correlation given a data set and a set of weights.

**Usage**

```
corr(d, w = rep(1, nrow(d))/nrow(d))
```

**Arguments**

|   |  |
|---|--|
| d | A matrix with two columns corresponding to the two variables whose correlation we wish to calculate.   |
| w | A vector of weights to be applied to each pair of observations. The default is equal weights for each pair. Normalization takes place within the function so <code>sum(w)</code> need not equal 1. |

**Details**

This function finds the correlation coefficient in weighted form. This is often useful in bootstrap methods since it allows for numerical differentiation to get the empirical influence values. It is also necessary to have the statistic in this form to find ABC intervals.

**Value**

The correlation coefficient between `d[, 1]` and `d[, 2]`.

**See Also**

[cor](#)

cum3

*Calculate Third Order Cumulants***Description**

Calculates an estimate of the third cumulant, or skewness, of a vector. Also, if more than one vector is specified, a product-moment of order 3 is estimated.

**Usage**

```
cum3(a, b = a, c = a, unbiased = TRUE)
```

**Arguments**

|          |  |
|----------|--|
| a        | A vector of observations.  |
| b        | Another vector of observations, if not supplied it is set to the value of a. If supplied then it must be the same length as a. |
| c        | Another vector of observations, if not supplied it is set to the value of a. If supplied then it must be the same length as a. |
| unbiased | A logical value indicating whether the unbiased estimator should be used.  |

**Details**

The unbiased estimator uses a multiplier of  $n / ((n-1) * (n-2))$  where  $n$  is the sample size, if `unbiased` is `FALSE` then a multiplier of  $1/n$  is used. This is multiplied by `sum((a-mean(a)) * (b-mean(b)) * (c-mean(c)))` to give the required estimate.

**Value**

The required estimate.

cv.glm

*Cross-validation for Generalized Linear Models***Description**

This function calculates the estimated K-fold cross-validation prediction error for generalized linear models.

**Usage**

```
cv.glm(data, glmfit, cost, K)
```

## Arguments

|                     |   |
|---------------------|---|
| <code>data</code>   | A matrix or data frame containing the data. The rows should be cases and the columns correspond to variables, one of which is the response.   |
| <code>glmfit</code> | An object of class "glm" containing the results of a generalized linear model fitted to <code>data</code> .   |
| <code>cost</code>   | A function of two vector arguments specifying the cost function for the cross-validation. The first argument to <code>cost</code> should correspond to the observed responses and the second argument should correspond to the predicted or fitted responses from the generalized linear model. <code>cost</code> must return a non-negative scalar value. The default is the average squared error function.   |
| <code>K</code>      | The number of groups into which the data should be split to estimate the cross-validation prediction error. The value of <code>K</code> must be such that all groups are of approximately equal size. If the supplied value of <code>K</code> does not satisfy this criterion then it will be set to the closest integer which does and a warning is generated specifying the value of <code>K</code> used. The default is to set <code>K</code> equal to the number of observations in <code>data</code> which gives the usual leave-one-out cross-validation. |

## Details

The data is divided randomly into `K` groups. For each group the generalized linear model is fit to `data` omitting that group, then the function `cost` is applied to the observed responses in the group that was omitted from the fit and the prediction made by the fitted models for those observations.

When `K` is the number of observations leave-one-out cross-validation is used and all the possible splits of the data are used. When `K` is less than the number of observations the `K` splits to be used are found by randomly partitioning the data into `K` groups of approximately equal size. In this latter case a certain amount of bias is introduced. This can be reduced by using a simple adjustment (see equation 6.48 in Davison and Hinkley, 1997). The second value returned in `delta` is the estimate adjusted by this method.

## Value

The returned value is a list with the following components.

|                    |   |
|--------------------|---|
| <code>call</code>  | The original call to <code>cv.glm</code> .  |
| <code>K</code>     | The value of <code>K</code> used for the <code>K</code> -fold cross validation.   |
| <code>delta</code> | A vector of length two. The first component is the raw cross-validation estimate of prediction error. The second component is the adjusted cross-validation estimate. The adjustment is designed to compensate for the bias introduced by not using leave-one-out cross-validation. |
| <code>seed</code>  | The value of <code>.Random.seed</code> when <code>cv.glm</code> was called.   |

## Side Effects

The value of `.Random.seed` is updated.

`darwin`

*Darwin's Plant Height Differences*

---

### Description

The `darwin` data frame has 15 rows and 1 columns.

Charles Darwin conducted an experiment to examine the superiority of cross-fertilized plants over self-fertilized plants. 15 pairs of plants were used. Each pair consisted of one cross-fertilized plant and one self-fertilized plant which germinated at the same time and grew in the same pot. The plants were measured at a fixed time after planting and the difference in heights between the cross- and self-fertilized plants are recorded in eighths of an inch.

### Usage

`darwin`

**Format**

This data frame contains the following column:

**y** The difference in heights for the pairs of plants (in units of 0.125 inches).

**Source**

The data were obtained from

Fisher, R.A. (1935) *Design of Experiments*. Oliver and Boyd.

**References**

Darwin, C. (1876) *The Effects of Cross- and Self-fertilisation in the Vegetable Kingdom*. John Murray.

---

dogs

*Cardiac Data for Domestic Dogs*

---

**Description**

The dogs data frame has 7 rows and 2 columns.

Data on the cardiac oxygen consumption and left ventricular pressure were gathered on 7 domestic dogs.

**Usage**

dogs

**Format**

This data frame contains the following columns:

**mvo** Cardiac Oxygen Consumption

**lvp** Left Ventricular Pressure

**References**

Davison, A. C. and Hinkley, D. V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

---

`downs.bc`*Incidence of Down's Syndrome in British Columbia*

---

## Description

The `downs.bc` data frame has 30 rows and 3 columns.

Down's syndrome is a genetic disorder caused by an extra chromosome 21 or a part of chromosome 21 being translocated to another chromosome. The incidence of Down's syndrome is highly dependent on the mother's age and rises sharply after age 30. In the 1960's a large scale study of the effect of maternal age on the incidence of Down's syndrome was conducted at the British Columbia Health Surveillance Registry. These are the data which was collected in that study.

Mothers were classified by age. Most groups correspond to the age in years but the first group comprises all mothers with ages in the range 15-17 and the last is those with ages 46-49. No data for mothers over 50 or below 15 were collected.

## Usage

```
downs.bc
```

## Format

This data frame contains the following columns:

`age` The average age of all mothers in the age category.

`m` The total number of live births to mothers in the age category.

`r` The number of cases of Down's syndrome.

## Source

The data were obtained from

Geyer, C.J. (1991) Constrained maximum likelihood exemplified by isotonic convex logistic regression. *Journal of the American Statistical Association*, **86**, 717–724.

|       |   |
|-------|---|
| ducks | <i>Behavioral and Plumage Characteristics of Hybrid Ducks</i> |
|-------|---|

---

**Description**

The `ducks` data frame has 11 rows and 2 columns.

Each row of the data frame represents a male duck who is a second generation cross of mallard and pintail ducks. For 11 such ducks a behavioural and plumage index were calculated. These were measured on scales devised for this experiment which was to examine whether there was any link between which species the ducks resembled physically and which they resembled in behaviour. The scale for the physical appearance ranged from 0 (identical in appearance to a mallard) to 20 (identical to a pintail). The behavioural traits of the ducks were on a scale from 0 to 15 with lower numbers indicating closer to mallard-like in behaviour.

**Usage**

`ducks`

**Format**

This data frame contains the following columns:

`plumage` The index of physical appearance based on the plumage of individual ducks.

`behaviour` The index of behavioural characteristics of the ducks.

**Source**

The data were obtained from

Larsen, R.J. and Marx, M.L. (1986) *An Introduction to Mathematical Statistics and its Applications* (Second Edition). Prentice-Hall.

**References**

|             |                              |
|-------------|------------------------------|
| EEF.profile | <i>Empirical Likelihoods</i> |
|-------------|------------------------------|

---

**Description**

Construct the empirical log likelihood or empirical exponential family log likelihood for a mean.

**Usage**

```
EEF.profile(y, tmin = min(y) + 0.1, tmax = max(y) - 0.1, n.t = 25,
            u = function(y, t) y - t)
EL.profile(y, tmin = min(y) + 0.1, tmax = max(y) - 0.1, n.t = 25,
           u = function(y, t) y - t)
```

**Arguments**

|                   |   |
|-------------------|---|
| <code>y</code>    | A vector or matrix of data  |
| <code>tmin</code> | The minimum value of the range over which the likelihood should be computed. This must be larger than <code>min(y)</code> .       |
| <code>tmax</code> | The maximum value of the range over which the likelihood should be computed. This must be smaller than <code>max(y)</code> .      |
| <code>n.t</code>  | The number of points between <code>tmin</code> and <code>tmax</code> at which the value of the log-likelihood should be computed. |
| <code>u</code>    | A function of the data and the parameter.   |

**Details**

These functions calculate the log likelihood for a mean using either an empirical likelihood or an empirical exponential family likelihood. They are supplied as part of the package `boot` for demonstration purposes with the practicals in chapter 10 of Davison and Hinkley (1997). The functions are not intended for general use and are not supported as part of the `boot` package. For more general and more robust code to calculate empirical likelihoods see Professor A. B. Owen's empirical likelihood home page at the URL <https://artowen.su.domains/empirical/>

**Value**

A matrix with `n.t` rows. The first column contains the values of the parameter used. The second column of the output of `EL.profile` contains the values of the empirical log likelihood. The second and third columns of the output of `EEF.profile` contain two versions of the empirical exponential family log-likelihood. The final column of the output matrix contains the values of the Lagrange multiplier used in the optimization procedure.

empinf

*Empirical Influence Values***Description**

This function calculates the empirical influence values for a statistic applied to a data set. It allows four types of calculation, namely the infinitesimal jackknife (using numerical differentiation), the usual jackknife estimates, the ‘positive’ jackknife estimates and a method which estimates the empirical influence values using regression of bootstrap replicates of the statistic. All methods can be used with one or more samples.

**Usage**

```
empinf(boot.out = NULL, data = NULL, statistic = NULL,
       type = NULL, stype = NULL, index = 1, t = NULL,
       strata = rep(1, n), eps = 0.001, ...)
```

**Arguments**

- |           |  |
|-----------|--|
| boot.out  | A bootstrap object created by the function <code>boot</code> . If <code>type</code> is "reg" then this argument is required. For any of the other types it is an optional argument. If it is included when optional then the values of <code>data</code> , <code>statistic</code> , <code>stype</code> , and <code>strata</code> are taken from the components of <code>boot.out</code> and any values passed to <code>empinf</code> directly are ignored.   |
| data      | A vector, matrix or data frame containing the data for which empirical influence values are required. It is a required argument if <code>boot.out</code> is not supplied. If <code>boot.out</code> is supplied then <code>data</code> is set to <code>boot.out\$data</code> and any value supplied is ignored.   |
| statistic | The statistic for which empirical influence values are required. It must be a function of at least two arguments, the data set and a vector of weights, frequencies or indices. The nature of the second argument is given by the value of <code>stype</code> . Any other arguments that it takes must be supplied to <code>empinf</code> and will be passed to <code>statistic</code> unchanged. This is a required argument if <code>boot.out</code> is not supplied, otherwise its value is taken from <code>boot.out</code> and any value supplied here will be ignored.   |
| type      | The calculation type to be used for the empirical influence values. Possible values of <code>type</code> are "inf" (infinitesimal jackknife), "jack" (usual jackknife), "pos" (positive jackknife), and "reg" (regression estimation). The default value depends on the other arguments. If <code>t</code> is supplied then the default value of <code>type</code> is "reg" and <code>boot.out</code> should be present so that its frequency array can be found. If <code>t</code> is not supplied then if <code>stype</code> is "w", the default value of <code>type</code> is "inf"; otherwise, if <code>boot.out</code> is present the default is "reg". If none of these conditions apply then the default is "jack". Note that it is an error for <code>type</code> to be "reg" if <code>boot.out</code> is missing or to be "inf" if <code>stype</code> is not "w". |
| stype     | A character variable giving the nature of the second argument to <code>statistic</code> . It can take on three values: "w" (weights), "f" (frequencies), or "i" (indices). If <code>boot.out</code> is supplied the value of <code>stype</code> is set to <code>boot.out\$stype</code> and any value supplied here is ignored. Otherwise it is an optional argument which defaults to "w". If <code>type</code> is "inf" then <code>stype</code> MUST be "w".  |

|                     |   |
|---------------------|---|
| <code>index</code>  | An integer giving the position of the variable of interest in the output of <code>statistic</code> .  |
| <code>t</code>      | A vector of length <code>boot.out\$R</code> which gives the bootstrap replicates of the statistic of interest. <code>t</code> is used only when <code>type</code> is <code>reg</code> and it defaults to <code>boot.out\$t[, index]</code> .  |
| <code>strata</code> | An integer vector or a factor specifying the strata for multi-sample problems. If <code>boot.out</code> is supplied the value of <code>strata</code> is set to <code>boot.out\$strata</code> . Otherwise it is an optional argument which has default corresponding to the single sample situation. |
| <code>eps</code>    | This argument is used only if <code>type</code> is <code>"inf"</code> . In that case the value of epsilon to be used for numerical differentiation will be <code>eps</code> divided by the number of observations in <code>data</code> .  |
| <code>...</code>    | Any other arguments that <code>statistic</code> takes. They will be passed unchanged to <code>statistic</code> every time that it is called.  |

### Details

If `type` is `"inf"` then numerical differentiation is used to approximate the empirical influence values. This makes sense only for statistics which are written in weighted form (i.e. `stype` is `"w"`). If `type` is `"jack"` then the usual leave-one-out jackknife estimates of the empirical influence are returned. If `type` is `"pos"` then the positive (include-one-twice) jackknife values are used. If `type` is `"reg"` then a bootstrap object must be supplied. The regression method then works by regressing the bootstrap replicates of `statistic` on the frequency array from which they were derived. The bootstrap frequency array is obtained through a call to `boot.array`. Further details of the methods are given in Section 2.7 of Davison and Hinkley (1997).

Empirical influence values are often used frequently in nonparametric bootstrap applications. For this reason many other functions call `empinf` when they are required. Some examples of their use are for nonparametric delta estimates of variance, BCa intervals and finding linear approximations to statistics for use as control variates. They are also used for antithetic bootstrap resampling.

### Value

A vector of the empirical influence values of `statistic` applied to `data`. The values will be in the same order as the observations in `data`.

### Warning

All arguments to `empinf` must be passed using the `name = value` convention. If this is not followed then unpredictable errors can occur.

# The empirical influence values for the ratio of means in
# the city data.
ratio <- function(d, w) sum(d$x *w)/sum(d$u*w)
empinf(data = city, statistic = ratio)
city.boot <- boot(city, ratio, 499, stype="w")
empinf(boot.out = city.boot, type = "reg")

# A statistic that may be of interest in the difference of means
# problem is the t-statistic for testing equality of means. In
# the bootstrap we get replicates of the difference of means and
# the variance of that statistic and then want to use this output
# to get the empirical influence values of the t-statistic.
grav1 <- gravity[as.numeric(gravity[,2]) >= 7,]
grav.fun <- function(dat, w) {
  strata <- tapply(dat[, 2], as.numeric(dat[, 2]))
  d <- dat[, 1]
  ns <- tabulate(strata)
  w <- w/tapply(w, strata, sum)[strata]
  mns <- as.vector(tapply(d * w, strata, sum)) # drop names
  mn2 <- tapply(d * d * w, strata, sum)
  s2hat <- sum((mn2 - mns^2)/ns)
  c(mns[2] - mns[1], s2hat)
}

grav.boot <- boot(grav1, grav.fun, R = 499, stype = "w",
  strata = grav1[, 2])

# Since the statistic of interest is a function of the bootstrap
# statistics, we must calculate the bootstrap replicates and pass
# them to empinf using the t argument.
grav.z <- (grav.boot$t[,1]-grav.boot$t0[1])/sqrt(grav.boot$t[,2])
empinf(boot.out = grav.boot, t = grav.z)
```

---

envelope

---

*Confidence Envelopes for Curves*

---

**Description**

This function calculates overall and pointwise confidence envelopes for a curve based on bootstrap replicates of the curve evaluated at a number of fixed points.

**Usage**

```
envelope(boot.out = NULL, mat = NULL, level = 0.95, index = 1:ncol(mat))
```

### Arguments

|                       |   |
|-----------------------|---|
| <code>boot.out</code> | An object of class "boot" for which <code>boot.out\$t</code> contains the replicates of the curve at a number of fixed points.  |
| <code>mat</code>      | A matrix of bootstrap replicates of the values of the curve at a number of fixed points. This is a required argument if <code>boot.out</code> is not supplied and is set to <code>boot.out\$t</code> otherwise.   |
| <code>level</code>    | The confidence level of the envelopes required. The default is to find 95% confidence envelopes. It can be a scalar or a vector of length 2. If it is scalar then both the pointwise and the overall envelopes are found at that level. If is a vector then the first element gives the level for the pointwise envelope and the second gives the level for the overall envelope. |
| <code>index</code>    | The numbers of the columns of <code>mat</code> which contain the bootstrap replicates. This can be used to ensure that other statistics which may have been calculated in the bootstrap are not considered as values of the function.   |

### Details

The pointwise envelope is found by simply looking at the quantiles of the replicates at each point. The overall error for that envelope is then calculated using equation (4.17) of Davison and Hinkley (1997). A sequence of pointwise envelopes is then found until one of them has overall error approximately equal to the level required. If no such envelope can be found then the envelope returned will just contain the extreme values of each column of `mat`.

### Value

A list with the following components :

|                      |   |
|----------------------|---|
| <code>point</code>   | A matrix with two rows corresponding to the values of the upper and lower pointwise confidence envelope at the same points as the bootstrap replicates were calculated. |
| <code>overall</code> | A matrix similar to <code>point</code> but containing the envelope which controls the overall error.  |
| <code>k.pt</code>    | The quantiles used for the pointwise envelope.  |
| <code>err.pt</code>  | A vector with two components, the first gives the pointwise error rate for the pointwise envelope, and the second the overall error rate for that envelope.             |
| <code>k.ov</code>    | The quantiles used for the overall envelope.  |
| <code>err.ov</code>  | A vector with two components, the first gives the pointwise error rate for the overall envelope, and the second the overall error rate for that envelope.               |
| <code>err.nom</code> | A vector of length 2 giving the nominal error rates for the pointwise and the overall envelopes.  |

---

exp.tilt

*Exponential Tilting*

---

## Description

This function calculates exponentially tilted multinomial distributions such that the resampling distributions of the linear approximation to a statistic have the required means.

## Usage

```
exp.tilt(L, theta = NULL, t0 = 0, lambda = NULL,
        strata = rep(1, length(L)))
```

## Arguments

|                     |  |
|---------------------|--|
| <code>L</code>      | The empirical influence values for the statistic of interest based on the observed data. The length of <code>L</code> should be the same as the size of the original data set. Typically <code>L</code> will be calculated by a call to <code>empinf</code> .  |
| <code>theta</code>  | The value at which the tilted distribution is to be centred. This is not required if <code>lambda</code> is supplied but is needed otherwise.  |
| <code>t0</code>     | The current value of the statistic. The default is that the statistic equals 0.  |
| <code>lambda</code> | The Lagrange multiplier(s). For each value of <code>lambda</code> a multinomial distribution is found with probabilities proportional to $\exp(\text{lambda} * L)$ . In general <code>lambda</code> is not known and so <code>theta</code> would be supplied, and the corresponding value of <code>lambda</code> found. If both <code>lambda</code> and <code>theta</code> are supplied then <code>lambda</code> is ignored and the multipliers for tilting to <code>theta</code> are found. |
| <code>strata</code> | A vector or factor of the same length as <code>L</code> giving the strata for the observed data and the empirical influence values <code>L</code> .  |

## Details

Exponential tilting involves finding a set of weights for a data set to ensure that the bootstrap distribution of the linear approximation to a statistic of interest has mean `theta`. The weights chosen to achieve this are given by `p[j]` proportional to  $\exp(\lambda L[j]/n)$ , where `n` is the number of data points. `lambda` is then chosen to make the mean of the bootstrap distribution, of the linear approximation to the statistic of interest, equal to the required value `theta`. Thus `lambda` is defined as the solution of a nonlinear equation. The equation is solved by minimizing the Euclidean distance between the left and right hand sides of the equation using the function `nlmin`. If this minimum is not equal to zero then the method fails.

Typically exponential tilting is used to find suitable weights for importance resampling. If a small tail probability or quantile of the distribution of the statistic of interest is required then a more efficient simulation is to centre the resampling distribution close to the point of interest and then use the functions `imp.prob` or `imp.quantile` to estimate the required quantity.

Another method of achieving a similar shifting of the distribution is through the use of `smooth.f`. The function `tilt.boot` uses `exp.tilt` or `smooth.f` to find the weights for a tilted bootstrap.

## Value

A list with the following components :

|                     |  |
|---------------------|--|
| <code>p</code>      | The tilted probabilities. There will be <code>m</code> distributions where <code>m</code> is the length of <code>theta</code> (or <code>lambda</code> if supplied). If <code>m</code> is 1 then <code>p</code> is a vector of length <code>(L)</code> probabilities. If <code>m</code> is greater than 1 then <code>p</code> is a matrix with <code>m</code> rows, each of which contain length <code>(L)</code> probabilities. In this case the vector <code>p[i, ]</code> is the distribution tilted to <code>theta[i]</code> . <code>p</code> is in the form required by the argument <code>weights</code> of the function <code>boot</code> for importance resampling. |
| <code>lambda</code> | The Lagrange multiplier used in the equation to determine the tilted probabilities. <code>lambda</code> is a vector of the same length as <code>theta</code> .   |
| <code>theta</code>  | The values of <code>theta</code> to which the distributions have been tilted. In general this will be the input value of <code>theta</code> but if <code>lambda</code> was supplied then this is the vector of the corresponding <code>theta</code> values.  |

mn2 <- tapply(d * d * w, strata, sum)
s2hat <- sum(mn2 - mns^2)/ns
c(mns[2]-mns[1], s2hat, (mns[2]-mns[1]-orig)/sqrt(s2hat))
}
grav.z0 <- grav.fun(grav1, rep(1, 26), 0)
grav.L <- empinf(data = grav1, statistic = grav.fun, stype = "w",
                 strata = grav1[,2], index = 3, orig = grav.z0[1])
grav.tilt <- exp.tilt(grav.L, grav.z0[3], strata = grav1[,2])
boot(grav1, grav.fun, R = 499, stype = "w", weights = grav.tilt$p,
     strata = grav1[,2], orig = grav.z0[1])

```

fir

*Counts of Balsam-fir Seedlings*

## Description

The `fir` data frame has 50 rows and 3 columns.

The number of balsam-fir seedlings in each quadrant of a grid of 50 five foot square quadrants were counted. The grid consisted of 5 rows of 10 quadrants in each row.

## Usage

```
fir
```

## Format

This data frame contains the following columns:

`count` The number of seedlings in the quadrant.

`row` The row number of the quadrant.

`col` The quadrant number within the row.

## Source

---

freq.array

*Bootstrap Frequency Arrays*

---

### Description

Take a matrix of indices for nonparametric bootstrap resamples and return the frequencies of the original observations in each resample.

### Usage

```
freq.array(i.array)
```

### Arguments

`i.array` This will be an matrix of integers between 1 and `n`, where `n` is the number of observations in a data set. The matrix will have `n` columns and `R` rows where `R` is the number of bootstrap resamples. Such matrices are found by `boot` when doing nonparametric bootstraps. They can also be found after a bootstrap has been run through the function `boot.array`.

### Value

A matrix of the same dimensions as the input matrix. Each row of the matrix corresponds to a single bootstrap resample. Each column of the matrix corresponds to one of the original observations and specifies its frequency in each bootstrap resample. Thus the first column tells us how often the first observation appeared in each bootstrap resample. Such frequency arrays are often useful for diagnostic purposes such as the jackknife-after-bootstrap plot. They are also necessary for the regression estimates of empirical influence values and for finding importance sampling weights.

frets

*Head Dimensions in Brothers*

---

### Description

The `frets` data frame has 25 rows and 4 columns.

The data consist of measurements of the length and breadth of the heads of pairs of adult brothers in 25 randomly sampled families. All measurements are expressed in millimetres.

### Usage

```
frets
```

**Format**

This data frame contains the following columns:

- l1 The head length of the eldest son.
- b1 The head breadth of the eldest son.
- l2 The head length of the second son.
- b2 The head breadth of the second son.

**Source**

The data were obtained from

Frets, G.P. (1921) Heredity of head form in man. *Genetica*, **3**, 193.

---

glm.diag

---

*Generalized Linear Model Diagnostics*

---

**Description**

Calculates jackknife deviance residuals, standardized deviance residuals, standardized Pearson residuals, approximate Cook statistic, leverage and estimated dispersion.

**Usage**

```
glm.diag(glmfit)
```

**Arguments**

glmfit            glmfit is a glm.object - the result of a call to glm()

**Value**

Returns a list with the following components

- |      |  |
|------|--|
| res  | The vector of jackknife deviance residuals.  |
| rd   | The vector of standardized deviance residuals.   |
| rp   | The vector of standardized Pearson residuals.  |
| cook | The vector of approximate Cook statistics.   |
| h    | The vector of leverages of the observations.   |
| sd   | The value used to standardize the residuals. This is the estimate of residual standard deviation in the Gaussian family and is the square root of the estimated shape parameter in the Gamma family. In all other cases it is 1. |

**Note**

See the help for `glm.diag.plots` for an example of the use of `glm.diag`.

|                             |  |
|-----------------------------|--|
| <code>glm.diag.plots</code> | <i>Diagnostics plots for generalized linear models</i> |
|-----------------------------|--|

---

**Description**

Makes plot of jackknife deviance residuals against linear predictor, normal scores plots of standardized deviance residuals, plot of approximate Cook statistics against leverage/(1-leverage), and case plot of Cook statistic.

**Usage**

```
glm.diag.plots(glmfit, glmdiag = glm.diag(glmfit), subset = NULL,
               iden = FALSE, labels = NULL, ret = FALSE)
```

**Arguments**

|                      |   |
|----------------------|---|
| <code>glmfit</code>  | glm.object : the result of a call to <code>glm()</code>   |
| <code>glmdiag</code> | Diagnostics of <code>glmfit</code> obtained from a call to <code>glm.diag</code> . If it is not supplied then it is calculated.   |
| <code>subset</code>  | Subset of data for which <code>glm</code> fitting performed: should be the same as the <code>subset</code> option used in the call to <code>glm()</code> which generated <code>glmfit</code> . Needed only if the <code>subset=</code> option was used in the call to <code>glm</code> .  |
| <code>iden</code>    | A logical argument. If <code>TRUE</code> then, after the plots are drawn, the user will be prompted for an integer between 0 and 4. A positive integer will select a plot and invoke <code>identify()</code> on that plot. After exiting <code>identify()</code> , the user is again prompted, this loop continuing until the user responds to the prompt with 0. If <code>iden</code> is <code>FALSE</code> (default) the user cannot interact with the plots. |
| <code>labels</code>  | A vector of labels for use with <code>identify()</code> if <code>iden</code> is <code>TRUE</code> . If it is not supplied then the labels are derived from <code>glmfit</code> .  |
| <code>ret</code>     | A logical argument indicating if <code>glmdiag</code> should be returned. The default is <code>FALSE</code> .   |

## Details

The diagnostics required for the plots are calculated by `glm.diag`. These are then used to produce the four plots on the current graphics device.

The plot on the top left is a plot of the jackknife deviance residuals against the fitted values.

The plot on the top right is a normal QQ plot of the standardized deviance residuals. The dotted line is the expected line if the standardized residuals are normally distributed, i.e. it is the line with intercept 0 and slope 1.

The bottom two panels are plots of the Cook statistics. On the left is a plot of the Cook statistics against the standardized leverages. In general there will be two dotted lines on this plot. The horizontal line is at  $8/(n-2p)$  where  $n$  is the number of observations and  $p$  is the number of parameters estimated. Points above this line may be points with high influence on the model. The vertical line is at  $2p/(n-2p)$  and points to the right of this line have high leverage compared to the variance of the raw residual at that point. If all points are below the horizontal line or to the left of the vertical line then the line is not shown.

The final plot again shows the Cook statistic this time plotted against case number enabling us to find which observations are influential.

Use of `iden=T` is encouraged for proper exploration of these four plots as a guide to how well the model fits the data and whether certain observations have an unduly large effect on parameter estimates.

## Value

If `ret` is `TRUE` then the value of `glm.diag` is returned otherwise there is no returned value.

## Side Effects

The current device is cleared and four plots are plotted by use of `split.screen(c(2,2))`. If `iden` is `TRUE`, interactive identification of points is enabled. All screens are closed, but not cleared, on termination of the function.

# In this example we look at the leukaemia data which was looked at in
# Example 7.1 of Davison and Hinkley (1997)
data(leuk, package = "MASS")
leuk.mod <- glm(time ~ ag-1+log10(wbc), family = Gamma(log), data = leuk)
leuk.diag <- glm.diag(leuk.mod)
glm.diag.plots(leuk.mod, leuk.diag)
```

gravity

*Acceleration Due to Gravity***Description**

The `gravity` data frame has 81 rows and 2 columns.

The `grav` data set has 26 rows and 2 columns.

Between May 1934 and July 1935, the National Bureau of Standards in Washington D.C. conducted a series of experiments to estimate the acceleration due to gravity,  $g$ , at Washington. Each experiment produced a number of replicate estimates of  $g$  using the same methodology. Although the basic method remained the same for all experiments, that of the reversible pendulum, there were changes in configuration.

The `gravity` data frame contains the data from all eight experiments. The `grav` data frame contains the data from the experiments 7 and 8. The data are expressed as deviations from 980.000 in centimetres per second squared.

**Usage**

```
gravity
```

**Format**

This data frame contains the following columns:

`g` The deviation of the estimate from 980.000 centimetres per second squared.

`series` A factor describing from which experiment the estimate was derived.

**Source**

The data were obtained from

Cressie, N. (1982) Playing safe with misweighted means. *Journal of the American Statistical Association*, **77**, 754–759.

**References**

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

hirose

*Failure Time of PET Film***Description**

The `hirose` data frame has 44 rows and 3 columns.

PET film is used in electrical insulation. In this accelerated life test the failure times for 44 samples in gas insulated transformers. 4 different voltage levels were used.

**Usage**

```
hirose
```

**Format**

This data frame contains the following columns:

`volt` The voltage (in kV).

`time` The failure or censoring time in hours.

`cens` The censoring indicator; 1 means right-censored data.

**Source**

The data were obtained from

Hirose, H. (1993) Estimation of threshold stress in accelerated life-testing. *IEEE Transactions on Reliability*, **42**, 650–657.

**References**

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

---

Imp.Estimates

*Importance Sampling Estimates*

---

**Description**

Central moment, tail probability, and quantile estimates for a statistic under importance resampling.

**Usage**

```
imp.moments(boot.out = NULL, index = 1, t = boot.out$t[, index],
            w = NULL, def = TRUE, q = NULL)
imp.prob(boot.out = NULL, index = 1, t0 = boot.out$t0[index],
         t = boot.out$t[, index], w = NULL, def = TRUE, q = NULL)
imp.quantile(boot.out = NULL, alpha = NULL, index = 1,
            t = boot.out$t[, index], w = NULL, def = TRUE, q = NULL)
```

**Arguments**

|                       |  |
|-----------------------|--|
| <code>boot.out</code> | A object of class "boot" generated by a call to <code>boot</code> or <code>tilt.boot</code> . Use of these functions makes sense only when the bootstrap resampling used unequal weights for the observations. If the importance weights <code>w</code> are not supplied then <code>boot.out</code> is a required argument. It is also required if <code>t</code> is not supplied. |
| <code>alpha</code>    | The alpha levels for the required quantiles. The default is to calculate the 1%, 2.5%, 5%, 10%, 90%, 95%, 97.5% and 99% quantiles.   |
| <code>index</code>    | The index of the variable of interest in the output of <code>boot.out\$statistic</code> . This is not used if the argument <code>t</code> is supplied.   |

|                  |   |
|------------------|---|
| <code>t0</code>  | The values at which tail probability estimates are required. For each value <code>t0[i]</code> the function will estimate the bootstrap cdf evaluated at <code>t0[i]</code> . If <code>imp.prob</code> is called without the argument <code>t0</code> then the bootstrap cdf evaluated at the observed value of the statistic is found.   |
| <code>t</code>   | The bootstrap replicates of a statistic. By default these are taken from the bootstrap output object <code>boot.out</code> but they can be supplied separately if required (e.g. when the statistic of interest is a function of the calculated values in <code>boot.out</code> ). Either <code>boot.out</code> or <code>t</code> must be supplied.   |
| <code>w</code>   | The importance resampling weights for the bootstrap replicates. If they are not supplied then <code>boot.out</code> must be supplied, in which case the importance weights are calculated by a call to <code>imp.weights</code> .   |
| <code>def</code> | A logical value indicating whether a defensive mixture is to be used for weight calculation. This is used only if <code>w</code> is missing and it is passed unchanged to <code>imp.weights</code> to calculate <code>w</code> .  |
| <code>q</code>   | A vector of probabilities specifying the resampling distribution from which any estimates should be found. In general this would correspond to the usual bootstrap resampling distribution which gives equal weight to each of the original observations. The estimates depend on this distribution only through the importance weights <code>w</code> so this argument is ignored if <code>w</code> is supplied. If <code>w</code> is missing then <code>q</code> is passed as an argument to <code>imp.weights</code> and used to find <code>w</code> . |

### Value

A list with the following components :

|                    |   |
|--------------------|---|
| <code>alpha</code> | The alpha levels used for the quantiles, if <code>imp.quantile</code> is used.  |
| <code>t0</code>    | The values at which the tail probabilities are estimated, if <code>imp.prob</code> is used.   |
| <code>raw</code>   | The raw importance resampling estimates. For <code>imp.moments</code> this has length 2, the first component being the estimate of the mean and the second being the variance estimate. For <code>imp.prob</code> , <code>raw</code> is of the same length as <code>t0</code> , and for <code>imp.quantile</code> it is of the same length as <code>alpha</code> .          |
| <code>rat</code>   | The ratio importance resampling estimates. In this method the weights <code>w</code> are rescaled to have average value one before they are used. The format of this vector is the same as <code>raw</code> .   |
| <code>reg</code>   | The regression importance resampling estimates. In this method the weights which are used are derived from a regression of $t \cdot w$ on <code>w</code> . This choice of weights can be shown to minimize the variance of the weights and also the Euclidean distance of the weights from the uniform weights. The format of this vector is the same as <code>raw</code> . |

as.data.frame(grav.q)
```

---

imp.weights

---

*Importance Sampling Weights*

---

**Description**

This function calculates the importance sampling weight required to correct for simulation from a distribution with probabilities  $p$  when estimates are required assuming that simulation was from an alternative distribution with probabilities  $q$ .

**Usage**

```
imp.weights(boot.out, def = TRUE, q = NULL)
```

## Arguments

|                       |   |
|-----------------------|---|
| <code>boot.out</code> | A object of class "boot" generated by <code>boot</code> or <code>tilt.boot</code> . Typically the bootstrap simulations would have been done using importance resampling and we wish to do our calculations under the assumption of sampling with equal probabilities.  |
| <code>def</code>      | A logical variable indicating whether the defensive mixture distribution weights should be calculated. This makes sense only in the case where the replicates in <code>boot.out</code> were simulated under a number of different distributions. If this is the case then the defensive mixture weights use a mixture of the distributions used in the bootstrap. The alternative is to calculate the weights for each replicate using knowledge of the distribution from which the bootstrap resample was generated. |
| <code>q</code>        | A vector of probabilities specifying the resampling distribution from which we require inferences to be made. In general this would correspond to the usual bootstrap resampling distribution which gives equal weight to each of the original observations and this is the default. <code>q</code> must have length equal to the number of observations in the <code>boot.out\$data</code> and all elements of <code>q</code> must be positive.  |

## Details

The importance sampling weight for a bootstrap replicate with frequency vector  $\mathbf{f}$  is given by  $\text{prod}((q/p)^{\mathbf{f}})$ . This reweights the replicates so that estimates can be found as if the bootstrap resamples were generated according to the probabilities  $q$  even though, in fact, they came from the distribution  $p$ .

## Value

A vector of importance weights of the same length as `boot.out$t`. These weights can then be used to reweight `boot.out$t` so that estimates can be found as if the simulations were from a distribution with probabilities  $q$ .

## Note

See the example in the help for `imp.moments` for an example of using `imp.weights`.

---

inv.logit

*Inverse Logit Function*

---

**Description**

Given a numeric object return the inverse logit of the values.

**Usage**

```
inv.logit(x)
```

**Arguments**

`x` A numeric object. Missing values (NAs) are allowed.

**Details**

The inverse logit is defined by  $\exp(x) / (1 + \exp(x))$ . Values in `x` of `-Inf` or `Inf` return logits of 0 or 1 respectively. Any NAs in the input will also be NAs in the output.

**Value**

An object of the same type as `x` containing the inverse logits of the input values.

**See Also**

[logit](#), [plogis](#) for which this is a wrapper.

---

islay

*Jura Quartzite Azimuths on Islay*

---

**Description**

The `islay` data frame has 18 rows and 1 columns.

Measurements were taken of paleocurrent azimuths from the Jura Quartzite on the Scottish island of Islay.

**Usage**

```
islay
```

**Format**

This data frame contains the following column:

`theta` The angle of the azimuth in degrees East of North.

## Source

---

|                 |  |
|-----------------|--|
| jack.after.boot | <i>Jackknife-after-Bootstrap Plots</i> |
|-----------------|--|

---

## Description

This function calculates the jackknife influence values from a bootstrap output object and plots the corresponding jackknife-after-bootstrap plot.

## Usage

```
jack.after.boot (boot.out, index = 1, t = NULL, L = NULL,
                useJ = TRUE, stinf = TRUE, alpha = NULL,
                main = "", ylab = NULL, ...)
```

## Arguments

|          |   |
|----------|---|
| boot.out | An object of class "boot" which would normally be created by a call to <a href="#">boot</a> . It should represent a nonparametric bootstrap. For reliable results <code>boot.out\$R</code> should be reasonably large.  |
| index    | The index of the statistic of interest in the output of <code>boot.out\$statistic</code> .  |
| t        | A vector of length <code>boot.out\$R</code> giving the bootstrap replicates of the statistic of interest. This is useful if the statistic of interest is a function of the calculated bootstrap output. If it is not supplied then the default is <code>boot.out\$t[, index]</code> .   |
| L        | The empirical influence values for the statistic of interest. These are used only if <code>useJ</code> is <code>FALSE</code> . If they are not supplied and are needed, they are calculated by a call to <code>empinf</code> . If <code>L</code> is supplied then it is assumed that they are the infinitesimal jackknife values. |
| useJ     | A logical variable indicating if the jackknife influence values calculated from the bootstrap replicates should be used. If <code>FALSE</code> the empirical influence values are used. The default is <code>TRUE</code> .  |
| stinf    | A logical variable indicating whether to standardize the jackknife values before plotting them. If <code>TRUE</code> then the jackknife values used are divided by their standard error.  |
| alpha    | The quantiles at which the plots are required. The default is <code>c(0.05, 0.1, 0.16, 0.5, 0.84, 0.9, 0.95)</code> .   |
| main     | A character string giving the main title for the plot.  |

|      |  |
|------|--|
| ylab | The label for the Y axis. If the default values of <code>alpha</code> are used and <code>ylab</code> is not supplied then a label indicating which percentiles are plotted is used. If <code>alpha</code> is supplied then the default label will not say which percentiles were used.   |
| ...  | Any extra arguments required by <code>boot.out\$statistic</code> . These are required only if <code>useJ</code> is <code>FALSE</code> and <code>L</code> is not supplied, in which case they are passed to <code>empinf</code> for use in calculation of the empirical influence values. |

## Details

The centred jackknife quantiles for each observation are estimated from those bootstrap samples in which the particular observation did not appear. These are then plotted against the influence values. If `useJ` is `TRUE` then the influence values are found in the same way as the difference between the mean of the statistic in the samples excluding the observations and the mean in all samples. If `useJ` is `FALSE` then empirical influence values are calculated by calling `empinf`.

The resulting plots are useful diagnostic tools for looking at the way individual observations affect the bootstrap output.

The plot will consist of a number of horizontal dotted lines which correspond to the quantiles of the centred bootstrap distribution. For each data point the quantiles of the bootstrap distribution calculated by omitting that point are plotted against the (possibly standardized) jackknife values. The observation number is printed below the plots. To make it easier to see the effect of omitting points on quantiles, the plotted quantiles are joined by line segments. These plots provide a useful diagnostic tool in establishing the effect of individual observations on the bootstrap distribution. See the references below for some guidelines on the interpretation of the plots.

## Value

There is no returned value but a plot is generated on the current graphics display.

## Side Effects

A plot is created on the current graphics device.

## References

iv <- solve(v)
iv.d <- sqrt(diag(iv))
iv <- - diag(1/iv.d) %*% iv %*% diag(1/iv.d)
q <- NULL
n <- nrow(v)
for (i in 1:(n-1))
  q <- rbind( q, c(v[i, 1:i], iv[i, (i+1):n]) )
q <- rbind( q, v[n, ] )
diag(q) <- round(diag(q))
q
}
d <- data[i, ]
v <- pcorr(d)
c(v[1,], v[2,], v[3,], v[4,])
}
frets.boot <- boot(log(as.matrix(frets)), frets.fun, R = 999)
# we will concentrate on the partial correlation between head breadth
# for the first son and head length for the second. This is the 7th
# element in the output of frets.fun so we set index = 7
jack.after.boot(frets.boot, useJ = FALSE, stinf = FALSE, index = 7)

```

k3.linear

*Linear Skewness Estimate*

## Description

Estimates the skewness of a statistic from its empirical influence values.

## Usage

```
k3.linear(L, strata = NULL)
```

## Arguments

|                     |  |
|---------------------|--|
| <code>L</code>      | Vector of the empirical influence values of a statistic. These will usually be calculated by a call to <code>empinf</code> .     |
| <code>strata</code> | A numeric vector or factor specifying which observations (and hence which components of <code>L</code> ) come from which strata. |

## Value

The skewness estimate calculated from `L`.

## References

Davison, A. C. and Hinkley, D. V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

## See Also

[empinf](#), [linear.approx](#), [var.linear](#)

## Examples

```
# To estimate the skewness of the ratio of means for the city data.
ratio <- function(d, w) sum(d$x * w) / sum(d$u * w)
k3.linear(empinf(data = city, statistic = ratio))
```

linear.approx

*Linear Approximation of Bootstrap Replicates*

## Description

This function takes a bootstrap object and for each bootstrap replicate it calculates the linear approximation to the statistic of interest for that bootstrap sample.

## Usage

```
linear.approx(boot.out, L = NULL, index = 1, type = NULL,
              t0 = NULL, t = NULL, ...)
```

## Arguments

|                       |  |
|-----------------------|--|
| <code>boot.out</code> | An object of class "boot" representing a nonparametric bootstrap. It will usually be created by the function <code>boot</code> .   |
| <code>L</code>        | A vector containing the empirical influence values for the statistic of interest. If it is not supplied then <code>L</code> is calculated through a call to <code>empinf</code> .  |
| <code>index</code>    | The index of the variable of interest within the output of <code>boot.out\$statistic</code> .  |
| <code>type</code>     | This gives the type of empirical influence values to be calculated. It is not used if <code>L</code> is supplied. The possible types of empirical influence values are described in the help for <a href="#">empinf</a> .  |
| <code>t0</code>       | The observed value of the statistic of interest. The input value is used only if one of <code>t</code> or <code>L</code> is also supplied. The default value is <code>boot.out\$t0[index]</code> . If <code>t0</code> is supplied but neither <code>t</code> nor <code>L</code> are supplied then <code>t0</code> is set to <code>boot.out\$t0[index]</code> and a warning is generated. |
| <code>t</code>        | A vector of bootstrap replicates of the statistic of interest. If <code>t0</code> is missing then <code>t</code> is not used, otherwise it is used to calculate the empirical influence values (if they are not supplied in <code>L</code> ).  |
| <code>...</code>      | Any extra arguments required by <code>boot.out\$statistic</code> . These are needed if <code>L</code> is not supplied as they are used by <code>empinf</code> to calculate empirical influence values.   |

## Details

The linear approximation to a bootstrap replicate with frequency vector `f` is given by  $t_0 + \sum (L * f) / n$  in the one sample with an easy extension to the stratified case. The frequencies are found by calling `boot.array`.

## Value

A vector of length `boot.out$R` with the linear approximations to the statistic of interest for each of the bootstrap samples.

## References

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

lines.saddle.distn *Add a Saddlepoint Approximation to a Plot*

---

## Description

This function adds a line corresponding to a saddlepoint density or distribution function approximation to the current plot.

## Usage

```
## S3 method for class 'saddle.distn'
lines(x, dens = TRUE, h = function(u) u, J = function(u) 1,
      npts = 50, lty = 1, ...)
```

## Arguments

|      |   |
|------|---|
| x    | An object of class "saddle.distn" (see <a href="#">saddle.distn.object</a> representing a saddlepoint approximation to a distribution.  |
| dens | A logical variable indicating whether the saddlepoint density (TRUE; the default) or the saddlepoint distribution function (FALSE) should be plotted.   |
| h    | Any transformation of the variable that is required. Its first argument must be the value at which the approximation is being performed and the function must be vectorized.  |
| J    | When dens=TRUE this function specifies the Jacobian for any transformation that may be necessary. The first argument of J must the value at which the approximation is being performed and the function must be vectorized. If h is supplied J must also be supplied and both must have the same argument list. |
| npts | The number of points to be used for the plot. These points will be evenly spaced over the range of points used in finding the saddlepoint approximation.  |
| lty  | The line type to be used.   |
| ...  | Any additional arguments to h and J.  |

## Details

The function uses `smooth.spline` to produce the saddlepoint curve. When `dens=TRUE` the spline is on the log scale and when `dens=FALSE` it is on the probit scale.

## Value

`sad.d` is returned invisibly.

## Side Effects

A line is added to the current plot.

## References

**Examples**

```
# In this example we show how a plot such as that in Figure 9.9 of
# Davison and Hinkley (1997) may be produced. Note the large number of
# bootstrap replicates required in this example.
expdata <- rexp(12)
vfun <- function(d, i) {
  n <- length(d)
  (n-1)/n*var(d[i])
}
exp.boot <- boot(expdata,vfun, R = 9999)
exp.L <- (expdata - mean(expdata))^2 - exp.boot$t0
exp.tL <- linear.approx(exp.boot, L = exp.L)
hist(exp.tL, nclass = 50, probability = TRUE)
exp.t0 <- c(0, sqrt(var(exp.boot$t)))
exp.sp <- saddle.distn(A = exp.L/12,wdist = "m", t0 = exp.t0)

# The saddlepoint approximation in this case is to the density of
# t-t0 and so t0 must be added for the plot.
lines(exp.sp, h = function(u, t0) u+t0, J = function(u, t0) 1,
      t0 = exp.boot$t0)
```

---

logit

*Logit of Proportions*

---

**Description**

This function calculates the logit of proportions.

**Usage**

```
logit(p)
```

**Arguments**

**p** A numeric Splus object, all of whose values are in the range [0,1]. Missing values (NAs) are allowed.

**Details**

If any elements of **p** are outside the unit interval then an error message is generated. Values of **p** equal to 0 or 1 (to within machine precision) will return `-Inf` or `Inf` respectively. Any NAs in the input will also be NAs in the output.

**Value**

A numeric object of the same type as **p** containing the logits of the input values.

**See Also**

[inv.logit](#), [qlogis](#) for which this is a wrapper.

manaus

*Average Heights of the Rio Negro river at Manaus*

## Description

The manaus time series is of class "ts" and has 1080 observations on one variable.

The data values are monthly averages of the daily stages (heights) of the Rio Negro at Manaus. Manaus is 18km upstream from the confluence of the Rio Negro with the Amazon but because of the tiny slope of the water surface and the lower courses of its flatland affluents, they may be regarded as a good approximation of the water level in the Amazon at the confluence. The data here cover 90 years from January 1903 until December 1992.

The Manaus gauge is tied in with an arbitrary bench mark of 100m set in the steps of the Municipal Prefecture; gauge readings are usually referred to sea level, on the basis of a mark on the steps leading to the Parish Church (Matriz), which is assumed to lie at an altitude of 35.874 m according to observations made many years ago under the direction of Samuel Pereira, an engineer in charge of the Manaus Sanitation Committee Whereas such an altitude cannot, by any means, be considered to be a precise datum point, observations have been provisionally referred to it. The measurements are in metres.

## Source

The data were kindly made available by Professors H. O'Reilly Sternberg and D. R. Brillinger of the University of California at Berkeley.

melanoma

*Survival from Malignant Melanoma*

## Description

The melanoma data frame has 205 rows and 7 columns.

The data consist of measurements made on patients with malignant melanoma. Each patient had their tumour removed by surgery at the Department of Plastic Surgery, University Hospital of Odense, Denmark during the period 1962 to 1977. The surgery consisted of complete removal of the tumour together with about 2.5cm of the surrounding skin. Among the measurements taken were the thickness of the tumour and whether it was ulcerated or not. These are thought to be important prognostic variables in that patients with a thick and/or ulcerated tumour have an increased chance of death from melanoma. Patients were followed until the end of 1977.

**Usage**

```
melanoma
```

**Format**

This data frame contains the following columns:

`time` Survival time in days since the operation, possibly censored.

`status` The patients status at the end of the study. 1 indicates that they had died from melanoma, 2 indicates that they were still alive and 3 indicates that they had died from causes unrelated to their melanoma.

`sex` The patients sex; 1=male, 0=female.

`age` Age in years at the time of the operation.

`year` Year of operation.

`thickness` Tumour thickness in mm.

`ulcer` Indicator of ulceration; 1=present, 0=absent.

**Note**

This dataset is not related to the dataset in the **lattice** package with the same name.

**Source**

The data were obtained from

---

```
motor
```

*Data from a Simulated Motorcycle Accident*

---

**Description**

The `motor` data frame has 94 rows and 4 columns. The rows are obtained by removing replicate values of `time` from the dataset `mcycle`. Two extra columns are added to allow for strata with a different residual variance in each stratum.

**Usage**

```
motor
```

**Format**

This data frame contains the following columns:

`times` The time in milliseconds since impact.

`accel` The recorded head acceleration (in g).

`strata` A numeric column indicating to which of the three strata (numbered 1, 2 and 3) the observations belong.

`v` An estimate of the residual variance for the observation. `v` is constant within the strata but a different estimate is used for each of the three strata.

**Source**

The data were obtained from

Silverman, B.W. (1985) Some aspects of the spline smoothing approach to non-parametric curve fitting. *Journal of the Royal Statistical Society, B*, **47**, 1–52.

---

neuro

*Neurophysiological Point Process Data*

---

**Description**

`neuro` is a matrix containing times of observed firing of a neuron in windows of 250ms either side of the application of a stimulus to a human subject. Each row of the matrix is a replication of the experiment and there were a total of 469 replicates.

**Note**

There are a lot of missing values in the matrix as different numbers of firings were observed in different replicates. The number of firings observed varied from 2 to 6.

**Source**

The data were collected and kindly made available by Dr. S.J. Boniface of the Neurophysiology Unit at the Radcliffe Infirmary, Oxford.

**References**

---

nitrofen*Toxicity of Nitrofen in Aquatic Systems*

---

## Description

The `nitrofen` data frame has 50 rows and 5 columns.

Nitrofen is a herbicide that was used extensively for the control of broad-leaved and grass weeds in cereals and rice. Although it is relatively non-toxic to adult mammals, nitrofen is a significant tetragen and mutagen. It is also acutely toxic and reproductively toxic to cladoceran zooplankton. Nitrofen is no longer in commercial use in the U.S., having been the first pesticide to be withdrawn due to tetragenic effects.

The data here come from an experiment to measure the reproductive toxicity of nitrofen on a species of zooplankton (*Ceriodaphnia dubia*). 50 animals were randomized into batches of 10 and each batch was put in a solution with a measured concentration of nitrofen. Then the number of live offspring in each of the three broods to each animal was recorded.

## Usage

```
nitrofen
```

## Format

This data frame contains the following columns:

`conc` The nitrofen concentration in the solution (mug/litre).

`brood1` The number of live offspring in the first brood.

`brood2` The number of live offspring in the second brood.

`brood3` The number of live offspring in the third brood.

`total` The total number of live offspring in the first three broods.

## Source

The data were obtained from

Bailer, A.J. and Oris, J.T. (1994) Assessing toxicity of pollutants in aquatic systems. In *Case Studies in Biometry*. N. Lange, L. Ryan, L. Billard, D. Brillinger, L. Conquest and J. Greenhouse (editors), 25–40. John Wiley.

nodal

*Nodal Involvement in Prostate Cancer***Description**

The `nodal` data frame has 53 rows and 7 columns.

The treatment strategy for a patient diagnosed with cancer of the prostate depend highly on whether the cancer has spread to the surrounding lymph nodes. It is common to operate on the patient to get samples from the nodes which can then be analysed under a microscope but clearly it would be preferable if an accurate assessment of nodal involvement could be made without surgery.

For a sample of 53 prostate cancer patients, a number of possible predictor variables were measured before surgery. The patients then had surgery to determine nodal involvement. It was required to see if nodal involvement could be accurately predicted from the predictor variables and which ones were most important.

**Usage**

```
nodal
```

**Format**

This data frame contains the following columns:

`m` A column of ones.

`r` An indicator of nodal involvement.

`aged` The patients age dichotomized into less than 60 (0) and 60 or over 1.

`stage` A measurement of the size and position of the tumour observed by palpitation with the fingers via the rectum. A value of 1 indicates a more serious case of the cancer.

`grade` Another indicator of the seriousness of the cancer, this one is determined by a pathology reading of a biopsy taken by needle before surgery. A value of 1 indicates a more serious case of the cancer.

`xray` A third measure of the seriousness of the cancer taken from an X-ray reading. A value of 1 indicates a more serious case of the cancer.

`acid` The level of acid phosphatase in the blood serum.

**Source**

The data were obtained from

Brown, B.W. (1980) Prediction analysis for binary data. In *Biostatistics Casebook*. R.G. Miller, B. Efron, B.W. Brown and L.E. Moses (editors), 3–18. John Wiley.

**References**

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

norm.ci

*Normal Approximation Confidence Intervals***Description**

Using the normal approximation to a statistic, calculate equi-tailed two-sided confidence intervals.

**Usage**

```
norm.ci(boot.out = NULL, conf = 0.95, index = 1, var.t0 = NULL,
        t0 = NULL, t = NULL, L = NULL, h = function(t) t,
        hdot = function(t) 1, hinv = function(t) t)
```

**Arguments**

|                       |  |
|-----------------------|--|
| <code>boot.out</code> | A bootstrap output object returned from a call to <code>boot</code> . If <code>t0</code> is missing then <code>boot.out</code> is a required argument. It is also required if both <code>var.t0</code> and <code>t</code> are missing.   |
| <code>conf</code>     | A scalar or vector containing the confidence level(s) of the required interval(s).   |
| <code>index</code>    | The index of the statistic of interest within the output of a call to <code>boot.out\$statistic</code> . It is not used if <code>boot.out</code> is missing, in which case <code>t0</code> must be supplied.   |
| <code>var.t0</code>   | The variance of the statistic of interest. If it is not supplied then <code>var(t)</code> is used.   |
| <code>t0</code>       | The observed value of the statistic of interest. If it is missing then it is taken from <code>boot.out</code> which is required in that case.  |
| <code>t</code>        | Bootstrap replicates of the variable of interest. These are used to estimate the variance of the statistic of interest if <code>var.t0</code> is not supplied. The default value is <code>boot.out\$t[, index]</code> .  |
| <code>L</code>        | The empirical influence values for the statistic of interest. These are used to calculate <code>var.t0</code> if neither <code>var.t0</code> nor <code>boot.out</code> are supplied. If a transformation is supplied through <code>h</code> then the influence values must be for the untransformed statistic <code>t0</code> .                                |
| <code>h</code>        | A function defining a monotonic transformation, the intervals are calculated on the scale of <code>h(t)</code> and the inverse function <code>hinv</code> is applied to the resulting intervals. <code>h</code> must be a function of one variable only and must be vectorized. The default is the identity function.  |
| <code>hdot</code>     | A function of one argument returning the derivative of <code>h</code> . It is a required argument if <code>h</code> is supplied and is used for approximating the variance of <code>h(t0)</code> . The default is the constant function 1.   |
| <code>hinv</code>     | A function, like <code>h</code> , which returns the inverse of <code>h</code> . It is used to transform the intervals calculated on the scale of <code>h(t)</code> back to the original scale. The default is the identity function. If <code>h</code> is supplied but <code>hinv</code> is not, then the intervals returned will be on the transformed scale. |

## Details

It is assumed that the statistic of interest has an approximately normal distribution with variance `var.t0` and so a confidence interval of length  $2 * \text{qnorm}((1 + \text{conf}) / 2) * \text{sqrt}(\text{var.t0})$  is found. If `boot.out` or `t` are supplied then the interval is bias-corrected using the bootstrap bias estimate, and so the interval would be centred at  $2 * t_0 - \text{mean}(t)$ . Otherwise the interval is centred at `t0`.

## Value

If `length(conf)` is 1 then a vector containing the confidence level and the endpoints of the interval is returned. Otherwise, the returned value is a matrix where each row corresponds to a different confidence level.

## Note

This function is primarily designed to be called by `boot.ci` to calculate the normal approximation after a bootstrap but it can also be used without doing any bootstrap calculations as long as `t0` and `var.t0` can be supplied. See the examples below.

## References

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

## Examples

```
# In Example 5.1 of Davison and Hinkley (1997), normal approximation
# confidence intervals are found for the air-conditioning data.
air.mean <- mean(aircondit$hours)
air.n <- nrow(aircondit)
air.v <- air.mean^2/air.n
norm.ci(t0 = air.mean, var.t0 = air.v)
exp(norm.ci(t0 = log(air.mean), var.t0 = 1/air.n)[2:3])

# Now a more complicated example - the ratio estimate for the city data.
ratio <- function(d, w)
  sum(d$x * w)/sum(d$u * w)
city.v <- var.linear(empinf(data = city, statistic = ratio))
norm.ci(t0 = ratio(city, rep(0.1, 10)), var.t0 = city.v)
```

## Description

The `nuclear` data frame has 32 rows and 11 columns.

The data relate to the construction of 32 light water reactor (LWR) plants constructed in the U.S.A in the late 1960's and early 1970's. The data was collected with the aim of predicting the cost of construction of further LWR plants. 6 of the power plants had partial turnkey guarantees and it is possible that, for these plants, some manufacturers' subsidies may be hidden in the quoted capital costs.

## Usage

```
nuclear
```

## Format

This data frame contains the following columns:

`cost` The capital cost of construction in millions of dollars adjusted to 1976 base.

`date` The date on which the construction permit was issued. The data are measured in years since January 1 1990 to the nearest month.

`t1` The time between application for and issue of the construction permit.

`t2` The time between issue of operating license and construction permit.

`cap` The net capacity of the power plant (MWe).

`pr` A binary variable where 1 indicates the prior existence of a LWR plant at the same site.

`ne` A binary variable where 1 indicates that the plant was constructed in the north-east region of the U.S.A.

`ct` A binary variable where 1 indicates the use of a cooling tower in the plant.

`bw` A binary variable where 1 indicates that the nuclear steam supply system was manufactured by Babcock-Wilcox.

`cum.n` The cumulative number of power plants constructed by each architect-engineer.

`pt` A binary variable where 1 indicates those plants with partial turnkey guarantees.

## Source

The data were obtained from

Cox, D.R. and Snell, E.J. (1981) *Applied Statistics: Principles and Examples*. Chapman and Hall.

## References

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

paulsen

*Neurotransmission in Guinea Pig Brains***Description**

The paulsen data frame has 346 rows and 1 columns.

Sections were prepared from the brain of adult guinea pigs. Spontaneous currents that flowed into individual brain cells were then recorded and the peak amplitude of each current measured. The aim of the experiment was to see if the current flow was quantal in nature (i.e. that it is not a single burst but instead is built up of many smaller bursts of current). If the current was indeed quantal then it would be expected that the distribution of the current amplitude would be multimodal with modes at regular intervals. The modes would be expected to decrease in magnitude for higher current amplitudes.

**Usage**

```
paulsen
```

**Format**

This data frame contains the following column:

y The current flowing into individual brain cells. The currents are measured in pico-amperes.

**Source**

The data were kindly made available by Dr. O. Paulsen from the Department of Pharmacology at the University of Oxford.

Paulsen, O. and Heggelund, P. (1994) The quantal size at retinogeniculate synapses determined from spontaneous and evoked EPSCs in guinea-pig thalamic slices. *Journal of Physiology*, **480**, 505–511.

**References**

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

plot.boot

*Plots of the Output of a Bootstrap Simulation***Description**

This takes a bootstrap object and produces plots for the bootstrap replicates of the variable of interest.

**Usage**

```
## S3 method for class 'boot'
plot(x, index = 1, t0 = NULL, t = NULL, jack = FALSE,
     qdist = "norm", nclass = NULL, df, ...)
```

## Arguments

|                     |   |
|---------------------|---|
| <code>x</code>      | An object of class "boot" returned from one of the bootstrap generation functions.  |
| <code>index</code>  | The index of the variable of interest within the output of <code>boot.out</code> . This is ignored if <code>t</code> and <code>t0</code> are supplied.  |
| <code>t0</code>     | The original value of the statistic. This defaults to <code>boot.out\$t0[index]</code> unless <code>t</code> is supplied when it defaults to <code>NULL</code> . In that case no vertical line is drawn on the histogram.                               |
| <code>t</code>      | The bootstrap replicates of the statistic. Usually this will take on its default value of <code>boot.out\$t[, index]</code> , however it may be useful sometimes to supply a different set of values which are a function of <code>boot.out\$t</code> . |
| <code>jack</code>   | A logical value indicating whether a jackknife-after-bootstrap plot is required. The default is not to produce such a plot.   |
| <code>qdist</code>  | The distribution against which the Q-Q plot should be drawn. At present "norm" (normal distribution - the default) and "chisq" (chi-squared distribution) are the only possible values.   |
| <code>nclass</code> | An integer giving the number of classes to be used in the bootstrap histogram. The default is the integer between 10 and 100 closest to <code>ceiling(length(t)/25)</code> .  |
| <code>df</code>     | If <code>qdist</code> is "chisq" then this is the degrees of freedom for the chi-squared distribution to be used. It is a required argument in that case.   |
| <code>...</code>    | When <code>jack</code> is TRUE additional parameters to <code>jack.after.boot</code> can be supplied. See the help file for <code>jack.after.boot</code> for details of the possible parameters.  |

## Details

This function will generally produce two side-by-side plots. The left plot will be a histogram of the bootstrap replicates. Usually the breaks of the histogram will be chosen so that `t0` is at a breakpoint and all intervals are of equal length. A vertical dotted line indicates the position of `t0`. This cannot be done if `t` is supplied but `t0` is not and so, in that case, the breakpoints are computed by `hist` using the `nclass` argument and no vertical line is drawn.

The second plot is a Q-Q plot of the bootstrap replicates. The order statistics of the replicates can be plotted against normal or chi-squared quantiles. In either case the expected line is also plotted. For the normal, this will have intercept `mean(t)` and slope `sqrt(var(t))` while for the chi-squared it has intercept 0 and slope 1.

If `jack` is TRUE a third plot is produced beneath these two. That plot is the jackknife-after-bootstrap plot. This plot may only be requested when nonparametric simulation has been used. See `jack.after.boot` for further details of this plot.

## Value

`boot.out` is returned invisibly.

## Side Effects

All screens are closed and cleared and a number of plots are produced on the current graphics device. Screens are closed but not cleared at termination of this function.

poisons

*Animal Survival Times*

---

### Description

The `poisons` data frame has 48 rows and 3 columns.

The data form a 3x4 factorial experiment, the factors being three poisons and four treatments. Each combination of the two factors was used for four animals, the allocation to animals having been completely randomized.

### Usage

```
poisons
```

### Format

This data frame contains the following columns:

`time` The survival time of the animal in units of 10 hours.

`poison` A factor with levels 1, 2 and 3 giving the type of poison used.

`treat` A factor with levels A, B, C and D giving the treatment.

### Source

The data were obtained from

Box, G.E.P. and Cox, D.R. (1964) An analysis of transformations (with Discussion). *Journal of the Royal Statistical Society, B*, **26**, 211–252.

---

polar

*Pole Positions of New Caledonian Laterites*

---

### Description

The `polar` data frame has 50 rows and 2 columns.

The data are the pole positions from a paleomagnetic study of New Caledonian laterites.

### Usage

```
polar
```

**Format**

This data frame contains the following columns:

- lat The latitude (in degrees) of the pole position. Note that all latitudes are negative as the axis is taken to be in the lower hemisphere.
- long The longitude (in degrees) of the pole position.

**Source**

The data were obtained from

Fisher, N.I., Lewis, T. and Embleton, B.J.J. (1987) *Statistical Analysis of Spherical Data*. Cambridge University Press.

|                         |  |
|-------------------------|--|
| <code>print.boot</code> | <i>Print a Summary of a Bootstrap Object</i> |
|-------------------------|--|

---

**Description**

This is a method for the function `print()` for objects of the class "boot" created by a call to `boot`, `censboot`, `tilt.boot` or `tsboot`.

**Usage**

```
## S3 method for class 'boot'
print(x, digits = getOption("digits"),
      index = 1:ncol(boot.out$t), ...)
```

**Arguments**

- `x` A bootstrap output object of class "boot" generated by one of the bootstrap functions.
- `digits` The number of digits to be printed in the summary statistics.
- `index` Indices indicating for which elements of the bootstrap output summary statistics are required.
- `...` further arguments passed to or from other methods.

**Details**

For each statistic calculated in the bootstrap the original value and the bootstrap estimates of its bias and standard error are printed. If `boot.out$t0` is missing (such as when it was created by a call to `tsboot` with `orig.t = FALSE`) the bootstrap mean and standard error are printed. If resampling was done using importance resampling weights, then the bootstrap estimates are reweighted as if uniform resampling had been done. The ratio importance sampling estimates are used and if there were a number of distributions then defensive mixture distributions are used. In this case an extra column with the mean of the observed bootstrap statistics is also printed.

**Value**

The bootstrap object is returned invisibly.

**See Also**

`boot`, `censboot`, `imp.moments`, `plot.boot`, `tilt.boot`, `tsboot`

---

`print.bootci`

*Print Bootstrap Confidence Intervals*

---

**Description**

This is a method for the function `print()` to print objects of the class "bootci".

**Usage**

```
## S3 method for class 'bootci'
print(x, hinv = NULL, ...)
```

**Arguments**

|                   |   |
|-------------------|---|
| <code>x</code>    | The output from a call to <code>boot.ci</code> .                                |
| <code>hinv</code> | A transformation to be made to the interval end-points before they are printed. |
| <code>...</code>  | further arguments passed to or from other methods.                              |

**Details**

This function prints out the results from `boot.ci` in a "nice" format. It also notes whether the scale of the intervals is the original scale of the input to `boot.ci` or a different scale and whether the calculations were done on a transformed scale. It also looks at the order statistics that were used in calculating the intervals. If the smallest or largest values were used then it prints a message

```
Warning : Intervals used Extreme Quantiles
```

Such intervals should be considered very unstable and not relied upon for inferences. Even if the extreme values are not used, it is possible that the intervals are unstable if they used quantiles close to the extreme values. The function alerts the user to intervals which use the upper or lower 10 order statistics with the message

```
Some intervals may be unstable
```

**Value**

The object `ci.out` is returned invisibly.

**See Also**

`boot.ci`

---

```
print.saddle.distn
```

*Print Quantiles of Saddlepoint Approximations*

---

### Description

This is a method for the function `print()` to print objects of class `"saddle.distn"`.

### Usage

```
## S3 method for class 'saddle.distn'  
print(x, ...)
```

### Arguments

|                  |   |
|------------------|---|
| <code>x</code>   | An object of class <code>"saddle.distn"</code> created by a call to <code>saddle.distn</code> . |
| <code>...</code> | further arguments passed to or from other methods.  |

### Details

The quantiles of the saddlepoint approximation to the distribution are printed along with the original call and some other useful information.

### Value

The input is returned invisibly.

### See Also

[lines.saddle.distn](#), [saddle.distn](#)

---

```
print.simplex
```

*Print Solution to Linear Programming Problem*

---

### Description

This is a method for the function `print()` to print objects of class `"simplex"`.

### Usage

```
## S3 method for class 'simplex'  
print(x, ...)
```

### Arguments

|                  |   |
|------------------|---|
| <code>x</code>   | An object of class <code>"simplex"</code> created by calling the function <code>simplex</code> to solve a linear programming problem. |
| <code>...</code> | further arguments passed to or from other methods.  |

### Details

The coefficients of the objective function are printed. If a solution to the linear programming problem was found then the solution and the optimal value of the objective function are printed. If a feasible solution was found but the maximum number of iterations was exceeded then the last feasible solution and the objective function value at that point are printed. If no feasible solution could be found then a message stating that is printed.

### Value

`x` is returned silently.

### See Also

[simplex](#)

remission

*Cancer Remission and Cell Activity*

---

### Description

The `remission` data frame has 27 rows and 3 columns.

### Usage

```
remission
```

### Format

This data frame contains the following columns:

- `LI` A measure of cell activity.
- `m` The number of patients in each group (all values are actually 1 here).
- `r` The number of patients (out of `m`) who went into remission.

### Source

The data were obtained from

Freeman, D.H. (1987) *Applied Categorical Data Analysis*. Marcel Dekker.

### References

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

## Description

This function calculates a saddlepoint approximation to the distribution of a linear combination of  $\mathbf{W}$  at a particular point  $u$ , where  $\mathbf{W}$  is a vector of random variables. The distribution of  $\mathbf{W}$  may be multinomial (default), Poisson or binary. Other distributions are possible also if the adjusted cumulant generating function and its second derivative are given. Conditional saddlepoint approximations to the distribution of one linear combination given the values of other linear combinations of  $\mathbf{W}$  can be calculated for  $\mathbf{W}$  having binary or Poisson distributions.

## Usage

```
saddle(A = NULL, u = NULL, wdist = "m", type = "simp", d = NULL,
       d1 = 1, init = rep(0.1, d), mu = rep(0.5, n), LR = FALSE,
       strata = NULL, K.adj = NULL, K2 = NULL)
```

## Arguments

|                     |  |
|---------------------|--|
| <code>A</code>      | A vector or matrix of known coefficients of the linear combinations of $\mathbf{W}$ . It is a required argument unless <code>K.adj</code> and <code>K2</code> are supplied, in which case it is ignored.   |
| <code>u</code>      | The value at which it is desired to calculate the saddlepoint approximation to the distribution of the linear combination of $\mathbf{W}$ . It is a required argument unless <code>K.adj</code> and <code>K2</code> are supplied, in which case it is ignored.   |
| <code>wdist</code>  | The distribution of $\mathbf{W}$ . This can be one of "m" (multinomial), "p" (Poisson), "b" (binary) or "o" (other). If <code>K.adj</code> and <code>K2</code> are given <code>wdist</code> is set to "o".   |
| <code>type</code>   | The type of saddlepoint approximation. Possible types are "simp" for simple saddlepoint and "cond" for the conditional saddlepoint. When <code>wdist</code> is "o" or "m", <code>type</code> is automatically set to "simp", which is the only type of saddlepoint currently implemented for those distributions.  |
| <code>d</code>      | This specifies the dimension of the whole statistic. This argument is required only when <code>wdist</code> = "o" and defaults to 1 if not supplied in that case. For other distributions it is set to <code>ncol(A)</code> .  |
| <code>d1</code>     | When <code>type</code> is "cond" this is the dimension of the statistic of interest which must be less than <code>length(u)</code> . Then the saddlepoint approximation to the conditional distribution of the first <code>d1</code> linear combinations given the values of the remaining combinations is found. Conditional distribution function approximations can only be found if the value of <code>d1</code> is 1. |
| <code>init</code>   | Used if <code>wdist</code> is either "m" or "o", this gives initial values to <code>nlmin</code> which is used to solve the saddlepoint equation.  |
| <code>mu</code>     | The values of the parameters of the distribution of $\mathbf{W}$ when <code>wdist</code> is "m", "p" or "b". <code>mu</code> must be of the same length as $\mathbf{W}$ (i.e. <code>nrow(A)</code> ). The default is that all values of <code>mu</code> are equal and so the elements of $\mathbf{W}$ are identically distributed.   |
| <code>LR</code>     | If TRUE then the Lugananni-Rice approximation to the cdf is used, otherwise the approximation used is based on Barndorff-Nielsen's $r^*$ .   |
| <code>strata</code> | The strata for stratified data.  |

|                    |   |
|--------------------|---|
| <code>K.adj</code> | The adjusted cumulant generating function used when <code>wdist</code> is "o". This is a function of a single parameter, <code>zeta</code> , which calculates $K(zeta) - u * zeta$ , where $K(zeta)$ is the cumulant generating function of $W$ .   |
| <code>K2</code>    | This is a function of a single parameter <code>zeta</code> which returns the matrix of second derivatives of $K(zeta)$ for use when <code>wdist</code> is "o". If <code>K.adj</code> is given then this must be given also. It is called only once with the calculated solution to the saddlepoint equation being passed as the argument. This argument is ignored if <code>K.adj</code> is not supplied. |

### Details

If `wdist` is "o" or "m", the saddlepoint equations are solved using `nlmin` to minimize `K.adj` with respect to its parameter `zeta`. For the Poisson and binary cases, a generalized linear model is fitted such that the parameter estimates solve the saddlepoint equations. The response variable 'y' for the `glm` must satisfy the equation  $t(A) \%*\%y = u(t())$  being the transpose function). Such a vector can be found as a feasible solution to a linear programming problem. This is done by a call to `simplex`. The covariate matrix for the `glm` is given by `A`.

### Value

A list consisting of the following components

|                        |  |
|------------------------|--|
| <code>spa</code>       | The saddlepoint approximations. The first value is the density approximation and the second value is the distribution function approximation.                                  |
| <code>zeta.hat</code>  | The solution to the saddlepoint equation. For the conditional saddlepoint this is the solution to the saddlepoint equation for the numerator.                                  |
| <code>zeta2.hat</code> | If <code>type</code> is "cond" this is the solution to the saddlepoint equation for the denominator. This component is not returned for any other value of <code>type</code> . |

### Examples

```
# To evaluate the bootstrap distribution of the mean failure time of
# air-conditioning equipment at 80 hours
saddle(A = aircondit$hours/12, u = 80)

# Alternatively this can be done using a conditional poisson
saddle(A = cbind(aircondit$hours/12,1), u = c(80, 12),
```

```

wdist = "p", type = "cond")

# To use the Lugananni-Rice approximation to this
saddle(A = cbind(aircondit$hours/12,1), u = c(80, 12),
        wdist = "p", type = "cond",
        LR = TRUE)

# Example 9.16 of Davison and Hinkley (1997) calculates saddlepoint
# approximations to the distribution of the ratio statistic for the
# city data. Since the statistic is not in itself a linear combination
# of random Variables, its distribution cannot be found directly.
# Instead the statistic is expressed as the solution to a linear
# estimating equation and hence its distribution can be found. We
# get the saddlepoint approximation to the pdf and cdf evaluated at
# t = 1.25 as follows.
jacobian <- function(dat,t,zeta)
{
  p <- exp(zeta*(dat$x-t*dat$u))
  abs(sum(dat$u*p)/sum(p))
}
city.sp1 <- saddle(A = city$x-1.25*city$u, u = 0)
city.sp1$spa[1] <- jacobian(city, 1.25, city.sp1$zeta.hat) * city.sp1$spa[1]
city.sp1

```

saddle.distn

*Saddlepoint Distribution Approximations for Bootstrap Statistics*

## Description

Approximate an entire distribution using saddlepoint methods. This function can calculate simple and conditional saddlepoint distribution approximations for a univariate quantity of interest. For the simple saddlepoint the quantity of interest is a linear combination of  $\mathbf{W}$  where  $\mathbf{W}$  is a vector of random variables. For the conditional saddlepoint we require the distribution of one linear combination given the values of any number of other linear combinations. The distribution of  $\mathbf{W}$  must be one of multinomial, Poisson or binary. The primary use of this function is to calculate quantiles of bootstrap distributions using saddlepoint approximations. Such quantiles are required by the function `control` to approximate the distribution of the linear approximation to a statistic.

## Usage

```

saddle.distn(A, u = NULL, alpha = NULL, wdist = "m",
             type = "simp", npts = 20, t = NULL, t0 = NULL,
             init = rep(0.1, d), mu = rep(0.5, n), LR = FALSE,
             strata = NULL, ...)

```

## Arguments

**A** This is a matrix of known coefficients or a function which returns such a matrix. If a function then its first argument must be the point  $t$  at which a saddlepoint is required. The most common reason for  $A$  being a function would be if the statistic is not itself a linear combination of the  $\mathbf{W}$  but is the solution to a linear estimating equation.

|                     |   |
|---------------------|---|
| <code>u</code>      | If <code>A</code> is a function then <code>u</code> must also be a function returning a vector with length equal to the number of columns of the matrix returned by <code>A</code> . Usually all components other than the first will be constants as the other components are the values of the conditioning variables. If <code>A</code> is a matrix with more than one column (such as when <code>wdist = "cond"</code> ) then <code>u</code> should be a vector with length one less than <code>ncol(A)</code> . In this case <code>u</code> specifies the values of the conditioning variables. If <code>A</code> is a matrix with one column or a vector then <code>u</code> is not used.                                 |
| <code>alpha</code>  | The alpha levels for the quantiles of the distribution which should be returned. By default the 0.1, 0.5, 1, 2.5, 5, 10, 20, 50, 80, 90, 95, 97.5, 99, 99.5 and 99.9 percentiles are calculated.  |
| <code>wdist</code>  | The distribution of <b>W</b> . Possible values are "m" (multinomial), "p" (Poisson), or "b" (binary).   |
| <code>type</code>   | The type of saddlepoint to be used. Possible values are "simp" (simple saddlepoint) and "cond" (conditional). If <code>wdist</code> is "m", <code>type</code> is set to "simp".   |
| <code>npts</code>   | The number of points at which the saddlepoint approximation should be calculated and then used to fit the spline.   |
| <code>t</code>      | A vector of points at which the saddlepoint approximations are calculated. These points should extend beyond the extreme quantiles required but still be in the possible range of the bootstrap distribution. The observed value of the statistic should not be included in <code>t</code> as the distribution function approximation breaks down at that point. The points should, however cover the entire effective range of the distribution including close to the centre. If <code>t</code> is supplied then <code>npts</code> is set to <code>length(t)</code> . When <code>t</code> is not supplied, the function attempts to find the effective range of the distribution and then selects points to cover this range. |
| <code>t0</code>     | If <code>t</code> is not supplied then a vector of length 2 should be passed as <code>t0</code> . The first component of <code>t0</code> should be the centre of the distribution and the second should be an estimate of spread (such as a standard error). These two are then used to find the effective range of the distribution. The range finding mechanism does rely on an accurate estimate of location in <code>t0[1]</code> .   |
| <code>init</code>   | When <code>wdist</code> is "m", this vector should contain the initial values to be passed to <code>nlmin</code> when it is called to solve the saddlepoint equations.  |
| <code>mu</code>     | The vector of parameter values for the distribution. The default is that the components of <b>W</b> are identically distributed.  |
| <code>LR</code>     | A logical flag. When <code>LR</code> is <code>TRUE</code> the Lugananni-Rice cdf approximations are calculated and used to fit the spline. Otherwise the cdf approximations used are based on Barndorff-Nielsen's $r^*$ .   |
| <code>strata</code> | A vector giving the strata when the rows of <code>A</code> relate to stratified data. This is used only when <code>wdist</code> is "m".   |
| <code>...</code>    | When <code>A</code> and <code>u</code> are functions any additional arguments are passed unchanged each time one of them is called.   |

## Details

The range at which the saddlepoint is used is such that the cdf approximation at the endpoints is more extreme than required by the extreme values of `alpha`. The lower endpoint is found by evaluating the saddlepoint at the points `t0[1]-2*t0[2]`, `t0[1]-4*t0[2]`, `t0[1]-8*t0[2]` etc. until a point is found with a cdf approximation less than `min(alpha)/10`, then a bisection method is used to find the endpoint which has cdf approximation in the range `(min(alpha)/1000, min(alpha)/10)`. Then a number of, equally spaced, points are chosen

between the lower endpoint and `t0[1]` until a total of `npts/2` approximations have been made. The remaining `npts/2` points are chosen to the right of `t0[1]` in a similar manner. Any points which are very close to the centre of the distribution are then omitted as the cdf approximations are not reliable at the centre. A smoothing spline is then fitted to the probit of the saddlepoint distribution function approximations at the remaining points and the required quantiles are predicted from the spline.

Sometimes the function will terminate with the message "Unable to find range". There are two main reasons why this may occur. One is that the distribution is too discrete and/or the required quantiles too extreme, this can cause the function to be unable to find a point within the allowable range which is beyond the extreme quantiles. Another possibility is that the value of `t0[2]` is too small and so too many steps are required to find the range. The first problem cannot be solved except by asking for less extreme quantiles, although for very discrete distributions the approximations may not be very good. In the second case using a larger value of `t0[2]` will usually solve the problem.

### Value

The returned value is an object of class "saddle.distn". See the help file for [saddle.distn.object](#) for a description of such an object.

ufn <- function(t, data) c(0, sum(data$u), 10)
city.t0 <- c(mean(city$x)/mean(city$u), sqrt(city.v))
saddle.distn(A = Afn, u = ufn, wdist = "p", type = "cond", t0 = city.t0,
             data = city)
```

---

saddle.distn.object

*Saddlepoint Distribution Approximation Objects*

---

## Description

Class of objects that result from calculating saddlepoint distribution approximations by a call to `saddle.distn`.

## Generation

This class of objects is returned from calls to the function `saddle.distn`.

## Methods

The class "saddle.distn" has methods for the functions `lines` and `print`.

## Structure

Objects of class "saddle.distn" are implemented as a list with the following components.

**quantiles** A matrix with 2 columns. The first column contains the probabilities alpha and the second column contains the estimated quantiles of the distribution at those probabilities derived from the spline.

**points** A matrix of evaluations of the saddlepoint approximation. The first column contains the values of  $t$  which were used, the second and third contain the density and cdf approximations at those points and the rest of the columns contain the solutions to the saddlepoint equations. When `type` is "simp", there is only one of those. When `type` is "cond" there are  $2*d-1$  where  $d$  is the number of columns in  $A$  or the output of  $A(t, \dots \{ \})$ . The first  $d$  of these correspond to the numerator and the remainder correspond to the denominator.

**distn** An object of class `smooth.spline`. This corresponds to the spline fitted to the saddlepoint cdf approximations in `points` in order to approximate the entire distribution. For the structure of the object see `smooth.spline`.

**call** The original call to `saddle.distn` which generated the object.

**LR** A logical variable indicating whether the Lugananni-Rice approximations were used.

salinity

*Water Salinity and River Discharge***Description**

The `salinity` data frame has 28 rows and 4 columns.

Biweekly averages of the water salinity and river discharge in Pamlico Sound, North Carolina were recorded between the years 1972 and 1977. The data in this set consists only of those measurements in March, April and May.

**Usage**

```
salinity
```

**Format**

This data frame contains the following columns:

`sal` The average salinity of the water over two weeks.

`lag` The average salinity of the water lagged two weeks. Since only spring is used, the value of `lag` is not always equal to the previous value of `sal`.

`trend` A factor indicating in which of the 6 biweekly periods between March and May, the observations were taken. The levels of the factor are from 0 to 5 with 0 being the first two weeks in March.

`dis` The amount of river discharge during the two weeks for which `sal` is the average salinity.

**Source**

The data were obtained from

Ruppert, D. and Carroll, R.J. (1980) Trimmed least squares estimation in the linear model. *Journal of the American Statistical Association*, **75**, 828–838.

**References**

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

simplex

*Simplex Method for Linear Programming Problems***Description**

This function will optimize the linear function  $a \% \% x$  subject to the constraints  $A1 \% \% x \leq b1$ ,  $A2 \% \% x \geq b2$ ,  $A3 \% \% x = b3$  and  $x \geq 0$ . Either maximization or minimization is possible but the default is minimization.

**Usage**

```
simplex(a, A1 = NULL, b1 = NULL, A2 = NULL, b2 = NULL, A3 = NULL,
       b3 = NULL, maxi = FALSE, n.iter = n + 2 * m, eps = 1e-10)
```

**Arguments**

|                     |   |
|---------------------|---|
| <code>a</code>      | A vector of length <code>n</code> which gives the coefficients of the objective function.   |
| <code>A1</code>     | An <code>m1</code> by <code>n</code> matrix of coefficients for the $\leq$ type of constraints.   |
| <code>b1</code>     | A vector of length <code>m1</code> giving the right hand side of the $\leq$ constraints. This argument is required if <code>A1</code> is given and ignored otherwise. All values in <code>b1</code> must be non-negative.   |
| <code>A2</code>     | An <code>m2</code> by <code>n</code> matrix of coefficients for the $\geq$ type of constraints.   |
| <code>b2</code>     | A vector of length <code>m2</code> giving the right hand side of the $\geq$ constraints. This argument is required if <code>A2</code> is given and ignored otherwise. All values in <code>b2</code> must be non-negative. Note that the constraints $x \geq 0$ are included automatically and so should not be repeated here. |
| <code>A3</code>     | An <code>m3</code> by <code>n</code> matrix of coefficients for the equality constraints.   |
| <code>b3</code>     | A vector of length <code>m3</code> giving the right hand side of equality constraints. This argument is required if <code>A3</code> is given and ignored otherwise. All values in <code>b3</code> must be non-negative.   |
| <code>maxi</code>   | A logical flag which specifies minimization if <code>FALSE</code> (default) and maximization otherwise. If <code>maxi</code> is <code>TRUE</code> then the maximization problem is recast as a minimization problem by changing the objective function coefficients to their negatives.                                       |
| <code>n.iter</code> | The maximum number of iterations to be conducted in each phase of the simplex method. The default is <code>n+2*(m1+m2+m3)</code> .  |
| <code>eps</code>    | The floating point tolerance to be used in tests of equality.   |

**Details**

The method employed by this function is the two phase tableau simplex method. If there are  $\geq$  or equality constraints an initial feasible solution is not easy to find. To find a feasible solution an artificial variable is introduced into each  $\geq$  or equality constraint and an auxiliary objective function is defined as the sum of these artificial variables. If a feasible solution to the set of constraints exists then the auxiliary objective will be minimized when all of the artificial variables are 0. These are then discarded and the original problem solved starting at the solution to the auxiliary problem. If the only constraints are of the  $\leq$  form, the origin is a feasible solution and so the first stage can be omitted.

**Value**

An object of class "simplex": see `simplex.object`.

**Note**

The method employed here is suitable only for relatively small systems. Also if possible the number of constraints should be reduced to a minimum in order to speed up the execution time which is approximately proportional to the cube of the number of constraints. In particular if there are any constraints of the form `x[i] >= b2[i]` they should be omitted by setting `x[i] = x[i] - b2[i]`, changing all the constraints and the objective function accordingly and then transforming back after the solution has been found.

```
# This example is taken from Exercise 7.5 of Gill, Murray and Wright (1991).
enj <- c(200, 6000, 3000, -200)
fat <- c(800, 6000, 1000, 400)
vitx <- c(50, 3, 150, 100)
vity <- c(10, 10, 75, 100)
vitz <- c(150, 35, 75, 5)
simplex(a = enj, A1 = fat, b1 = 13800, A2 = rbind(vitx, vity, vitz),
       b2 = c(600, 300, 550), maxi = TRUE)
```

---

simplex.object

*Linear Programming Solution Objects*

---

## Description

Class of objects that result from solving a linear programming problem using `simplex`.

## Generation

This class of objects is returned from calls to the function `simplex`.

## Methods

The class `"saddle.distn"` has a method for the function `print`.

## Structure

Objects of class `"simplex"` are implemented as a list with the following components.

**soln** The values of  $x$  which optimize the objective function under the specified constraints provided those constraints are jointly feasible.

**solved** This indicates whether the problem was solved. A value of  $-1$  indicates that no feasible solution could be found. A value of  $0$  that the maximum number of iterations was reached without termination of the second stage. This may indicate an unbounded function or simply that more iterations are needed. A value of  $1$  indicates that an optimal solution has been found.

**value** The value of the objective function at `soln`.

**val.aux** This is `NULL` if a feasible solution is found. Otherwise it is a positive value giving the value of the auxiliary objective function when it was minimized.

**obj** The original coefficients of the objective function.

**a** The objective function coefficients re-expressed such that the basic variables have coefficient zero.

**a.aux** This is `NULL` if a feasible solution is found. Otherwise it is the re-expressed auxiliary objective function at the termination of the first phase of the simplex method.

**A** The final constraint matrix which is expressed in terms of the non-basic variables. If a feasible solution is found then this will have dimensions  $m_1+m_2+m_3$  by  $n+m_1+m_2$ , where the final  $m_1+m_2$  columns correspond to slack and surplus variables. If no feasible solution is found there will be an additional  $m_1+m_2+m_3$  columns for the artificial variables introduced to solve the first phase of the problem.

**basic** The indices of the basic (non-zero) variables in the solution. Indices between  $n+1$  and  $n+m_1$  correspond to slack variables, those between  $n+m_1+1$  and  $n+m_2$  correspond to surplus variables and those greater than  $n+m_2$  are artificial variables. Indices greater than  $n+m_2$  should occur only if `solved` is `-1` as the artificial variables are discarded in the second stage of the simplex method.

**slack** The final values of the  $m_1$  slack variables which arise when the " $\leq$ " constraints are re-expressed as the equalities  $A1 \% \% x + \text{slack} = b1$ .

**surplus** The final values of the  $m_2$  surplus variables which arise when the " $\leq$ " constraints are re-expressed as the equalities  $A2 \% \% x - \text{surplus} = b2$ .

**artificial** This is `NULL` if a feasible solution can be found. If no solution can be found then this contains the values of the  $m_1+m_2+m_3$  artificial variables which minimize their sum subject to the original constraints. A feasible solution exists only if all of the artificial variables can be made 0 simultaneously.

---

smooth.f

*Smooth Distributions on Data Points*

---

### Description

This function uses the method of frequency smoothing to find a distribution on a data set which has a required value, `theta`, of the statistic of interest. The method results in distributions which vary smoothly with `theta`.

### Usage

```
smooth.f(theta, boot.out, index = 1, t = boot.out$t[, index],
         width = 0.5)
```

### Arguments

|                       |   |
|-----------------------|---|
| <code>theta</code>    | The required value for the statistic of interest. If <code>theta</code> is a vector, a separate distribution will be found for each element of <code>theta</code> .   |
| <code>boot.out</code> | A bootstrap output object returned by a call to <code>boot</code> .   |
| <code>index</code>    | The index of the variable of interest in the output of <code>boot.out\$statistic</code> . This argument is ignored if <code>t</code> is supplied. <code>index</code> must be a scalar.  |
| <code>t</code>        | The bootstrap values of the statistic of interest. This must be a vector of length <code>boot.out\$R</code> and the values must be in the same order as the bootstrap replicates in <code>boot.out</code> .   |
| <code>width</code>    | The standardized width for the kernel smoothing. The smoothing uses a value of <code>width*s</code> for epsilon, where <code>s</code> is the bootstrap estimate of the standard error of the statistic of interest. <code>width</code> should take a value in the range (0.2, 1) to produce a reasonable smoothed distribution. If <code>width</code> is too large then the distribution becomes closer to uniform. |

## Details

The new distributional weights are found by applying a normal kernel smoother to the observed values of  $\tau$  weighted by the observed frequencies in the bootstrap simulation. The resulting distribution may not have parameter value exactly equal to the required value `theta` but it will typically have a value which is close to `theta`. The details of how this method works can be found in Davison, Hinkley and Worton (1995) and Section 3.9.2 of Davison and Hinkley (1997).

## Value

If `length(theta)` is 1 then a vector with the same length as the data set `boot.out$data` is returned. The value in position `i` is the probability to be given to the data point in position `i` so that the distribution has parameter value approximately equal to `theta`. If `length(theta)` is bigger than 1 then the returned value is a matrix with `length(theta)` rows each of which corresponds to a distribution with the parameter value approximately equal to the corresponding value of `theta`.

## Examples

```
# Example 9.8 of Davison and Hinkley (1997) requires tilting the resampling
# distribution of the studentized statistic to be centred at the observed
# value of the test statistic 1.84. In the book exponential tilting was used
# but it is also possible to use smooth.f.
grav1 <- gravity[as.numeric(gravity[, 2]) >= 7, ]
grav.fun <- function(dat, w, orig) {
  strata <- tapply(dat[, 2], as.numeric(dat[, 2]))
  d <- dat[, 1]
  ns <- tabulate(strata)
  w <- w/tapply(w, strata, sum)[strata]
  mns <- as.vector(tapply(d * w, strata, sum)) # drop names
  mn2 <- tapply(d * d * w, strata, sum)
  s2hat <- sum(mn2 - mns^2)/ns
  c(mns[2] - mns[1], s2hat, (mns[2]-mns[1]-orig)/sqrt(s2hat))
}
grav.z0 <- grav.fun(grav1, rep(1, 26), 0)
grav.boot <- boot(grav1, grav.fun, R = 499, stype = "w",
  strata = grav1[, 2], orig = grav.z0[1])
grav.sm <- smooth.f(grav.z0[3], grav.boot, index = 3)

# Now we can run another bootstrap using these weights
grav.boot2 <- boot(grav1, grav.fun, R = 499, stype = "w",
  strata = grav1[, 2], orig = grav.z0[1],
  weights = grav.sm)

# Estimated p-values can be found from these as follows
```

```

mean(grav.boot$t[, 3] >= grav.z0[3])
imp.prob(grav.boot2, t0 = -grav.z0[3], t = -grav.boot2$t[, 3])

# Note that for the importance sampling probability we must
# multiply everything by -1 to ensure that we find the correct
# probability. Raw resampling is not reliable for probabilities
# greater than 0.5. Thus
1 - imp.prob(grav.boot2, index = 3, t0 = grav.z0[3])$raw
# can give very strange results (negative probabilities).

```

sunspot

*Annual Mean Sunspot Numbers*

---

### Description

sunspot is a time series and contains 289 observations.

The Zurich sunspot numbers have been analyzed in almost all books on time series analysis as well as numerous papers. The data set, usually attributed to Rudolf Wolf, consists of means of daily relative numbers of sunspot sightings. The relative number for a day is given by  $k(f+10g)$  where  $g$  is the number of sunspot groups observed,  $f$  is the total number of spots within the groups and  $k$  is a scaling factor relating the observer and telescope to a baseline. The relative numbers are then averaged to give an annual figure. See Inzenman (1983) for a discussion of the relative numbers. The figures are for the years 1700-1988.

survival

*Survival of Rats after Radiation Doses*

---

### Description

The survival data frame has 14 rows and 2 columns.

The data measured the survival percentages of batches of rats who were given varying doses of radiation. At each of 6 doses there were two or three replications of the experiment.

### Usage

```
survival
```

**Format**

This data frame contains the following columns:

dose The dose of radiation administered (rads).

surv The survival rate of the batches expressed as a percentage.

**Source**

The data were obtained from

|     |                                 |
|-----|---------------------------------|
| tau | <i>Tau Particle Decay Modes</i> |
|-----|---------------------------------|

---

**Description**

The `tau` data frame has 60 rows and 2 columns.

The tau particle is a heavy electron-like particle discovered in the 1970's by Martin Perl at the Stanford Linear Accelerator Center. Soon after its production the tau particle decays into various collections of more stable particles. About 86% of the time the decay involves just one charged particle. This rate has been measured independently 13 times.

The one-charged-particle event is made up of four major modes of decay as well as a collection of other events. The four main types of decay are denoted rho, pi, e and mu. These rates have been measured independently 6, 7, 14 and 19 times respectively. Due to physical constraints each experiment can only estimate the composite one-charged-particle decay rate or the rate of one of the major modes of decay.

Each experiment consists of a major research project involving many years work. One of the goals of the experiments was to estimate the rate of decay due to events other than the four main modes of decay. These are uncertain events and so cannot themselves be observed directly.

**Usage**

`tau`

**Format**

This data frame contains the following columns:

rate The decay rate expressed as a percentage.

decay The type of decay measured in the experiment. It is a factor with levels 1, rho, pi, e and mu.

Source

The data were obtained from

---

|           |  |
|-----------|--|
| tilt.boot | <i>Non-parametric Tilted Bootstrap</i> |
|-----------|--|

---

Description

This function will run an initial bootstrap with equal resampling probabilities (if required) and will use the output of the initial run to find resampling probabilities which put the value of the statistic at required values. It then runs an importance resampling bootstrap using the calculated probabilities as the resampling distribution.

Usage

```
tilt.boot(data, statistic, R, sim = "ordinary", stype = "i",
          strata = rep(1, n), L = NULL, theta = NULL,
          alpha = c(0.025, 0.975), tilt = TRUE, width = 0.5,
          index = 1, ...)
```

Arguments

|           |  |
|-----------|--|
| data      | The data as a vector, matrix or data frame. If it is a matrix or data frame then each row is considered as one (multivariate) observation.   |
| statistic | A function which when applied to data returns a vector containing the statistic(s) of interest. It must take at least two arguments. The first argument will always be data and the second should be a vector of indices, weights or frequencies describing the bootstrap sample. Any other arguments must be supplied to tilt.boot and will be passed unchanged to statistic each time it is called.  |
| R         | The number of bootstrap replicates required. This will generally be a vector, the first value stating how many uniform bootstrap simulations are to be performed at the initial stage. The remaining values of R are the number of simulations to be performed resampling from each reweighted distribution. The first value of R must always be present, a value of 0 implying that no uniform resampling is to be carried out. Thus length(R) should always equal 1+length(theta). |
| sim       | This is a character string indicating the type of bootstrap simulation required. There are only two possible values that this can take: "ordinary" and "balanced". If other simulation types are required for the initial un-weighted bootstrap then it will be necessary to run boot, calculate the weights appropriately, and run boot again using the calculated weights.   |

|        |   |
|--------|---|
| stype  | A character string indicating the type of second argument expected by <code>statistic</code> . The possible values that <code>stype</code> can take are "i" (indices), "w" (weights) and "f" (frequencies).   |
| strata | An integer vector or factor representing the strata for multi-sample problems.  |
| L      | The empirical influence values for the statistic of interest. They are used only for exponential tilting when <code>tilt</code> is TRUE. If <code>tilt</code> is TRUE and they are not supplied then <code>tilt.boot</code> uses <code>empinf</code> to calculate them.   |
| theta  | The required parameter value(s) for the tilted distribution(s). There should be one value of <code>theta</code> for each of the non-uniform distributions. If <code>R[1]</code> is 0 <code>theta</code> is a required argument. Otherwise <code>theta</code> values can be estimated from the initial uniform bootstrap and the values in <code>alpha</code> .  |
| alpha  | The alpha level to which tilting is required. This parameter is ignored if <code>R[1]</code> is 0 or if <code>theta</code> is supplied, otherwise it is used to find the values of <code>theta</code> as quantiles of the initial uniform bootstrap. In this case <code>R[1]</code> should be large enough that $\min(c(\alpha, 1-\alpha)) * R[1] > 5$ , if this is not the case then a warning is generated to the effect that the <code>theta</code> are extreme values and so the tilted output may be unreliable. |
| tilt   | A logical variable which if TRUE (the default) indicates that exponential tilting should be used, otherwise local frequency smoothing ( <code>smooth.f</code> ) is used. If <code>tilt</code> is FALSE then <code>R[1]</code> must be positive. In fact in this case the value of <code>R[1]</code> should be fairly large (in the region of 500 or more).  |
| width  | This argument is used only if <code>tilt</code> is FALSE, in which case it is passed unchanged to <code>smooth.f</code> as the standardized bandwidth for the smoothing operation. The value should generally be in the range (0.2, 1). See <code>smooth.f</code> for more details.   |
| index  | The index of the statistic of interest in the output from <code>statistic</code> . By default the first element of the output of <code>statistic</code> is used.  |
| ...    | Any additional arguments required by <code>statistic</code> . These are passed unchanged to <code>statistic</code> each time it is called.  |

## Value

An object of class "boot" with the following components

|           |  |
|-----------|--|
| t0        | The observed value of the statistic on the original data.  |
| t         | The values of the bootstrap replicates of the statistic. There will be <code>sum(R)</code> of these, the first <code>R[1]</code> corresponding to the uniform bootstrap and the remainder to the tilted bootstrap(s).  |
| R         | The input vector of the number of bootstrap replicates.  |
| data      | The original data as supplied.   |
| statistic | The <code>statistic</code> function as supplied.   |
| sim       | The simulation type used in the bootstrap(s), it can either be "ordinary" or "balanced".   |
| stype     | The type of statistic supplied, it is the same as the input value <code>stype</code> .   |
| call      | A copy of the original call to <code>tilt.boot</code> .  |
| strata    | The strata as supplied.  |
| weights   | The matrix of weights used. If <code>R[1]</code> is greater than 0 then the first row will be the uniform weights and each subsequent row the tilted weights. If <code>R[1]</code> equals 0 then the uniform weights are omitted and only the tilted weights are output. |

`theta`                    The values of `theta` used for the tilted distributions. These are either the input values or the values derived from the uniform bootstrap and `alpha`.

          strata = grav1[,2], tilt = TRUE, index = 3, orig = grav.z0[1])

# Example 9.10 of Davison and Hinkley (1997) requires a balanced
# importance resampling bootstrap to be run. In this example we
# show how this might be run.
acme.fun <- function(data, i, bhat) {
  d <- data[i,]
  n <- nrow(d)
  d.lm <- glm(d$acme~d$market)
  beta.b <- coef(d.lm)[2]
  d.diag <- boot::glm.diag(d.lm)
  SSx <- (n-1)*var(d$market)
  tmp <- (d$market-mean(d$market))*d.diag$res*d.diag$sd
  sr <- sqrt(sum(tmp^2))/SSx
  c(beta.b, sr, (beta.b-bhat)/sr)
}
acme.b <- acme.fun(acme, 1:nrow(acme), 0)
acme.boot1 <- tilt.boot(acme, acme.fun, R = c(499, 250, 250),
                      stype = "i", sim = "balanced", alpha = c(0.05, 0.95),
                      tilt = TRUE, index = 3, bhat = acme.b[1])
```

**Description**

Generate R bootstrap replicates of a statistic applied to a time series. The replicate time series can be generated using fixed or random block lengths or can be model based replicates.

**Usage**

```
tsboot(tseries, statistic, R, l = NULL, sim = "model",
       endcorr = TRUE, n.sim = NROW(tseries), orig.t = TRUE,
       ran.gen, ran.args = NULL, norm = TRUE, ...,
       parallel = c("no", "multicore", "snow"),
       ncpus = getOption("boot.ncpus", 1L), cl = NULL)
```

**Arguments**

|                        |   |
|------------------------|---|
| <code>tseries</code>   | A univariate or multivariate time series.   |
| <code>statistic</code> | A function which when applied to <code>tseries</code> returns a vector containing the statistic(s) of interest. Each time <code>statistic</code> is called it is passed a time series of length <code>n.sim</code> which is of the same class as the original <code>tseries</code> . Any other arguments which <code>statistic</code> takes must remain constant for each bootstrap replicate and should be supplied through the <code>...</code> argument to <code>tsboot</code> .                       |
| <code>R</code>         | A positive integer giving the number of bootstrap replicates required.  |
| <code>sim</code>       | The type of simulation required to generate the replicate time series. The possible input values are "model" (model based resampling), "fixed" (block resampling with fixed block lengths of 1), "geom" (block resampling with block lengths having a geometric distribution with mean 1) or "scramble" (phase scrambling).   |
| <code>l</code>         | If <code>sim</code> is "fixed" then <code>l</code> is the fixed block length used in generating the replicate time series. If <code>sim</code> is "geom" then <code>l</code> is the mean of the geometric distribution used to generate the block lengths. <code>l</code> should be a positive integer less than the length of <code>tseries</code> . This argument is not required when <code>sim</code> is "model" but it is required for all other simulation types.                                   |
| <code>endcorr</code>   | A logical variable indicating whether end corrections are to be applied when <code>sim</code> is "fixed". When <code>sim</code> is "geom", <code>endcorr</code> is automatically set to TRUE; <code>endcorr</code> is not used when <code>sim</code> is "model" or "scramble".  |
| <code>n.sim</code>     | The length of the simulated time series. Typically this will be equal to the length of the original time series but there are situations when it will be larger. One obvious situation is if prediction is required. Another situation in which <code>n.sim</code> is larger than the original length is if <code>tseries</code> is a residual time series from fitting some model to the original time series. In this case, <code>n.sim</code> would usually be the length of the original time series. |
| <code>orig.t</code>    | A logical variable which indicates whether <code>statistic</code> should be applied to <code>tseries</code> itself as well as the bootstrap replicate series. If <code>statistic</code> is expecting a longer time series than <code>tseries</code> or if applying <code>statistic</code> to <code>tseries</code> will not yield any useful information then <code>orig.t</code> should be set to FALSE.  |

|                                  |   |
|----------------------------------|---|
| <code>ran.gen</code>             | This is a function of three arguments. The first argument is a time series. If <code>sim</code> is "model" then it will always be <code>tseries</code> that is passed. For other simulation types it is the result of selecting <code>n.sim</code> observations from <code>tseries</code> by some scheme and converting the result back into a time series of the same form as <code>tseries</code> (although of length <code>n.sim</code> ). The second argument to <code>ran.gen</code> is always the value <code>n.sim</code> , and the third argument is <code>ran.args</code> , which is used to supply any other objects needed by <code>ran.gen</code> . If <code>sim</code> is "model" then the generation of the replicate time series will be done in <code>ran.gen</code> (for example through use of <code>arima.sim</code> ). For the other simulation types <code>ran.gen</code> is used for 'post-blackening'. The default is that the function simply returns the time series passed to it. |
| <code>ran.args</code>            | This will be supplied to <code>ran.gen</code> each time it is called. If <code>ran.gen</code> needs any extra arguments then they should be supplied as components of <code>ran.args</code> . Multiple arguments may be passed by making <code>ran.args</code> a list. If <code>ran.args</code> is <code>NULL</code> then it should not be used within <code>ran.gen</code> but note that <code>ran.gen</code> must still have its third argument.  |
| <code>norm</code>                | A logical argument indicating whether normal margins should be used for phase scrambling. If <code>norm</code> is <code>FALSE</code> then margins corresponding to the exact empirical margins are used.  |
| <code>...</code>                 | Extra named arguments to <code>statistic</code> may be supplied here. Beware of partial matching to the arguments of <code>tsboot</code> listed above.  |
| <code>parallel, ncpus, cl</code> | See the help for <code>boot</code> .  |

## Details

If `sim` is "fixed" then each replicate time series is found by taking blocks of length `l`, from the original time series and putting them end-to-end until a new series of length `n.sim` is created. When `sim` is "geom" a similar approach is taken except that now the block lengths are generated from a geometric distribution with mean 1. Post-blackening can be carried out on these replicate time series by including the function `ran.gen` in the call to `tsboot` and having `tseries` as a time series of residuals.

Model based resampling is very similar to the parametric bootstrap and all simulation must be in one of the user specified functions. This avoids the complicated problem of choosing the block length but relies on an accurate model choice being made.

Phase scrambling is described in Section 8.2.4 of Davison and Hinkley (1997). The types of statistic for which this method produces reasonable results is very limited and the other methods seem to do better in most situations. Other types of resampling in the frequency domain can be accomplished using the function `boot` with the argument `sim = "parametric"`.

## Value

An object of class "boot" with the following components.

|                        |  |
|------------------------|--|
| <code>t0</code>        | If <code>orig.t</code> is <code>TRUE</code> then <code>t0</code> is the result of <code>statistic(tseries, ...{})</code> otherwise it is <code>NULL</code> . |
| <code>t</code>         | The results of applying <code>statistic</code> to the replicate time series.   |
| <code>R</code>         | The value of <code>R</code> as supplied to <code>tsboot</code> .   |
| <code>tseries</code>   | The original time series.  |
| <code>statistic</code> | The function <code>statistic</code> as supplied.   |

|                       |  |
|-----------------------|--|
| <code>sim</code>      | The simulation type used in generating the replicates.   |
| <code>endcorr</code>  | The value of <code>endcorr</code> used. The value is meaningful only when <code>sim</code> is "fixed"; it is ignored for model based simulation or phase scrambling and is always set to TRUE if <code>sim</code> is "geom". |
| <code>n.sim</code>    | The value of <code>n.sim</code> used.  |
| <code>l</code>        | The value of <code>l</code> used for block based resampling. This will be NULL if block based resampling was not used.   |
| <code>ran.gen</code>  | The <code>ran.gen</code> function used for generating the series or for 'post-blackening'.   |
| <code>ran.args</code> | The extra arguments passed to <code>ran.gen</code> .   |
| <code>call</code>     | The original call to <code>tsboot</code> .   |

## Examples

```
lynx.fun <- function(tsb) {
  ar.fit <- ar(tsb, order.max = 25)
  c(ar.fit$order, mean(tsb), tsb)
}

# the stationary bootstrap with mean block length 20
lynx.1 <- tsboot(log(lynx), lynx.fun, R = 99, l = 20, sim = "geom")

# the fixed block bootstrap with length 20
lynx.2 <- tsboot(log(lynx), lynx.fun, R = 99, l = 20, sim = "fixed")

# Now for model based resampling we need the original model
# Note that for all of the bootstraps which use the residuals as their
# data, we set orig.t to FALSE since the function applied to the residual
# time series will be meaningless.
lynx.ar <- ar(log(lynx))
lynx.model <- list(order = c(lynx.ar$order, 0, 0), ar = lynx.ar$ar)
lynx.res <- lynx.ar$resid[!is.na(lynx.ar$resid)]
lynx.res <- lynx.res - mean(lynx.res)

lynx.sim <- function(res, n.sim, ran.args) {
  # random generation of replicate series using arima.sim
  rgl <- function(n, res) sample(res, n, replace = TRUE)
  ts.orig <- ran.args$ts
  ts.mod <- ran.args$model
  mean(ts.orig) + ts(arima.sim(model = ts.mod, n = n.sim,
    rand.gen = rgl, res = as.vector(res)))
}
```

```

}

lynx.3 <- tsboot(lynx.res, lynx.fun, R = 99, sim = "model", n.sim = 114,
               orig.t = FALSE, ran.gen = lynx.sim,
               ran.args = list(ts = log(lynx), model = lynx.model))

# For "post-blackening" we need to define another function
lynx.black <- function(res, n.sim, ran.args) {
  ts.orig <- ran.args$ts
  ts.mod <- ran.args$model
  mean(ts.orig) + ts(arima.sim(model = ts.mod, n = n.sim, innov = res))
}

# Now we can run apply the two types of block resampling again but this
# time applying post-blackening.
lynx.1b <- tsboot(lynx.res, lynx.fun, R = 99, l = 20, sim = "fixed",
                 n.sim = 114, orig.t = FALSE, ran.gen = lynx.black,
                 ran.args = list(ts = log(lynx), model = lynx.model))

lynx.2b <- tsboot(lynx.res, lynx.fun, R = 99, l = 20, sim = "geom",
                 n.sim = 114, orig.t = FALSE, ran.gen = lynx.black,
                 ran.args = list(ts = log(lynx), model = lynx.model))

# To compare the observed order of the bootstrap replicates we
# proceed as follows.
table(lynx.1$t[, 1])
table(lynx.1b$t[, 1])
table(lynx.2$t[, 1])
table(lynx.2b$t[, 1])
table(lynx.3$t[, 1])
# Notice that the post-blackened and model-based bootstraps preserve
# the true order of the model (11) in many more cases than the others.

```

---

tuna

*Tuna Sighting Data*

---

## Description

The tuna data frame has 64 rows and 1 columns.

The data come from an aerial line transect survey of Southern Bluefin Tuna in the Great Australian Bight. An aircraft with two spotters on board flies randomly allocated line transects. Each school of tuna sighted is counted and its perpendicular distance from the transect measured. The survey was conducted in summer when tuna tend to stay on the surface.

## Usage

```
tuna
```

## Format

This data frame contains the following column:

- y The perpendicular distance, in miles, from the transect for 64 independent sightings of tuna schools.

**Source**

The data were obtained from

Chen, S.X. (1996) Empirical likelihood confidence intervals for nonparametric density estimation. *Biometrika*, **83**, 329–341.

---

urine

*Urine Analysis Data*

---

**Description**

The `urine` data frame has 79 rows and 7 columns.

79 urine specimens were analyzed in an effort to determine if certain physical characteristics of the urine might be related to the formation of calcium oxalate crystals.

**Usage**

```
urine
```

**Format**

This data frame contains the following columns:

`r` Indicator of the presence of calcium oxalate crystals.

`gravity` The specific gravity of the urine.

`ph` The pH reading of the urine.

`osmo` The osmolarity of the urine. Osmolarity is proportional to the concentration of molecules in solution.

`cond` The conductivity of the urine. Conductivity is proportional to the concentration of charged ions in solution.

`urea` The urea concentration in millimoles per litre.

`calc` The calcium concentration in millimoles per litre.

**Source**

The data were obtained from

|-------------------------|---------------------------------|
| <code>var.linear</code> | <i>Linear Variance Estimate</i> |
|-------------------------|---------------------------------|

---

### Description

Estimates the variance of a statistic from its empirical influence values.

### Usage

```
var.linear(L, strata = NULL)
```

### Arguments

|                     |  |
|---------------------|--|
| <code>L</code>      | Vector of the empirical influence values of a statistic. These will usually be calculated by a call to <code>empinf</code> . |
| <code>strata</code> | A numeric vector or factor specifying which observations (and hence empirical influence values) come from which strata.      |

### Value

The variance estimate calculated from `L`.

### Examples

```
# To estimate the variance of the ratio of means for the city data.
ratio <- function(d,w) sum(d$x * w)/sum(d$u * w)
var.linear(empinf(data = city, statistic = ratio))
```

---

|                   |  |
|-------------------|--|
| <code>wool</code> | <i>Australian Relative Wool Prices</i> |
|-------------------|--|

---

### Description

`wool` is a time series of class "ts" and contains 309 observations.

Each week that the market is open the Australian Wool Corporation set a floor price which determines their policy on intervention and is therefore a reflection of the overall price of wool for the week in question. Actual prices paid can vary considerably about the floor price. The series here is the log of the ratio between the price for fine grade wool and the floor price, each market week between July 1976 and Jun 1984.

### Source

The data were obtained from

Diggle, P.J. (1990) *Time Series: A Biostatistical Introduction*. Oxford University Press.

## Chapter 19

# The `class` package

---

`batchSOM`

*Self-Organizing Maps: Batch Algorithm*

---

### Description

Kohonen's Self-Organizing Maps are a crude form of multidimensional scaling.

### Usage

```
batchSOM(data, grid = somgrid(), radii, init)
```

### Arguments

|                    |   |
|--------------------|---|
| <code>data</code>  | a matrix or data frame of observations, scaled so that Euclidean distance is appropriate.                         |
| <code>grid</code>  | A grid for the representatives: see <a href="#">somgrid</a> .   |
| <code>radii</code> | the radii of the neighbourhood to be used for each pass: one pass is run for each element of <code>radii</code> . |
| <code>init</code>  | the initial representatives. If missing, chosen (without replacement) randomly from <code>data</code> .           |

### Details

The batch SOM algorithm of Kohonen(1995, section 3.14) is used.

### Value

An object of class "`SOM`" with components

|                    |  |
|--------------------|--|
| <code>grid</code>  | the grid, an object of class " <code>somgrid</code> ". |
| <code>codes</code> | a matrix of representatives.                           |

gr <- somgrid(topo = "hexagonal")
crabs.som <- batchSOM(lcrabs, gr, c(4, 4, 2, 2, 1, 1, 1, 0, 0))
plot(crabs.som)

bins <- as.numeric(knn1(crabs.som$codes, lcrabs, 0:47))
plot(crabs.som$grid, type = "n")
symbols(crabs.som$grid$pts[, 1], crabs.som$grid$pts[, 2],
        circles = rep(0.4, 48), inches = FALSE, add = TRUE)
text(crabs.som$grid$pts[bins, ] + rnorm(400, 0, 0.1),
     as.character(crabs.grp))
```

---

condense

---

*Condense training set for k-NN classifier*

---

**Description**

Condense training set for k-NN classifier

**Usage**

```
condense(train, class, store, trace = TRUE)
```

**Arguments**

|                    |  |
|--------------------|--|
| <code>train</code> | matrix for training set  |
| <code>class</code> | vector of classifications for test set                             |
| <code>store</code> | initial store set. Default one randomly chosen element of the set. |
| <code>trace</code> | logical. Trace iterations?   |

**Details**

The store set is used to 1-NN classify the rest, and misclassified patterns are added to the store set. The whole set is checked until no additions occur.

**Value**

Index vector of cases to be retained (the final store set).

```

---

|     |  |
|-----|--|
| knn | <i>k</i> -Nearest Neighbour Classification |
|-----|--|

---

## Description

*k*-nearest neighbour classification for test set from training set. For each row of the test set, the *k* nearest (in Euclidean distance) training set vectors are found, and the classification is decided by majority vote, with ties broken at random. If there are ties for the *k*th nearest vector, all candidates are included in the vote.

## Usage

```
knn(train, test, cl, k = 1, l = 0, prob = FALSE, use.all = TRUE)
```

## Arguments

|                      |   |
|----------------------|---|
| <code>train</code>   | matrix or data frame of training set cases.   |
| <code>test</code>    | matrix or data frame of test set cases. A vector will be interpreted as a row vector for a single case.   |
| <code>cl</code>      | factor of true classifications of training set  |
| <code>k</code>       | number of neighbours considered.  |
| <code>l</code>       | minimum vote for definite decision, otherwise <code>doubt</code> . (More precisely, less than <i>k</i> –1 dissenting votes are allowed, even if <i>k</i> is increased by ties.)                                   |
| <code>prob</code>    | If this is true, the proportion of the votes for the winning class are returned as attribute <code>prob</code> .  |
| <code>use.all</code> | controls handling of ties. If true, all distances equal to the <i>k</i> th largest are included. If false, a random selection of distances equal to the <i>k</i> th is chosen to use exactly <i>k</i> neighbours. |

**Value**

Factor of classifications of test set. `doubt` will be returned as NA.

**References**

Ripley, B. D. (1996) *Pattern Recognition and Neural Networks*. Cambridge.

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

cl    <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
knn(train, test, cl, k = 3, prob=TRUE)
attributes(.Last.value)
```

---

knn.cv

*k-Nearest Neighbour Cross-Validatory Classification*

---

**Description**

k-nearest neighbour cross-validatory classification from training set.

**Usage**

```
knn.cv(train, cl, k = 1, l = 0, prob = FALSE, use.all = TRUE)
```

**Arguments**

|                      |  |
|----------------------|--|
| <code>train</code>   | matrix or data frame of training set cases.  |
| <code>cl</code>      | factor of true classifications of training set   |
| <code>k</code>       | number of neighbours considered.   |
| <code>l</code>       | minimum vote for definite decision, otherwise <code>doubt</code> . (More precisely, less than $k-1$ dissenting votes are allowed, even if $k$ is increased by ties.)                               |
| <code>prob</code>    | If this is true, the proportion of the votes for the winning class are returned as attribute <code>prob</code> .   |
| <code>use.all</code> | controls handling of ties. If true, all distances equal to the $k$ th largest are included. If false, a random selection of distances equal to the $k$ th is chosen to use exactly $k$ neighbours. |

**Details**

This uses leave-one-out cross validation. For each row of the training set `train`, the  $k$  nearest (in Euclidean distance) other training set vectors are found, and the classification is decided by majority vote, with ties broken at random. If there are ties for the  $k$ th nearest vector, all candidates are included in the vote.

**Value**

Factor of classifications of training set. `doubt` will be returned as NA.

train <- rbind(iris3[1:25,,1], iris3[1:25,,2], iris3[1:25,,3])
test  <- rbind(iris3[26:50,,1], iris3[26:50,,2], iris3[26:50,,3])
cl    <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
cd    <- lvqinit(train, cl, 10)
lvqtest(cd, train)
cd0   <- olvq1(train, cl, cd)
lvqtest(cd0, train)
cd2   <- lvq2(train, cl, cd0)
lvqtest(cd2, train)
```

---

lvq3

*Learning Vector Quantization 3*

---

**Description**

Moves examples in a codebook to better represent the training set.

**Usage**

```
lvq3(x, cl, codebk, niter = 100*nrow(codebk$x), alpha = 0.03,
     win = 0.3, epsilon = 0.1)
```

**Arguments**

|                      |   |
|----------------------|---|
| <code>x</code>       | a matrix or data frame of examples                        |
| <code>cl</code>      | a vector or factor of classifications for the examples    |
| <code>codebk</code>  | a codebook  |
| <code>niter</code>   | number of iterations                                      |
| <code>alpha</code>   | constant for training                                     |
| <code>win</code>     | a tolerance for the closeness of the two nearest vectors. |
| <code>epsilon</code> | proportion of move for correct vectors                    |

**Details**

Selects `niter` examples at random with replacement, and adjusts the nearest two examples in the codebook for each.

**Value**

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

|---------|----------------------------------|
| lvqinit | <i>Initialize a LVQ Codebook</i> |
|---------|----------------------------------|

---

## Description

Construct an initial codebook for LVQ methods.

## Usage

```
lvqinit(x, cl, size, prior, k = 5)
```

## Arguments

- |                    |   |
|--------------------|---|
| <code>x</code>     | a matrix or data frame of training examples, $n$ by $p$ .   |
| <code>cl</code>    | the classifications for the training examples. A vector or factor of length $n$ .   |
| <code>size</code>  | the size of the codebook. Defaults to $\min(\text{round}(0.4 \cdot ng \cdot (ng - 1 + p/2)), 0), n)$ where $ng$ is the number of classes. |
| <code>prior</code> | Probabilities to represent classes in the codebook. Default proportions in the training set.  |
| <code>k</code>     | $k$ used for $k$ -NN test of correct classification. Default is 5.  |

## Details

Selects `size` examples from the training set without replacement with proportions proportional to the prior or the original proportions.

## Value

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

|---------|--|

---

Description

Classify a test set by 1-NN from a specified LVQ codebook.

Usage

```
lvqtest(codebk, test)
```

Arguments

|        |  |
|--------|--|
| codebk | codebook object returned by other LVQ software |
| test   | matrix of test examples                        |

Details

Uses 1-NN to classify each test example against the codebook.

Value

Factor of classification for each row of x

reduce.nn

*Reduce Training Set for a k-NN Classifier*

---

**Description**

Reduce training set for a k-NN classifier. Used after `condense`.

**Usage**

```
reduce.nn(train, ind, class)
```

**Arguments**

|                    |  |
|--------------------|--|
| <code>train</code> | matrix for training set  |
| <code>ind</code>   | Initial list of members of the training set (from <code>condense</code> ). |
| <code>class</code> | vector of classifications for test set                                     |

**Details**

All the members of the training set are tried in random order. Any which when dropped do not cause any members of the training set to be wrongly classified are dropped.

**Value**

Index vector of cases to be retained.

SOM

*Self-Organizing Maps: Online Algorithm*

## Description

Kohonen's Self-Organizing Maps are a crude form of multidimensional scaling.

## Usage

```
SOM(data, grid = somgrid(), rlen = 10000, alpha, radii, init)
```

## Arguments

|                    |   |
|--------------------|---|
| <code>data</code>  | a matrix or data frame of observations, scaled so that Euclidean distance is appropriate.   |
| <code>grid</code>  | A grid for the representatives: see <a href="#">somgrid</a> .   |
| <code>rlen</code>  | the number of updates: used only in the defaults for <code>alpha</code> and <code>radii</code> .  |
| <code>alpha</code> | the amount of change: one update is done for each element of <code>alpha</code> . Default is to decline linearly from 0.05 to 0 over <code>rlen</code> updates.                       |
| <code>radii</code> | the radii of the neighbourhood to be used for each update: must be the same length as <code>alpha</code> . Default is to decline linearly from 4 to 1 over <code>rlen</code> updates. |
| <code>init</code>  | the initial representatives. If missing, chosen (without replacement) randomly from <code>data</code> .   |

## Details

`alpha` and `radii` can also be lists, in which case each component is used in turn, allowing two- or more phase training.

## Value

An object of class "SOM" with components

|                    |   |
|--------------------|---|
| <code>grid</code>  | the grid, an object of class "somgrid". |
| <code>codes</code> | a matrix of representatives.            |

## Examples

```
require(graphics)
data(crabs, package = "MASS")

lcrabs <- log(crabs[, 4:8])
crabs.grp <- factor(c("B", "b", "O", "o")[rep(1:4, rep(50,4))])
gr <- somgrid(topo = "hexagonal")
crabs.som <- SOM(lcrabs, gr)
plot(crabs.som)

## 2-phase training
crabs.som2 <- SOM(lcrabs, gr,
  alpha = list(seq(0.05, 0, length.out = 1e4), seq(0.02, 0, length.out = 1e5)),
  radii = list(seq(8, 1, length.out = 1e4), seq(4, 1, length.out = 1e5)))
plot(crabs.som2)
```

---

somgrid

*Plot SOM Fits*

---

## Description

Plotting functions for SOM results.

## Usage

```
somgrid(xdim = 8, ydim = 6, topo = c("rectangular", "hexagonal"))

## S3 method for class 'somgrid'
plot(x, type = "p", ...)

## S3 method for class 'SOM'
plot(x, ...)
```

## Arguments

|            |   |
|------------|---|
| xdim, ydim | dimensions of the grid                              |
| topo       | the topology of the grid.                           |
| x          | an object inheriting from class "somgrid" or "SOM". |
| type, ...  | graphical parameters.                               |

**Details**

The class "somgrid" records the coordinates of the grid to be used for (batch or on-line) SOM: this has a plot method.

The plot method for class "SOM" plots a [stars](#) plot of the representative at each grid point.

**Value**

For somgrid, an object of class "somgrid", a list with components

|                  |   |
|------------------|---|
| pts              | a two-column matrix giving locations for the grid points. |
| xdim, ydim, topo | as in the arguments to somgrid.                           |

## Chapter 20

# The `cluster` package

---

`agnes`

*Agglomerative Nesting (Hierarchical Clustering)*

---

### Description

Computes agglomerative hierarchical clustering of the dataset.

### Usage

```
agnes(x, diss = inherits(x, "dist"), metric = "euclidean",
      stand = FALSE, method = "average", par.method,
      keep.diss = n < 100, keep.data = !diss, trace.lev = 0)
```

### Arguments

|                     |   |
|---------------------|---|
| <code>x</code>      | <p>data matrix or data frame, or dissimilarity matrix, depending on the value of the <code>diss</code> argument.</p> <p>In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.</p> <p>In case of a dissimilarity matrix, <code>x</code> is typically the output of <code>daisy</code> or <code>dist</code>. Also a vector with length <math>n*(n-1)/2</math> is allowed (where <math>n</math> is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.</p> |
| <code>diss</code>   | <p>logical flag: if TRUE (default for <code>dist</code> or <code>dissimilarity</code> objects), then <code>x</code> is assumed to be a dissimilarity matrix. If FALSE, then <code>x</code> is treated as a matrix of observations by variables.</p>   |
| <code>metric</code> | <p>character string specifying the metric to be used for calculating dissimilarities between observations. The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.</p>   |
| <code>stand</code>  | <p>logical flag: if TRUE, then the measurements in <code>x</code> are standardized before calculating the dissimilarities. Measurements are standardized for each variable</p>  |

|                                   |  |
|-----------------------------------|--|
|                                   | (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation. If $x$ is already a dissimilarity matrix, then this argument will be ignored.   |
| <code>method</code>               | character string defining the clustering method. The six methods implemented are "average" (unweighted pair-group [arithMetic] average method, aka 'UPGMA'), "single" (single linkage), "complete" (complete linkage), "ward" (Ward's method), "weighted" (weighted average linkage, aka 'WPGMA'), its generalization "flexible" which uses (a constant version of) the Lance-Williams formula and the <code>par.method</code> argument, and "gaverage" a generalized "average" aka "flexible UPGMA" method also using the Lance-Williams formula and <code>par.method</code> .<br>The default is "average". |
| <code>par.method</code>           | If <code>method</code> is "flexible" or "gaverage", a numeric vector of length 1, 3, or 4, (with a default for "gaverage"), see in the details section.  |
| <code>keep.diss, keep.data</code> | logicals indicating if the dissimilarities and/or input data $x$ should be kept in the result. Setting these to FALSE can give much smaller results and hence even save memory allocation <i>time</i> .  |
| <code>trace.lev</code>            | integer specifying a trace level for printing diagnostics during the algorithm. Default 0 does not print anything; higher values print increasingly more.  |

## Details

`agnes` is fully described in chapter 5 of Kaufman and Rousseeuw (1990). Compared to other agglomerative clustering methods such as `hclust`, `agnes` has the following features: (a) it yields the agglomerative coefficient (see `agnes.object`) which measures the amount of clustering structure found; and (b) apart from the usual tree it also provides the banner, a novel graphical display (see `plot.agnes`).

The `agnes`-algorithm constructs a hierarchy of clusterings.

At first, each observation is a small cluster by itself. Clusters are merged until only one large cluster remains which contains all the observations. At each stage the two *nearest* clusters are combined to form one larger cluster.

For `method="average"`, the distance between two clusters is the average of the dissimilarities between the points in one cluster and the points in the other cluster.

In `method="single"`, we use the smallest dissimilarity between a point in the first cluster and a point in the second cluster (nearest neighbor method).

When `method="complete"`, we use the largest dissimilarity between a point in the first cluster and a point in the second cluster (furthest neighbor method).

The `method="flexible"` allows (and requires) more details: The Lance-Williams formula specifies how dissimilarities are computed when clusters are agglomerated (equation (32) in K&R(1990), p.237). If clusters  $C_1$  and  $C_2$  are agglomerated into a new cluster, the dissimilarity between their union and another cluster  $Q$  is given by

$$D(C_1 \cup C_2, Q) = \alpha_1 * D(C_1, Q) + \alpha_2 * D(C_2, Q) + \beta * D(C_1, C_2) + \gamma * |D(C_1, Q) - D(C_2, Q)|,$$

where the four coefficients  $(\alpha_1, \alpha_2, \beta, \gamma)$  are specified by the vector `par.method`, either directly as vector of length 4, or (more conveniently) if `par.method` is of length 1, say  $= \alpha$ , `par.method` is extended to give the "Flexible Strategy" (K&R(1990), p.236 f) with Lance-Williams coefficients  $(\alpha_1 = \alpha_2 = \alpha, \beta = 1 - 2\alpha, \gamma = 0)$ .

Also, if `length(par.method) == 3`,  $\gamma = 0$  is set.

**Care** and expertise is probably needed when using `method = "flexible"` particularly for the case when `par.method` is specified of longer length than one. Since **cluster** version 2.0, choices leading to invalid merge structures now signal an error (from the C code already). The *weighted average* (`method="weighted"`) is the same as `method="flexible", par.method = 0.5`. Further, `method = "single"` is equivalent to `method="flexible", par.method = c(.5, .5, 0, -.5)`, and `method="complete"` is equivalent to `method="flexible", par.method = c(.5, .5, 0, +.5)`.

The `method = "gaverage"` is a generalization of "average", aka "flexible UPGMA" method, and is (a generalization of the approach) detailed in Belbin et al. (1992). As "flexible", it uses the Lance-Williams formula above for dissimilarity updating, but with  $\alpha_1$  and  $\alpha_2$  not constant, but *proportional* to the sizes  $n_1$  and  $n_2$  of the clusters  $C_1$  and  $C_2$  respectively, i.e.,

$$\alpha_j = \alpha'_j \frac{n_1}{n_1 + n_2},$$

where  $\alpha'_1, \alpha'_2$  are determined from `par.method`, either directly as  $(\alpha_1, \alpha_2, \beta, \gamma)$  or  $(\alpha_1, \alpha_2, \beta)$  with  $\gamma = 0$ , or (less flexibly, but more conveniently) as follows:

Belbin et al proposed "flexible beta", i.e. the user would only specify  $\beta$  (as `par.method`), sensibly in

$$-1 \leq \beta < 1,$$

and  $\beta$  determines  $\alpha'_1$  and  $\alpha'_2$  as

$$\alpha'_j = 1 - \beta,$$

and  $\gamma = 0$ .

This  $\beta$  may be specified by `par.method` (as length 1 vector), and if `par.method` is not specified, a default value of -0.1 is used, as Belbin et al recommend taking a  $\beta$  value around -0.1 as a general agglomerative hierarchical clustering strategy.

Note that `method = "gaverage", par.method = 0` (or `par.method = c(1, 1, 0, 0)`) is equivalent to the `agnes()` default method "average".

## Value

an object of class "agnes" (which extends "twins") representing the clustering. See [agnes.object](#) for details, and methods applicable.

## BACKGROUND

Cluster analysis divides a dataset into groups (clusters) of observations that are similar to each other.

**Hierarchical methods** like `agnes`, `diana`, and `mona` construct a hierarchy of clusterings, with the number of clusters ranging from one to the number of observations.

**Partitioning methods** like `pam`, `clara`, and `fanny` require that the number of clusters be given by the user.

## Author(s)

Method "gaverage" has been contributed by Pierre Roudier, Landcare Research, New Zealand.

```

---

agnes.object

*Agglomerative Nesting (AGNES) Object*

---

## Description

The objects of class "agnes" represent an agglomerative hierarchical clustering of a dataset.

## Value

A legitimate agnes object is a list with the following components:

|           |   |
|-----------|---|
| order     | a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.   |
| order.lab | a vector similar to order, but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled.   |
| height    | a vector with the distances between merging clusters at the successive stages.  |
| ac        | the agglomerative coefficient, measuring the clustering structure of the dataset. For each observation $i$ , denote by $m(i)$ its dissimilarity to the first cluster it is merged with, divided by the dissimilarity of the merger in the final step of the algorithm. The <code>ac</code> is the average of all $1 - m(i)$ . It can also be seen as the average width (or the percentage filled) of the banner plot. Because <code>ac</code> grows with the number of observations, this measure should not be used to compare datasets of very different sizes. |
| merge     | an $(n-1)$ by 2 matrix, where $n$ is the number of observations. Row $i$ of <code>merge</code> describes the merging of clusters at step $i$ of the clustering. If a number $j$ in the row is negative, then the single observation $ j $ is merged at this stage. If $j$ is positive, then the merger is with the cluster formed at stage $j$ of the algorithm.  |
| diss      | an object of class "dissimilarity" (see <a href="#">dissimilarity.object</a> ), representing the total dissimilarity matrix of the dataset.   |
| data      | a matrix containing the original or standardized measurements, depending on the <code>stand</code> option of the function <code>agnes</code> . If a dissimilarity matrix was given as input structure, then this component is not available.  |

GENERATION

This class of objects is returned from `agnes`.

METHODS

The "agnes" class has methods for the following generic functions: `print`, `summary`, `plot`, and `as.dendrogram`.  
In addition, `cutree(x, *)` can be used to “cut” the dendrogram in order to produce cluster assignments.

INHERITANCE

The class "agnes" inherits from "twins". Therefore, the generic functions `pltree` and `as.hclust` are available for agnes objects. After applying `as.hclust()`, all *its* methods are available, of course.

See Also

`agnes`, `diana`, `as.hclust`, `hclust`, `plot.agnes`, `twins.object`, `cutree`.

Examples

```
data(agriculture)
ag.ag <- agnes(agriculture)
class(ag.ag)
pltree(ag.ag) # the dendrogram

## cut the dendrogram -> get cluster assignments:
(ck3 <- cutree(ag.ag, k = 3))
(ch6 <- cutree(as.hclust(ag.ag), h = 6))
stopifnot(identical(unname(ch6), ck3))
```

---

|             |   |
|-------------|---|
| agriculture | <i>European Union Agricultural Workforces</i> |
|-------------|---|

---

Description

Gross National Product (GNP) per capita and percentage of the population working in agriculture for each country belonging to the European Union in 1993.

Usage

```
data(agriculture)
```

Format

A data frame with 12 observations on 2 variables:

|        |   |         |                           |
|--------|---|---------|---------------------------|
| [ , 1] | x | numeric | per capita GNP            |
| [ , 2] | y | numeric | percentage in agriculture |

The row names of the data frame indicate the countries.

### Details

The data seem to show two clusters, the “more agricultural” one consisting of Greece, Portugal, Spain, and Ireland.

### Source

Eurostat (European Statistical Agency, 1994): *Cijfers en feiten: Een statistisch portret van de Europese Unie*.

### References

see those in [agnes](#).

### Examples

```
data(agriculture)

## Compute the dissimilarities using Euclidean metric and without
## standardization
daisy(agriculture, metric = "euclidean", stand = FALSE)

## 2nd plot is similar to Figure 3 in Struyf et al (1996)
plot(pam(agriculture, 2))

## Plot similar to Figure 7 in Struyf et al (1996)
## Not run: plot(agnes(agriculture), ask = TRUE)

## Plot similar to Figure 8 in Struyf et al (1996)
## Not run: plot(diana(agriculture), ask = TRUE)
```

---

animals

*Attributes of Animals*

---

### Description

This data set considers 6 binary attributes for 20 animals.

### Usage

```
data(animals)
```

### Format

A data frame with 20 observations on 6 variables:

|        |     |                |
|--------|-----|----------------|
| [ , 1] | war | warm-blooded   |
| [ , 2] | fly | can fly        |
| [ , 3] | ver | vertebrate     |
| [ , 4] | end | endangered     |
| [ , 5] | gro | live in groups |
| [ , 6] | hai | have hair      |

All variables are encoded as 1 = 'no', 2 = 'yes'.

### Details

This dataset is useful for illustrating monothetic (only a single variable is used for each split) hierarchical clustering.

Leonard Kaufman and Peter J. Rousseeuw (1990): *Finding Groups in Data* (pp 297ff). New York: Wiley.

### References

see Struyf, Hubert & Rousseeuw (1996), in [agnes](#).

### Examples

```
data(animals)
apply(animals, 2, table) # simple overview

ma <- mona(animals)
ma
## Plot similar to Figure 10 in Struyf et al (1996)
plot(ma)
```

---

bannerplot

*Plot Banner (of Hierarchical Clustering)*

---

### Description

Draws a “banner”, i.e. basically a horizontal [barplot](#) visualizing the (agglomerative or divisive) hierarchical clustering or an other binary dendrogram structure.

### Usage

```
bannerplot(x, w = rev(x$height), fromLeft = TRUE,
           main=NULL, sub=NULL, xlab = "Height", adj = 0,
           col = c(2, 0), border = 0, axes = TRUE, frame.plot = axes,
           rev.xax = !fromLeft, xax.pretty = TRUE,
           labels = NULL, nmax.lab = 35, max.strlen = 5,
           yax.do = axes && length(x$order) <= nmax.lab,
           yaxRight = fromLeft, y.mar = 2.4 + max.strlen/2.5, ...)
```

**Arguments**

|                         |   |
|-------------------------|---|
| <code>x</code>          | a list with components <code>order</code> , <code>order.lab</code> and <code>height</code> when <code>w</code> , the next argument is not specified.                              |
| <code>w</code>          | non-negative numeric vector of bar widths.  |
| <code>fromLeft</code>   | logical, indicating if the banner is from the left or not.  |
| <code>main, sub</code>  | main and sub titles, see <a href="#">title</a> .  |
| <code>xlab</code>       | x axis label (with ‘correct’ default e.g. for <code>plot.agnes</code> ).  |
| <code>adj</code>        | passed to <a href="#">title</a> ( <code>main, sub</code> ) for string adjustment.   |
| <code>col</code>        | vector of length 2, for two horizontal segments.  |
| <code>border</code>     | color for bar border; now defaults to background (no border).   |
| <code>axes</code>       | logical indicating if axes (and labels) should be drawn at all.   |
| <code>frame.plot</code> | logical indicating the banner should be framed; mainly used when <code>border = 0</code> (as per default).  |
| <code>rev.xax</code>    | logical indicating if the x axis should be reversed (as in <code>plot.diana</code> ).   |
| <code>xax.pretty</code> | logical or integer indicating if <a href="#">pretty()</a> should be used for the x axis. <code>xax.pretty = FALSE</code> is mainly for back compatibility.                        |
| <code>labels</code>     | labels to use on y-axis; the default is constructed from <code>x</code> .   |
| <code>nmax.lab</code>   | integer indicating the number of labels which is considered too large for single-name labelling the banner plot.  |
| <code>max.strlen</code> | positive integer giving the length to which strings are truncated in banner plot labeling.  |
| <code>yax.do</code>     | logical indicating if a y axis and banner labels should be drawn.   |
| <code>yaxRight</code>   | logical indicating if the y axis is on the right or left.   |
| <code>y.mar</code>      | positive number specifying the margin width to use when banners are labeled (along a y-axis). The default adapts to the string width and optimally would also depend on the font. |
| <code>...</code>        | graphical parameters (see <a href="#">par</a> ) may also be supplied as arguments to this function.   |

**Note**

This is mainly a utility called from [plot.agnes](#), [plot.diana](#) and [plot.mona](#).

**Author(s)**

Martin Maechler (from original code of Kaufman and Rousseeuw).

**Examples**

```
data(agriculture)
bannerplot(agnes(agriculture), main = "Bannerplot")
```

---

chorSub*Subset of C-horizon of Kola Data*

---

## Description

This is a small rounded subset of the C-horizon data [chorizon](#) from package **mvoutlier**.

## Usage

```
data(chorSub)
```

## Format

A data frame with 61 observations on 10 variables. The variables contain scaled concentrations of chemical elements.

## Details

This data set was produced from `chorizon` via these statements:

```
data(chorizon, package = "mvoutlier")
chorSub <- round(100*scale(chorizon[,101:110]))[190:250,]
storage.mode(chorSub) <- "integer"
colnames(chorSub) <- gsub("_.*", "", colnames(chorSub))
```

## Source

Kola Project (1993-1998)

## See Also

[chorizon](#) in package **mvoutlier** and other Kola data in the same package.

## Examples

```
data(chorSub)
summary(chorSub)
pairs(chorSub, gap= .1)# some outliers
```

## Description

Computes a "clara" object, a [list](#) representing a clustering of the data into  $k$  clusters.

## Usage

```
clara(x, k, metric = c("euclidean", "manhattan", "jaccard"),
      stand = FALSE, cluster.only = FALSE, samples = 5,
      sampsize = min(n, 40 + 2 * k), trace = 0, medoids.x = TRUE,
      keep.data = medoids.x, rngR = FALSE, pamLike = FALSE, correct.d = TRUE)
```

## Arguments

- |                           |  |
|---------------------------|--|
| <code>x</code>            | data matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric (or logical). Missing values (NAs) are allowed.  |
| <code>k</code>            | integer, the number of clusters. It is required that $0 < k < n$ where $n$ is the number of observations (i.e., $n = \text{nrow}(x)$ ).  |
| <code>metric</code>       | character string specifying the metric to be used for calculating dissimilarities between observations. The currently available options are "euclidean", "manhattan", "jaccard".<br>Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences.   |
| <code>stand</code>        | logical, indicating if the measurements in <code>x</code> are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation.  |
| <code>cluster.only</code> | logical; if true, only the clustering will be computed and returned, see details.  |
| <code>samples</code>      | integer, say $N$ , the number of samples to be drawn from the dataset. The default, $N = 5$ , is rather small for historical (and now back compatibility) reasons and we <i>recommend to set samples an order of magnitude larger</i> .  |
| <code>sampsize</code>     | integer, say $j$ , the number of observations in each sample. <code>sampsize</code> should be higher than the number of clusters ( $k$ ) and at most the number of observations ( $n = \text{nrow}(x)$ ). While computational effort is proportional to $j^2$ , see note below, it may still be advisable to set $j = \text{sampsize}$ to a <i>larger</i> value than the (historical) default. |
| <code>trace</code>        | integer indicating a <i>trace level</i> for diagnostic output during the algorithm.  |
| <code>medoids.x</code>    | logical indicating if the medoids should be returned, identically to some rows of the input data <code>x</code> . If FALSE, <code>keep.data</code> must be false as well, and the medoid indices, i.e., row numbers of the medoids will still be returned ( <code>i.med</code> component), and the algorithm saves space by needing one copy less of <code>x</code> .                          |
| <code>keep.data</code>    | logical indicating if the ( <i>scaled</i> if <code>stand</code> is true) data should be kept in the result. Setting this to FALSE saves memory (and hence time), but disables <a href="#">clusplot()</a> ing of the result. Use <code>medoids.x = FALSE</code> to save even more memory.   |

|                        |   |
|------------------------|---|
| <code>rngR</code>      | logical indicating if R's random number generator should be used instead of the primitive <code>clara()</code> -builtin one. If true, this also means that each call to <code>clara()</code> returns a different result – though only slightly different in good situations.  |
| <code>pamLike</code>   | logical indicating if the “swap” phase (see <a href="#">pam</a> , in C code) should use the same algorithm as <code>pam()</code> . Note that from Kaufman and Rousseeuw's description this <i>should</i> have been true always, but as the original Fortran code and the subsequent port to C has always contained a small one-letter change (a typo according to Martin Maechler) with respect to PAM, the default, <code>pamLike = FALSE</code> has been chosen to remain back compatible rather than “PAM compatible”. |
| <code>correct.d</code> | logical or integer indicating that—only in the case of NAs present in <code>x</code> —the correct distance computation should be used instead of the wrong formula which has been present in the original Fortran code and been in use up to early 2016.<br>Because the new correct formula is not back compatible, for the time being, a warning is signalled in this case, unless the user explicitly specifies <code>correct.d</code> .  |

### Details

`clara` (for “euclidean” and “manhattan”) is fully described in chapter 3 of Kaufman and Rousseeuw (1990). Compared to other partitioning methods such as `pam`, it can deal with much larger datasets. Internally, this is achieved by considering sub-datasets of fixed size (`sampsize`) such that the time and storage requirements become linear in  $n$  rather than quadratic.

Each sub-dataset is partitioned into  $k$  clusters using the same algorithm as in `pam`.

Once  $k$  representative objects have been selected from the sub-dataset, each observation of the entire dataset is assigned to the nearest medoid.

The mean (equivalent to the sum) of the dissimilarities of the observations to their closest medoid is used as a measure of the quality of the clustering. The sub-dataset for which the mean (or sum) is minimal, is retained. A further analysis is carried out on the final partition.

Each sub-dataset is forced to contain the medoids obtained from the best sub-dataset until then. Randomly drawn observations are added to this set until `sampsize` has been reached.

When `cluster.only` is true, the result is simply a (possibly named) integer vector specifying the clustering, i.e.,

`clara(x, k, cluster.only=TRUE)` is the same as  
`clara(x, k)$clustering` but computed more efficiently.

### Value

If `cluster.only` is false (as by default), an object of class “`clara`” representing the clustering. See [clara.object](#) for details.

If `cluster.only` is true, the result is the “clustering”, an integer vector of length  $n$  with entries from  $1:k$ .

### Note

By default, the random sampling is implemented with a *very* simple scheme (with period  $2^{16} = 65536$ ) inside the Fortran code, independently of R's random number generation, and as a matter of fact, deterministically. Alternatively, we recommend setting `rngR = TRUE` which uses R's random number generators. Then, `clara()` results are made reproducible typically by using `set.seed()` before calling `clara`.

The storage requirement of clara computation (for small  $k$ ) is about  $O(n \times p) + O(j^2)$  where  $j = \text{sampsiz}$ e, and  $(n, p) = \text{dim}(x)$ . The CPU computing time (again assuming small  $k$ ) is about  $O(n \times p \times j^2 \times N)$ , where  $N = \text{samples}$ .

For “small” datasets, the function `pam` can be used directly. What can be considered *small*, is really a function of available computing power, both memory (RAM) and speed. Originally (1990), “small” meant less than 100 observations; in 1997, the authors said “*small (say with fewer than 200 observations)*”; as of 2006, you can use `pam` with several thousand observations.

### Author(s)

Kaufman and Rousseeuw (see `agnes`), originally. Metric “jaccard”: Kamil Kozłowski (@ownedoutcomes.com) and Kamil Jadeszko. All arguments from `trace` on, and most R documentation and all tests by Martin Maechler.

### See Also

`agnes` for background and references; `clara.object`, `pam`, `partition.object`, `plot.partition`.

### Examples

```
## generate 500 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(200,0,8), rnorm(200,0,8)),
           cbind(rnorm(300,50,8), rnorm(300,50,8)))
clarax <- clara(x, 2, samples=50)
clarax
clarax$clusinfo
## using pamLike=TRUE gives the same (apart from the 'call'):
all.equal(clarax[-8],
          clara(x, 2, samples=50, pamLike = TRUE)[-8])
plot(clarax)

## cluster.only = TRUE -- save some memory/time :
clclus <- clara(x, 2, samples=50, cluster.only = TRUE)
stopifnot(identical(clclus, clarax$clustering))

## 'xclara' is an artificial data set with 3 clusters of 1000 bivariate
## objects each.
data(xclara)
(clx3 <- clara(xclara, 3))
## "better" number of samples
cl.3 <- clara(xclara, 3, samples=100)
## but that did not change the result here:
stopifnot(cl.3$clustering == clx3$clustering)
## Plot similar to Figure 5 in Struyf et al (1996)
## Not run: plot(clx3, ask = TRUE)

## Try 100 times *different* random samples -- for reliability:
nSim <- 100
nCl <- 3 # = no.classes
set.seed(421) # (reproducibility)
cl <- matrix(NA, nrow(xclara), nSim)
for(i in 1:nSim)
  cl[,i] <- clara(xclara, nCl, medoids.x = FALSE, rngR = TRUE)$cluster
```

```

tcl <- apply(cl,1, tabulate, nbins = nCl)
## those that are not always in same cluster (5 out of 3000 for this seed):
(iDoubt <- which(apply(tcl,2, function(n) all(n < nSim))))
if(length(iDoubt)) { # (not for all seeds)
  tabD <- tcl[,iDoubt, drop=FALSE]
  dimnames(tabD) <- list(cluster = paste(1:nCl), obs = format(iDoubt))
  t(tabD) # how many times in which clusters
}

```

---

clara.object

---

*Clustering Large Applications (CLARA) Object*

---

## Description

The objects of class "clara" represent a partitioning of a large dataset into clusters and are typically returned from [clara](#).

## Value

A legitimate clara object is a list with the following components:

|            |   |
|------------|---|
| sample     | labels or case numbers of the observations in the best sample, that is, the sample used by the clara algorithm for the final partition.   |
| medoids    | the medoids or representative objects of the clusters. It is a matrix with in each row the coordinates of one medoid. Possibly NULL, namely when the object resulted from clara(*, medoids.x=FALSE). Use the following i.med in that case.  |
| i.med      | the <i>indices</i> of the medoids above: medoids <- x[i.med, ] where x is the original data matrix in clara(x, *).  |
| clustering | the clustering vector, see <a href="#">partition.object</a> .   |
| objective  | the objective function for the final clustering of the entire dataset.  |
| clusinfo   | matrix, each row gives numerical information for one cluster. These are the cardinality of the cluster (number of observations), the maximal and average dissimilarity between the observations in the cluster and the cluster's medoid. The last column is the maximal dissimilarity between the observations in the cluster and the cluster's medoid, divided by the minimal dissimilarity between the cluster's medoid and the medoid of any other cluster. If this ratio is small, the cluster is well-separated from the other clusters. |
| diss       | dissimilarity (maybe NULL), see <a href="#">partition.object</a> .  |
| silinfo    | list with silhouette width information for the best sample, see <a href="#">partition.object</a> .  |
| call       | generating call, see <a href="#">partition.object</a> .   |
| data       | matrix, possibly standardized, or NULL, see <a href="#">partition.object</a> .  |

## Methods, Inheritance

The "clara" class has methods for the following generic functions: print, summary.

The class "clara" inherits from "partition". Therefore, the generic functions plot and clusplot can be used on a clara object.

**See Also**

[clara](#), [dissimilarity.object](#), [partition.object](#), [plot.partition](#).

clusGap

*Gap Statistic for Estimating the Number of Clusters***Description**

`clusGap()` calculates a goodness of clustering measure, the “gap” statistic. For each number of clusters  $k$ , it compares  $\log(W(k))$  with  $E^*[\log(W(k))]$  where the latter is defined via bootstrapping, i.e., simulating from a reference ( $H_0$ ) distribution, a uniform distribution on the hypercube determined by the ranges of  $x$ , after first centering, and then [svd](#) (aka ‘PCA’)-rotating them when (as by default) `spaceH0 = "scaledPCA"`.

`maxSE(f, SE.f)` determines the location of the **maximum** of  $f$ , taking a “1-SE rule” into account for the `*SE*` methods. The default method `"firstSEmax"` looks for the smallest  $k$  such that its value  $f(k)$  is not more than 1 standard error away from the first local maximum. This is similar but not the same as `"Tibs2001SEmax"`, Tibshirani et al’s recommendation of determining the number of clusters from the gap statistics and their standard deviations.

**Usage**

```
clusGap(x, FUNcluster, K.max, B = 100, d.power = 1,
        spaceH0 = c("scaledPCA", "original"),
        verbose = interactive(), ...)

maxSE(f, SE.f,
      method = c("firstSEmax", "Tibs2001SEmax", "globalSEmax",
                  "firstmax", "globalmax"),
      SE.factor = 1)

## S3 method for class 'clusGap'
print(x, method = "firstSEmax", SE.factor = 1, ...)

## S3 method for class 'clusGap'
plot(x, type = "b", xlab = "k", ylab = expression(Gap[k]),
      main = NULL, do.arrows = TRUE,
      arrowArgs = list(col="red3", length=1/16, angle=90, code=3), ...)
```

**Arguments**

|                         |   |
|-------------------------|---|
| <code>x</code>          | numeric matrix or <a href="#">data.frame</a> .  |
| <code>FUNcluster</code> | a <a href="#">function</a> which accepts as first argument a (data) matrix like <code>x</code> , second argument, say $k$ , $k \geq 2$ , the number of clusters desired, and returns a <a href="#">list</a> with a component named (or shortened to) <code>cluster</code> which is a vector of length $n = \text{nrow}(x)$ of integers in $1:k$ determining the clustering or grouping of the $n$ observations. |
| <code>K.max</code>      | the maximum number of clusters to consider, must be at least two.   |
| <code>B</code>          | integer, number of Monte Carlo (“bootstrap”) samples.   |

|                        |  |
|------------------------|--|
| d.power                | a positive integer specifying the power $p$ which is applied to the euclidean distances ( <code>dist</code> ) before they are summed up to give $W(k)$ . The default, <code>d.power = 1</code> , corresponds to the “historical” R implementation, whereas <code>d.power = 2</code> corresponds to what Tibshirani et al had proposed. This was found by Juan Gonzalez, in 2016-02.  |
| spaceH0                | a <code>character</code> string specifying the space of the $H_0$ distribution (of <i>no</i> cluster). Both <code>"scaledPCA"</code> and <code>"original"</code> use a uniform distribution in a hyper cube and had been mentioned in the reference; <code>"original"</code> been added after a proposal (including code) by Juan Gonzalez.  |
| verbose                | integer or logical, determining if “progress” output should be printed. The default prints one bit per bootstrap sample.   |
| ...                    | (for <code>clusGap()</code> ) optionally further arguments for <code>FUNcluster()</code> , see <code>kmeans</code> example below.  |
| f                      | numeric vector of ‘function values’, of length $K$ , whose (“1 SE respected”) maximum we want.   |
| SE.f                   | numeric vector of length $K$ of standard errors of <code>f</code> .  |
| method                 | <p>character string indicating how the “optimal” number of clusters, <math>\hat{k}</math>, is computed from the gap statistics (and their standard deviations), or more generally how the location <math>\hat{k}</math> of the maximum of <math>f_k</math> should be determined.</p> <p><code>"globalmax"</code>: simply corresponds to the global maximum, i.e., is <code>which.max(f)</code></p> <p><code>"firstmax"</code>: gives the location of the first <i>local</i> maximum.</p> <p><code>"Tibs2001SEmax"</code>: uses the criterion, Tibshirani et al (2001) proposed: “the smallest <math>k</math> such that <math>f(k) \geq f(k+1) - s_{k+1}</math>”. Note that this chooses <math>k = 1</math> when all standard deviations are larger than the differences <math>f(k+1) - f(k)</math>.</p> <p><code>"firstSEmax"</code>: location of the first <math>f()</math> value which is not smaller than the first <i>local</i> maximum minus <code>SE.factor * SE.f[]</code>, i.e, within an “f S.E.” range of that maximum (see also <code>SE.factor</code>).</p> <p>This, the default, has been proposed by Martin Maechler in 2012, when adding <code>clusGap()</code> to the <b>cluster</b> package, after having seen the <code>"globalSEmax"</code> proposal (in code) and read the <code>"Tibs2001SEmax"</code> proposal.</p> <p><code>"globalSEmax"</code>: (used in Dudoit and Fridlyand (2002), supposedly following Tibshirani’s proposition): location of the first <math>f()</math> value which is not smaller than the <i>global</i> maximum minus <code>SE.factor * SE.f[]</code>, i.e, within an “f S.E.” range of that maximum (see also <code>SE.factor</code>).</p> <p>See the examples for a comparison in a simple case.</p> |
| SE.factor              | [When <code>method</code> contains <code>"SE"</code> ] Determining the optimal number of clusters, Tibshirani et al. proposed the “1 S.E.”-rule. Using an <code>SE.factor f</code> , the “f S.E.”-rule is used, more generally.  |
| type, xlab, ylab, main | arguments with the same meaning as in <code>plot.default()</code> , with different default.  |
| do.arrows              | logical indicating if (1 SE -)“error bars” should be drawn, via <code>arrows()</code> .  |
| arrowArgs              | a list of arguments passed to <code>arrows()</code> ; the default, notably <code>angle</code> and <code>code</code> , provide a style matching usual error bars.   |

## Details

The main result `<res>$Tab[, "gap"]` of course is from bootstrapping aka Monte Carlo simulation and hence random, or equivalently, depending on the initial random seed (see `set.seed()`). On the other hand, in our experience, using `B = 500` gives quite precise results such that the gap plot is basically unchanged after an another run.

## Value

`clusGap(.)` returns an object of S3 class `"clusGap"`, basically a list with components

|                         |   |
|-------------------------|---|
| <code>Tab</code>        | a matrix with <code>K.max</code> rows and 4 columns, named <code>"logW"</code> , <code>"E.logW"</code> , <code>"gap"</code> , and <code>"SE.sim"</code> , where <code>gap = E.logW - logW</code> , and <code>SE.sim</code> corresponds to the standard error of <code>gap</code> , <code>SE.sim[k] = s<sub>k</sub></code> , where $s_k := \sqrt{1 + 1/B} sd^*(gap_j)$ , and <code>sd^*</code> is the standard deviation of the simulated (“bootstrapped”) gap values. |
| <code>call</code>       | the <code>clusGap(.)</code> call.   |
| <code>spaceH0</code>    | the <code>spaceH0</code> argument ( <code>match.arg()</code> ed).   |
| <code>n</code>          | number of observations, i.e., <code>nrow(x)</code> .  |
| <code>B</code>          | input <code>B</code>  |
| <code>FUNcluster</code> | input function <code>FUNcluster</code>  |

## Author(s)

This function is originally based on the functions `gap` of former (Bioconductor) package **SAGx** by Per Broberg, `gapStat()` from former package **SLmisc** by Matthias Kohl and ideas from `gap()` and its methods of package **lga** by Justin Harrington.

The current implementation is by Martin Maechler.

The implementation of `spaceH0 = "original"` is based on code proposed by Juan Gonzalez.

gsP.Z

```

clusplot

*Bivariate Cluster Plot (of a Partitioning Object)*

## Description

Draws a 2-dimensional “clusplot” (clustering plot) on the current graphics device. The generic function has a default and a partition method.

## Usage

```

clusplot(x, ...)

## S3 method for class 'partition'
clusplot(x, main = NULL, dist = NULL, ...)

```

## Arguments

|                   |  |
|-------------------|--|
| <code>x</code>    | an R object, here, specifically an object of class "partition", e.g. created by one of the functions <a href="#">pam</a> , <a href="#">clara</a> , or <a href="#">fanny</a> .  |
| <code>main</code> | title for the plot; when NULL (by default), a title is constructed, using <code>x\$call</code> .   |
| <code>dist</code> | when <code>x</code> does not have a <code>diss</code> nor a <code>data</code> component, e.g., for <a href="#">pam</a> ( <code>dist(*)</code> , <code>keep.diss=FALSE</code> ), <code>dist</code> must specify the dissimilarity for the <code>clusplot</code> .     |
| <code>...</code>  | optional arguments passed to methods, notably the <a href="#">clusplot.default</a> method (except for the <code>diss</code> one) may also be supplied to this function. Many graphical parameters (see <a href="#">par</a> ) may also be supplied as arguments here. |

## Details

The `clusplot.partition()` method relies on [clusplot.default](#).

If the clustering algorithms [pam](#), [fanny](#) and [clara](#) are applied to a data matrix of observations-by-variables then a `clusplot` of the resulting clustering can always be drawn. When the data matrix contains missing values and the clustering is performed with [pam](#) or [fanny](#), the dissimilarity matrix will be given as input to `clusplot`. When the clustering algorithm [clara](#) was applied to a data matrix with `NA`s then `clusplot()` will replace the missing values as described in [clusplot.default](#), because a dissimilarity matrix is not available.

**Value**

For the partition (and default) method: An invisible list with components `Distances` and `Shading`, as for `clusplot.default`, see there.

**Side Effects**

a 2-dimensional clusplot is created on the current graphics device.

**See Also**

`clusplot.default` for references; `partition.object`, `pam`, `pam.object`, `clara`, `clara.object`, `fanny`, `fanny.object`, `par`.

**Examples**

```
## For more, see ?clusplot.default

## generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),
           cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
clusplot(pam(x, 2))
## add noise, and try again :
x4 <- cbind(x, rnorm(25), rnorm(25))
clusplot(pam(x4, 2))
```

---

|                               |   |
|-------------------------------|---|
| <code>clusplot.default</code> | <i>Bivariate Cluster Plot (clusplot) Default Method</i> |
|-------------------------------|---|

---

**Description**

Creates a bivariate plot visualizing a partition (clustering) of the data. All observation are represented by points in the plot, using principal components or multidimensional scaling. Around each cluster an ellipse is drawn.

**Usage**

```
## Default S3 method:
clusplot(x, clus, diss = FALSE,
         s.x.2d = mkCheckX(x, diss), stand = FALSE,
         lines = 2, shade = FALSE, color = FALSE,
         labels = 0, plotchar = TRUE,
         col.p = "dark green", col.txt = col.p,
         col.clus = if(color) c(2, 4, 6, 3) else 5, cex = 1, cex.txt = cex,
         span = TRUE,
         add = FALSE,
         xlim = NULL, ylim = NULL,
         main = paste("CLUSPLOT(", deparse1(substitute(x)), ")"),
         sub = paste("These two components explain",
                     round(100 * var.dec, digits = 2), "% of the point variability."),
         xlab = "Component 1", ylab = "Component 2",
         verbose = getOption("verbose"),
         ...)
```

## Arguments

|                     |   |
|---------------------|---|
| <code>x</code>      | <p>matrix or data frame, or dissimilarity matrix, depending on the value of the <code>diss</code> argument.</p> <p>In case of a matrix (alike), each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed. They are replaced by the median of the corresponding variable. When some variables or some observations contain only missing values, the function stops with a warning message.</p> <p>In case of a dissimilarity matrix, <code>x</code> is the output of <code>daisy</code> or <code>dist</code> or a symmetric matrix. Also, a vector of length <math>n * (n - 1) / 2</math> is allowed (where <math>n</math> is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.</p>   |
| <code>clus</code>   | <p>a vector of length <math>n</math> representing a clustering of <code>x</code>. For each observation the vector lists the number or name of the cluster to which it has been assigned. <code>clus</code> is often the clustering component of the output of <code>pam</code>, <code>fanny</code> or <code>clara</code>.</p>   |
| <code>diss</code>   | <p>logical indicating if <code>x</code> will be considered as a dissimilarity matrix or a matrix of observations by variables (see <code>x</code> argument above).</p>  |
| <code>s.x.2d</code> | <p>a <code>list</code> with components named <code>x</code> (a <math>n \times 2</math> matrix; typically something like principal components of original data), <code>labs</code> and <code>var.dec</code>.</p>   |
| <code>stand</code>  | <p>logical flag: if true, then the representations of the <math>n</math> observations in the 2-dimensional plot are standardized.</p>   |
| <code>lines</code>  | <p>integer out of 0, 1, 2, used to obtain an idea of the distances between ellipses. The distance between two ellipses E1 and E2 is measured along the line connecting the centers <math>m1</math> and <math>m2</math> of the two ellipses.</p> <p>In case E1 and E2 overlap on the line through <math>m1</math> and <math>m2</math>, no line is drawn. Otherwise, the result depends on the value of <code>lines</code>: If</p> <p><b>lines = 0</b>, no distance lines will appear on the plot;</p> <p><b>lines = 1</b>, the line segment between <math>m1</math> and <math>m2</math> is drawn;</p> <p><b>lines = 2</b>, a line segment between the boundaries of E1 and E2 is drawn (along the line connecting <math>m1</math> and <math>m2</math>).</p>  |
| <code>shade</code>  | <p>logical flag: if TRUE, then the ellipses are shaded in relation to their density. The density is the number of points in the cluster divided by the area of the ellipse.</p>   |
| <code>color</code>  | <p>logical flag: if TRUE, then the ellipses are colored with respect to their density. With increasing density, the colors are light blue, light green, red and purple. To see these colors on the graphics device, an appropriate color scheme should be selected (we recommend a white background).</p>   |
| <code>labels</code> | <p>integer code, currently one of 0,1,2,3,4 and 5. If</p> <p><b>labels= 0</b>, no labels are placed in the plot;</p> <p><b>labels= 1</b>, points and ellipses can be identified in the plot (see <code>identify</code>);</p> <p><b>labels= 2</b>, all points and ellipses are labelled in the plot;</p> <p><b>labels= 3</b>, only the points are labelled in the plot;</p> <p><b>labels= 4</b>, only the ellipses are labelled in the plot.</p> <p><b>labels= 5</b>, the ellipses are labelled in the plot, and points can be identified.</p> <p>The levels of the vector <code>clus</code> are taken as labels for the clusters. The labels of the points are the rownames of <code>x</code> if <code>x</code> is matrix like. Otherwise (<code>diss = TRUE</code>), <code>x</code> is a vector, point labels can be attached to <code>x</code> as a "Labels" attribute (<code>attr(x, "Labels")</code>), as is done for the output of <code>daisy</code>.</p> <p>A possible <code>names</code> attribute of <code>clus</code> will not be taken into account.</p> |

|              |   |
|--------------|---|
| plotchar     | logical flag: if TRUE, then the plotting symbols differ for points belonging to different clusters.   |
| span         | logical flag: if TRUE, then each cluster is represented by the ellipse with smallest area containing all its points. (This is a special case of the minimum volume ellipsoid.)<br>If FALSE, the ellipse is based on the mean and covariance matrix of the same points. While this is faster to compute, it often yields a much larger ellipse.<br>There are also some special cases: When a cluster consists of only one point, a tiny circle is drawn around it. When the points of a cluster fall on a straight line, <code>span=FALSE</code> draws a narrow ellipse around it and <code>span=TRUE</code> gives the exact line segment. |
| add          | logical indicating if ellipses (and labels if <code>labels</code> is true) should be <i>added</i> to an already existing plot. If false, neither a <code>title</code> or sub title, see <code>sub</code> , is written.  |
| col.p        | color code(s) used for the observation points.  |
| col.txt      | color code(s) used for the labels (if <code>labels &gt;= 2</code> ).  |
| col.clus     | color code for the ellipses (and their labels); only one if <code>color</code> is false (as per default).   |
| cex, cex.txt | character <b>expansion</b> (size), for the point symbols and point labels, respectively.  |
| xlim, ylim   | numeric vectors of length 2, giving the x- and y- ranges as in <code>plot.default</code> .  |
| main         | main title for the plot; by default, one is constructed.  |
| sub          | sub title for the plot; by default, one is constructed.   |
| xlab, ylab   | x- and y- axis labels for the plot, with defaults.  |
| verbose      | a logical indicating, if there should be extra diagnostic output; mainly for ‘debugging’.   |
| ...          | Further graphical parameters may also be supplied, see <code>par</code> .   |

### Details

clusplot uses function calls `princomp(*, cor = (ncol(x) > 2))` or `cmdscale(*, add=TRUE)`, respectively, depending on `diss` being false or true. These functions are data reduction techniques to represent the data in a bivariate plot.

Ellipses are then drawn to indicate the clusters. The further layout of the plot is determined by the optional arguments.

### Value

An invisible list with components:

|           |  |
|-----------|--|
| Distances | When <code>lines</code> is 1 or 2 we obtain a $k$ by $k$ matrix ( $k$ is the number of clusters). The element in $[i, j]$ is the distance between ellipse $i$ and ellipse $j$ .<br>If <code>lines = 0</code> , then the value of this component is NA.   |
| Shading   | A vector of length $k$ (where $k$ is the number of clusters), containing the amount of shading per cluster. Let $y$ be a vector where element $i$ is the ratio between the number of points in cluster $i$ and the area of ellipse $i$ . When the cluster $i$ is a line segment, $y[i]$ and the density of the cluster are set to NA. Let $z$ be the sum of all the elements of $y$ without the NAs. Then we put <code>shading = y/z * 37 + 3</code> . |

### Side Effects

a visual display of the clustering is plotted on the current graphics device.

## Note

When we have 4 or fewer clusters, then the `color=TRUE` gives every cluster a different color. When there are more than 4 clusters, `clusplot` uses the function `pam` to cluster the densities into 4 groups such that ellipses with nearly the same density get the same color. `col.clus` specifies the colors used.

The `col.p` and `col.txt` arguments, added for R, are recycled to have length the number of observations. If `col.p` has more than one value, using `color = TRUE` can be confusing because of a mix of point and ellipse colors.

# reset graphics
par(op)
```

coef.hclust

*Agglomerative / Divisive Coefficient for 'hclust' Objects*

## Description

Computes the “agglomerative coefficient” (aka “divisive coefficient” for [diana](#)), measuring the clustering structure of the dataset.

For each observation  $i$ , denote by  $m(i)$  its dissimilarity to the first cluster it is merged with, divided by the dissimilarity of the merger in the final step of the algorithm. The agglomerative coefficient is the average of all  $1 - m(i)$ . It can also be seen as the average width (or the percentage filled) of the banner plot.

`coefHier()` directly interfaces to the underlying C code, and “proves” that *only* `object$heights` is needed to compute the coefficient.

Because it grows with the number of observations, this measure should not be used to compare datasets of very different sizes.

## Usage

```
coefHier(object)
coef.hclust(object, ...)
## S3 method for class 'hclust'
coef(object, ...)
## S3 method for class 'twins'
coef(object, ...)
```

## Arguments

`object` an object of class "hclust" or "twins", i.e., typically the result of `hclust(.)`, `agnes(.)`, or `diana(.)`.

Since `coef.hclust` only uses `object$heights`, and `object$merge`, `object` can be any list-like object with appropriate merge and heights components.

For `coefHier`, even only `object$heights` is needed.

... currently unused potential further arguments

### Value

a number specifying the *agglomerative* (or *divisive* for `diana` objects) coefficient as defined by Kaufman and Rousseeuw, see `agnes.object` \$ `ac` or `diana.object` \$ `dc`.

### Examples

```
data(agriculture)
aa <- agnes(agriculture)
coef(aa) # really just extracts aa$ac
coef(as.hclust(aa)) # recomputes
coefHier(aa) # ditto
```

---

daisy

Dissimilarity Matrix Calculation

---

### Description

Compute all the pairwise dissimilarities (distances) between observations in the data set. The original variables may be of mixed types. In that case, or whenever `metric = "gower"` is set, a generalization of Gower's formula is used, see 'Details' below.

### Usage

```
daisy(x, metric = c("euclidean", "manhattan", "gower"),
      stand = FALSE, type = list(), weights = rep.int(1, p),
      warnBin = warnType, warnAsym = warnType, warnConst = warnType,
      warnType = TRUE)
```

### Arguments

|                     |   |
|---------------------|---|
| <code>x</code>      | numeric matrix or data frame, of dimension $n \times p$ , say. Dissimilarities will be computed between the rows of <code>x</code> . Columns of mode <code>numeric</code> (i.e. all columns when <code>x</code> is a matrix) will be recognized as interval scaled variables, columns of class <code>factor</code> will be recognized as nominal variables, and columns of class <code>ordered</code> will be recognized as ordinal variables. Other variable types should be specified with the <code>type</code> argument. Missing values (NAs) are allowed.  |
| <code>metric</code> | character string specifying the metric to be used. The currently available options are "euclidean" (the default), "manhattan" and "gower". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences.<br><br>"Gower's distance" is chosen by metric "gower" or automatically if some columns of <code>x</code> are not numeric. Also known as Gower's coefficient (1971), expressed as a dissimilarity, this implies that a particular standardisation will be applied to each variable, and the "distance" between two units is the sum of all the variable-specific distances, see the details section. |

|                              |  |
|------------------------------|--|
| stand                        | <p>logical flag: if TRUE, then the measurements in <code>x</code> are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation.</p> <p>If not all columns of <code>x</code> are numeric, <code>stand</code> will be ignored and Gower's standardization (based on the <a href="#">range</a>) will be applied in any case, see argument <code>metric</code>, above, and the details section.</p>  |
| type                         | <p>list for specifying some (or all) of the types of the variables (columns) in <code>x</code>. The list may contain the following components:</p> <p>"asymm" Asymmetric binary variable, aka "A" in result Types, see <a href="#">dissimilarity.object</a>.</p> <p>"symm" Symmetric binary variable, aka "S".</p> <p>"factor" Nominal – the default for <a href="#">factor</a> variables, aka "N". When the factor has 2 levels, this is equivalent to <code>type = "S"</code> for a (symmetric) binary variable.</p> <p>"ordered" Ordinal – the default for <a href="#">ordered</a> (factor) variables, aka "O", see <a href="#">dissimilarity.object</a>.</p> <p>"logratio" ratio scaled numeric variables that are to be logarithmically transformed (<a href="#">log10</a>) and then treated as numeric ("I"): must be <i>positive</i> numeric variable.</p> <p>"ordratio" "raTio"-like variable to be treated as <a href="#">ordered</a> (using the factor codes <code>unclass(as.ordered(x[,j]))</code>), aka "T".</p> <p>"numeric"/"integer" Interval scaled – the <b>default</b> for all numeric (incl integer) columns of <code>x</code>, aka "I" in result Types, see <a href="#">dissimilarity.object</a>.</p> <p>Each component is a (character or numeric) vector, containing either the names or the numbers of the corresponding columns of <code>x</code>.</p> <p>Variables not mentioned in <code>type</code> are interpreted as usual, see argument <code>x</code>, and also 'default' above. Consequently, the default <code>type = list()</code> may often be sufficient.</p> |
| weights                      | <p>an optional numeric vector of length <math>p(=n\text{col}(x))</math>; to be used in "case 2" (mixed variables, or <code>metric = "gower"</code>), specifying a weight for each variable (<code>x[,k]</code>) instead of 1 in Gower's original formula.</p>  |
| warnBin, warnAsym, warnConst | <p>logicals indicating if the corresponding type checking warnings should be signalled (when found).</p>   |
| warnType                     | <p>logical indicating if <i>all</i> the type checking warnings should be active or not.</p>  |

## Details

The original version of `daisy` is fully described in chapter 1 of Kaufman and Rousseeuw (1990). Compared to [dist](#) whose input must be numeric variables, the main feature of `daisy` is its ability to handle other variable types as well (e.g. nominal, ordinal, (a)symmetric binary) even when different types occur in the same data set.

The handling of nominal, ordinal, and (a)symmetric binary data is achieved by using the general dissimilarity coefficient of Gower (1971). If `x` contains any columns of these data-types, both arguments `metric` and `stand` will be ignored and Gower's coefficient will be used as the metric. This can also be activated for purely numeric data by `metric = "gower"`. With that, each variable (column) is first standardized by dividing each entry by the range of the corresponding variable, after subtracting the minimum value; consequently the rescaled variable has range  $[0, 1]$ , exactly.

Note that setting the type to `symm` (symmetric binary) gives the same dissimilarities as using *nominal* (which is chosen for non-ordered factors) only when no missing values are present, and more efficiently.

Note that `daisy` signals a warning when 2-valued numerical variables do not have an explicit `type` specified, because the reference authors recommend to consider using `"asymm"`; the warning may be silenced by `warnBin = FALSE`.

In the `daisy` algorithm, missing values in a row of `x` are not included in the dissimilarities involving that row. There are two main cases,

1. If all variables are interval scaled (and `metric` is *not* `"gower"`), the metric is `"euclidean"`, and  $n_g$  is the number of columns in which neither row  $i$  and  $j$  have NAs, then the dissimilarity  $d(i,j)$  returned is  $\sqrt{p/n_g}$  ( $p = \text{ncol}(x)$ ) times the Euclidean distance between the two vectors of length  $n_g$  shortened to exclude NAs. The rule is similar for the `"manhattan"` metric, except that the coefficient is  $p/n_g$ . If  $n_g = 0$ , the dissimilarity is NA.
2. When some variables have a type other than interval scaled, or if `metric = "gower"` is specified, the dissimilarity between two rows is the weighted mean of the contributions of each variable. Specifically,

$$d_{ij} = d(i, j) = \frac{\sum_{k=1}^p w_k \delta_{ij}^{(k)} d_{ij}^{(k)}}{\sum_{k=1}^p w_k \delta_{ij}^{(k)}}.$$

In other words,  $d_{ij}$  is a weighted mean of  $d_{ij}^{(k)}$  with weights  $w_k \delta_{ij}^{(k)}$ , where  $w_k = \text{weights}[k]$ ,  $\delta_{ij}^{(k)}$  is 0 or 1, and  $d_{ij}^{(k)}$ , the  $k$ -th variable contribution to the total distance, is a distance between  $x[i, k]$  and  $x[j, k]$ , see below.

The 0-1 weight  $\delta_{ij}^{(k)}$  becomes zero when the variable  $x[, k]$  is missing in either or both rows ( $i$  and  $j$ ), or when the variable is asymmetric binary and both values are zero. In all other situations it is 1.

The contribution  $d_{ij}^{(k)}$  of a nominal or binary variable to the total dissimilarity is 0 if both values are equal, 1 otherwise. The contribution of other variables is the absolute difference of both values, divided by the total range of that variable. Note that “standard scoring” is applied to ordinal variables, i.e., they are replaced by their integer codes  $1 : K$ . Note that this is not the same as using their ranks (since there typically are ties).

As the individual contributions  $d_{ij}^{(k)}$  are in  $[0, 1]$ , the dissimilarity  $d_{ij}$  will remain in this range. If all weights  $w_k \delta_{ij}^{(k)}$  are zero, the dissimilarity is set to NA.

## Value

an object of class `"dissimilarity"` containing the dissimilarities among the rows of `x`. This is typically the input for the functions `pam`, `fanny`, `agnes` or `diana`. For more details, see [dissimilarity.object](#).

## Background

Dissimilarities are used as inputs to cluster analysis and multidimensional scaling. The choice of metric may have a large impact.

## Author(s)

Anja Struyf, Mia Hubert, and Peter and Rousseeuw, for the original version.

Martin Maechler improved the NA handling and type specification checking, and extended functionality to `metric = "gower"` and the optional `weights` argument.

## Examples

```
data(agriculture)
## Example 1 in ref:
## Dissimilarities using Euclidean metric and without standardization
d.agr <- daisy(agriculture, metric = "euclidean", stand = FALSE)
d.agr
as.matrix(d.agr)[,"DK"] # via as.matrix.dist(.)
## compare with
as.matrix(daisy(agriculture, metric = "gower"))

## Example 2 in reference, extended --- different ways of "mixed" / "gower":

example(flower) # -> data(flower) *and* provide 'flowerN'

summary(d0 <- daisy(flower)) # -> the first 3 {0,1} treated as *N*ominal
summary(dS123 <- daisy(flower, type = list(symm = 1:3))) # first 3 treated as *S*ymmetric
stopifnot(dS123 == d0) # i.e., *S*ymmetric <==> *N*ominal {for 2-level factor}
summary(dNS123 <- daisy(flowerN, type = list(symm = 1:3)))
stopifnot(dS123 == d0)
## by default, however ...
summary(dA123 <- daisy(flowerN)) # .. all 3 logicals treated *A*symmetric binary (w/ warn
summary(dA3 <- daisy(flower, type = list(asymm = 3)))
summary(dA13 <- daisy(flower, type = list(asymm = c(1, 3), ordratio = 7)))
## Mixing variable *names* and column numbers (failed in the past):
summary(df13 <- daisy(flower, type = list(asymm = c("V1", "V3"), symm = 2,
                                         ordratio = 7, logratio = 8)))

## If we'd treat the first 3 as simple {0,1}
Nflow <- flower
Nflow[,1:3] <- lapply(flower[,1:3], \(f) as.integer(as.character(f)))
summary(dN <- daisy(Nflow)) # w/ warning: treated binary .. 1:3 as interval
## Still, using Euclidean/Manhattan distance for {0-1} *is* identical to treating them as
stopifnot(dN == d0)
stopifnot(dN == daisy(Nflow, type = list(symm = 1:3))) # or as "S"
```

---

diana

*Divisive ANAlysis Clustering*

---

## Description

Computes a divisive hierarchical clustering of the dataset returning an object of class `diana`.

**Usage**

```
diana(x, diss = inherits(x, "dist"), metric = "euclidean", stand = FALSE,
      stop.at.k = FALSE,
      keep.diss = n < 100, keep.data = !diss, trace.lev = 0)
```

**Arguments**

|                                   |   |
|-----------------------------------|---|
| <code>x</code>                    | <p>data matrix or data frame, or dissimilarity matrix or object, depending on the value of the <code>diss</code> argument.</p> <p>In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) <i>are</i> allowed.</p> <p>In case of a dissimilarity matrix, <code>x</code> is typically the output of <code>daisy</code> or <code>dist</code>. Also a vector of length <math>n*(n-1)/2</math> is allowed (where <math>n</math> is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are <i>not</i> allowed.</p> |
| <code>diss</code>                 | <p>logical flag: if TRUE (default for <code>dist</code> or dissimilarity objects), then <code>x</code> will be considered as a dissimilarity matrix. If FALSE, then <code>x</code> will be considered as a matrix of observations by variables.</p>   |
| <code>metric</code>               | <p>character string specifying the metric to be used for calculating dissimilarities between observations.</p> <p>The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.</p>  |
| <code>stand</code>                | <p>logical; if true, the measurements in <code>x</code> are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.</p>  |
| <code>stop.at.k</code>            | <p>logical or integer, FALSE by default. Otherwise must be integer, say <math>k</math>, in <math>\{1, 2, \dots, n\}</math>, specifying that the <code>diana</code> algorithm should stop early. Non-default NOT YET IMPLEMENTED.</p>  |
| <code>keep.diss, keep.data</code> | <p>logicals indicating if the dissimilarities and/or input data <code>x</code> should be kept in the result. Setting these to FALSE can give much smaller results and hence even save memory allocation <i>time</i>.</p>  |
| <code>trace.lev</code>            | <p>integer specifying a trace level for printing diagnostics during the algorithm. Default 0 does not print anything; higher values print increasingly more.</p>  |

**Details**

`diana` is fully described in chapter 6 of Kaufman and Rousseeuw (1990). It is probably unique in computing a divisive hierarchy, whereas most other software for hierarchical clustering is agglomerative. Moreover, `diana` provides (a) the divisive coefficient (see `diana.object`) which measures the amount of clustering structure found; and (b) the banner, a novel graphical display (see `plot.diana`).

The `diana`-algorithm constructs a hierarchy of clusterings, starting with one large cluster containing all  $n$  observations. Clusters are divided until each cluster contains only a single observation. At each stage, the cluster with the largest diameter is selected. (The diameter of a cluster is the

largest dissimilarity between any two of its observations.)

To divide the selected cluster, the algorithm first looks for its most disparate observation (i.e., which has the largest average dissimilarity to the other observations of the selected cluster). This observation initiates the "splinter group". In subsequent steps, the algorithm reassigns observations that are closer to the "splinter group" than to the "old party". The result is a division of the selected cluster into two new clusters.

### Value

an object of class "diana" representing the clustering; this class has methods for the following generic functions: `print`, `summary`, `plot`.

Further, the class "diana" inherits from "twins". Therefore, the generic function `pltree` can be used on a diana object, and `as.hclust` and `as.dendrogram` methods are available.

A legitimate diana object is a list with the following components:

|                        |  |
|------------------------|--|
| <code>order</code>     | a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.  |
| <code>order.lab</code> | a vector similar to <code>order</code> , but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled.  |
| <code>height</code>    | a vector with the diameters of the clusters prior to splitting.  |
| <code>dc</code>        | the divisive coefficient, measuring the clustering structure of the dataset. For each observation $i$ , denote by $d(i)$ the diameter of the last cluster to which it belongs (before being split off as a single observation), divided by the diameter of the whole dataset. The <code>dc</code> is the average of all $1 - d(i)$ . It can also be seen as the average width (or the percentage filled) of the banner plot. Because <code>dc</code> grows with the number of observations, this measure should not be used to compare datasets of very different sizes. |
| <code>merge</code>     | an $(n-1)$ by 2 matrix, where $n$ is the number of observations. Row $i$ of <code>merge</code> describes the split at step $n-i$ of the clustering. If a number $j$ in row $r$ is negative, then the single observation $ j $ is split off at stage $n-r$ . If $j$ is positive, then the cluster that will be splitted at stage $n-j$ (described by row $j$ ), is split off at stage $n-r$ .   |
| <code>diss</code>      | an object of class "dissimilarity", representing the total dissimilarity matrix of the dataset.  |
| <code>data</code>      | a matrix containing the original or standardized measurements, depending on the <code>stand</code> option of the function <code>agnes</code> . If a dissimilarity matrix was given as input structure, then this component is not available.   |

### See Also

`agnes` also for background and references; `cutree` (and `as.hclust`) for grouping extraction; `daisy`, `dist`, `plot.diana`, `twins.object`.

### Examples

```
data(votes.repub)
dv <- diana(votes.repub, metric = "manhattan", stand = TRUE)
print(dv)
plot(dv)
```

```
## Cut into 2 groups:
dv2 <- cutree(as.hclust(dv), k = 2)
table(dv2) # 8 and 42 group members
rownames(votes.repub)[dv2 == 1]

## For two groups, does the metric matter ?
dv0 <- diana(votes.repub, stand = TRUE) # default: Euclidean
dv.2 <- cutree(as.hclust(dv0), k = 2)
table(dv2 == dv.2)## identical group assignments

str(as.dendrogram(dv0)) # {via as.dendrogram.twins() method}

data(agriculture)
## Plot similar to Figure 8 in ref
## Not run: plot(diana(agriculture), ask = TRUE)
```

---

dissimilarity.object

*Dissimilarity Matrix Object*

---

## Description

Objects of class "dissimilarity" representing the dissimilarity matrix of a dataset.

## Value

The dissimilarity matrix is symmetric, and hence its lower triangle (column wise) is represented as a vector to save storage space. If the object, is called `do`, and `n` the number of observations, i.e., `n <- attr(do, "Size")`, then for  $i < j \leq n$ , the dissimilarity between (row)  $i$  and  $j$  is `do[n*(i-1) - i*(i-1)/2 + j-i]`. The length of the vector is  $n*(n-1)/2$ , i.e., of order  $n^2$ .

"dissimilarity" objects also inherit from class `dist` and can use `dist` methods, in particular, `as.matrix`, such that  $d_{ij}$  from above is just `as.matrix(do)[i, j]`.

The object has the following attributes:

|            |  |
|------------|--|
| Size       | the number of observations in the dataset.   |
| Metric     | the metric used for calculating the dissimilarities. Possible values are "euclidean", "manhattan", "mixed" (if variables of different types were present in the dataset), and "unspecified".   |
| Labels     | optionally, contains the labels, if any, of the observations of the dataset.   |
| NA.message | optionally, if a dissimilarity could not be computed, because of too many missing values for some observations of the dataset.   |
| Types      | when a mixed metric was used, the types for each variable as one-letter codes, see also <code>type</code> in <code>daisy()</code> :<br>A: Asymmetric binary<br>S: Symmetric binary<br>N: Nominal (factor)<br>O: Ordinal (ordered factor)<br>I: Interval scaled, possibly after log transform "logratio" (numeric)<br>T: <code>raTio</code> treated as <code>ordered</code> |

## GENERATION

`daisy` returns this class of objects. Also the functions `pam`, `clara`, `fanny`, `agnes`, and `diana` return a dissimilarity object, as one component of their return objects.

## METHODS

The "dissimilarity" class has methods for the following generic functions: `print`, `summary`.

## See Also

`daisy`, `dist`, `pam`, `clara`, `fanny`, `agnes`, `diana`.

---

|               |  |
|---------------|--|
| ellipsoidhull | <i>Compute the Ellipsoid Hull or Spanning Ellipsoid of a Point Set</i> |
|---------------|--|

---

## Description

Compute the “ellipsoid hull” or “spanning ellipsoid”, i.e. the ellipsoid of minimal volume (‘area’ in 2D) such that all given points lie just inside or on the boundary of the ellipsoid.

## Usage

```
ellipsoidhull(x, tol=0.01, maxit=5000,
              ret.wt = FALSE, ret.sqdist = FALSE, ret.pr = FALSE)
## S3 method for class 'ellipsoid'
print(x, digits = max(1, getOption("digits") - 2), ...)
```

## Arguments

|   |  |
|---|--|
| <code>x</code>  | the $n$ $p$ -dimensional points as numeric $n \times p$ matrix.  |
| <code>tol</code>  | convergence tolerance for Titterton's algorithm. Setting this to much smaller values may drastically increase the number of iterations needed, and you may want to increase <code>maxit</code> as well.  |
| <code>maxit</code>  | integer giving the maximal number of iteration steps for the algorithm.  |
| <code>ret.wt</code> , <code>ret.sqdist</code> , <code>ret.pr</code> | logicals indicating if additional information should be returned, <code>ret.wt</code> specifying the <i>weights</i> , <code>ret.sqdist</code> the <i>squared distances</i> and <code>ret.pr</code> the final <b>probabilities</b> in the algorithms. |
| <code>digits</code> , ...   | the usual arguments to <code>print</code> methods.   |

## Details

The “spanning ellipsoid” algorithm is said to stem from Titterton(1976), in Pison et al (1999) who use it for `clusplot.default`.

The problem can be seen as a special case of the “Min.Vol.” ellipsoid of which a more flexible and general implementation is `cov.mve` in the MASS package.

**Value**

an object of class "ellipsoid", basically a [list](#) with several components, comprising at least

|                         |  |
|-------------------------|--|
| <code>cov</code>        | $p \times p$ covariance matrix description the ellipsoid.  |
| <code>loc</code>        | $p$ -dimensional location of the ellipsoid center.   |
| <code>d2</code>         | average squared radius. Further, $d2 = t^2$ , where $t$ is “the value of a t-statistic on the ellipse boundary” (from <a href="#">ellipse</a> in the <a href="#">ellipse</a> package), and hence, more usefully, <code>d2 = qchisq(alpha, df = p)</code> , where <code>alpha</code> is the confidence level for $p$ -variate normally distributed data with location and covariance <code>loc</code> and <code>cov</code> to lie inside the ellipsoid. |
| <code>wt</code>         | the vector of weights iff <code>ret.wt</code> was true.  |
| <code>sqdist</code>     | the vector of squared distances iff <code>ret.sqdist</code> was true.  |
| <code>prob</code>       | the vector of algorithm probabilities iff <code>ret.pr</code> was true.  |
| <code>it</code>         | number of iterations used.   |
| <code>tol, maxit</code> | just the input argument, see above.  |
| <code>eps</code>        | the achieved tolerance which is the maximal squared radius minus $p$ .   |
| <code>ierr</code>       | error code as from the algorithm; 0 means <i>ok</i> .  |
| <code>conv</code>       | logical indicating if the converged. This is defined as <code>it &lt; maxit &amp;&amp; ierr == 0</code> .  |

**Author(s)**

Martin Maechler did the present class implementation; Rousseeuw et al did the underlying original code.

**Examples**

```
x <- rnorm(100)
xy <- unname(cbind(x, rnorm(100) + 2*x + 10))
exy. <- ellipsoidhull(xy)
exy. # >> calling print.ellipsoid()

plot(xy, main = "ellipsoidhull(<Gauss data>) -- 'spanning points'")
lines(predict(exy.), col="blue")
points(rbind(exy.$loc), col = "red", cex = 3, pch = 13)
```

```

exy <- ellipsoidhull(xy, tol = 1e-7, ret.wt = TRUE, ret.sq = TRUE)
str(exy) # had small 'tol', hence many iterations
(ii <- which(zapsmall(exy $ wt) > 1e-6))
## --> only about 4 to 6 "spanning ellipsoid" points
round(exy$wt[ii], 3); sum(exy$wt[ii]) # weights summing to 1
points(xy[ii,], pch = 21, cex = 2,
       col="blue", bg = adjustcolor("blue", 0.25))

```

fanny

*Fuzzy Analysis Clustering*

## Description

Computes a fuzzy clustering of the data into  $k$  clusters.

## Usage

```

fanny(x, k, diss = inherits(x, "dist"), memb.exp = 2,
      metric = c("euclidean", "manhattan", "SqEuclidean"),
      stand = FALSE, iniMem.p = NULL, cluster.only = FALSE,
      keep.diss = !diss && !cluster.only && n < 100,
      keep.data = !diss && !cluster.only,
      maxit = 500, tol = 1e-15, trace.lev = 0)

```

## Arguments

- |                       |   |
|-----------------------|---|
| $x$                   | <p>data matrix or data frame, or dissimilarity matrix, depending on the value of the <code>diss</code> argument.</p> <p>In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.</p> <p>In case of a dissimilarity matrix, <math>x</math> is typically the output of <code>daisy</code> or <code>dist</code>. Also a vector of length <math>n*(n-1)/2</math> is allowed (where <math>n</math> is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.</p> |
| $k$                   | <p>integer giving the desired number of clusters. It is required that <math>0 &lt; k &lt; n/2</math> where <math>n</math> is the number of observations.</p>  |
| <code>diss</code>     | <p>logical flag: if TRUE (default for <code>dist</code> or <code>dissimilarity</code> objects), then <math>x</math> is assumed to be a dissimilarity matrix. If FALSE, then <math>x</math> is treated as a matrix of observations by variables.</p>   |
| <code>memb.exp</code> | <p>number <math>r</math> strictly larger than 1 specifying the <i>membership exponent</i> used in the fit criterion; see the ‘Details’ below. Default: 2 which used to be hardwired inside FANNY.</p>   |
| <code>metric</code>   | <p>character string specifying the metric to be used for calculating dissimilarities between observations. Options are "euclidean" (default), "manhattan", and "SqEuclidean". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences, and "SqEuclidean", the <i>squared</i> euclidean distances are sum-of-squares of differences. Using this last option is equivalent (but somewhat slower) to computing so called “fuzzy C-means”.</p> <p>If <math>x</math> is already a dissimilarity matrix, then this argument will be ignored.</p>  |

|                                   |   |
|-----------------------------------|---|
| <code>stand</code>                | logical; if true, the measurements in <code>x</code> are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored. |
| <code>iniMem.p</code>             | numeric $n \times k$ matrix or NULL (by default); can be used to specify a starting membership matrix, i.e., a matrix of non-negative numbers, each row summing to one.   |
| <code>cluster.only</code>         | logical; if true, no silhouette information will be computed and returned, see details.   |
| <code>keep.diss, keep.data</code> | logicals indicating if the dissimilarities and/or input data <code>x</code> should be kept in the result. Setting these to FALSE can give smaller results and hence also save memory allocation <i>time</i> .   |
| <code>maxit, tol</code>           | maximal number of iterations and default tolerance for convergence (relative convergence of the fit criterion) for the FANNY algorithm. The defaults <code>maxit</code> = 500 and <code>tol</code> = 1e-15 used to be hardwired inside the algorithm.   |
| <code>trace.lev</code>            | integer specifying a trace level for printing diagnostics during the C-internal algorithm. Default 0 does not print anything; higher values print increasingly more.  |

## Details

In a fuzzy clustering, each observation is “spread out” over the various clusters. Denote by  $u_{iv}$  the membership of observation  $i$  to cluster  $v$ .

The memberships are nonnegative, and for a fixed observation  $i$  they sum to 1. The particular method `fanny` stems from chapter 4 of Kaufman and Rousseeuw (1990) (see the references in `daisy`) and has been extended by Martin Maechler to allow user specified `memb.exp`, `iniMem.p`, `maxit`, `tol`, etc.

Fanny aims to minimize the objective function

$$\sum_{v=1}^k \frac{\sum_{i=1}^n \sum_{j=1}^n u_{iv}^r u_{jv}^r d(i, j)}{2 \sum_{j=1}^n u_{jv}^r}$$

where  $n$  is the number of observations,  $k$  is the number of clusters,  $r$  is the membership exponent `memb.exp` and  $d(i, j)$  is the dissimilarity between observations  $i$  and  $j$ .

Note that  $r \rightarrow 1$  gives increasingly crisper clusterings whereas  $r \rightarrow \infty$  leads to complete fuzzyness. K&R(1990), p.191 note that values too close to 1 can lead to slow convergence. Further note that even the default,  $r = 2$  can lead to complete fuzzyness, i.e., memberships  $u_{iv} \equiv 1/k$ . In that case a warning is signalled and the user is advised to chose a smaller `memb.exp` ( $= r$ ).

Compared to other fuzzy clustering methods, `fanny` has the following features: (a) it also accepts a dissimilarity matrix; (b) it is more robust to the `spherical cluster` assumption; (c) it provides a novel graphical display, the silhouette plot (see `plot.partition`).

## Value

an object of class "fanny" representing the clustering. See `fanny.object` for details.

## See Also

`agnes` for background and references; `fanny.object`, `partition.object`, `plot.partition`, `daisy`, `dist`.

Examples

```
## generate 10+15 objects in two clusters, plus 3 objects lying
## between those clusters.
x <- rbind(cbind(rnorm(10, 0, 0.5), rnorm(10, 0, 0.5)),
           cbind(rnorm(15, 5, 0.5), rnorm(15, 5, 0.5)),
           cbind(rnorm( 3,3.2,0.5), rnorm( 3,3.2,0.5)))
fannyx <- fanny(x, 2)
## Note that observations 26:28 are "fuzzy" (closer to # 2):
fannyx
summary(fannyx)
plot(fannyx)

(fan.x.15 <- fanny(x, 2, memb.exp = 1.5)) # 'crispier' for obs. 26:28
(fanny(x, 2, memb.exp = 3))              # more fuzzy in general

data(ruspini)
f4 <- fanny(ruspini, 4)
stopifnot(rle(f4$clustering)$lengths == c(20,23,17,15))
plot(f4, which = 1)
## Plot similar to Figure 6 in Stryuf et al (1996)
plot(fanny(ruspini, 5))
```

---

|              |                                      |
|--------------|--------------------------------------|
| fanny.object | <i>Fuzzy Analysis (FANNY) Object</i> |
|--------------|--------------------------------------|

---

Description

The objects of class "fanny" represent a fuzzy clustering of a dataset.

Value

A legitimate fanny object is a list with the following components:

|             |   |
|-------------|---|
| membership  | matrix containing the memberships for each pair consisting of an observation and a cluster.   |
| memb.exp    | the membership exponent used in the fitting criterion.  |
| coeff       | Dunn's partition coefficient $F(k)$ of the clustering, where $k$ is the number of clusters. $F(k)$ is the sum of all <i>squared</i> membership coefficients, divided by the number of observations. Its value is between $1/k$ and 1.<br>The normalized form of the coefficient is also given. It is defined as $(F(k) - 1/k)/(1 - 1/k)$ , and ranges between 0 and 1. A low value of Dunn's coefficient indicates a very fuzzy clustering, whereas a value close to 1 indicates a near-crisp clustering. |
| clustering  | the clustering vector of the nearest crisp clustering, see <a href="#">partition.object</a> .   |
| k.crisp     | integer ( $\leq k$ ) giving the number of <i>crisp</i> clusters; can be less than $k$ , where it's recommended to decrease <code>memb.exp</code> .  |
| objective   | named vector containing the minimal value of the objective function reached by the FANNY algorithm and the relative convergence tolerance <code>tol</code> used.  |
| convergence | named vector with <code>iterations</code> , the number of iterations needed and <code>converged</code> indicating if the algorithm converged (in <code>maxit</code> iterations within convergence tolerance <code>tol</code> ).   |

|         |  |
|---------|--|
| diss    | an object of class "dissimilarity", see <a href="#">partition.object</a> .                               |
| call    | generating call, see <a href="#">partition.object</a> .  |
| silinfo | list with silhouette information of the nearest crisp clustering, see <a href="#">partition.object</a> . |
| data    | matrix, possibly standardized, or NULL, see <a href="#">partition.object</a> .                           |

**GENERATION**

These objects are returned from [fanny](#).

**METHODS**

The "fanny" class has methods for the following generic functions: print, summary.

**INHERITANCE**

The class "fanny" inherits from "partition". Therefore, the generic functions plot and clusplot can be used on a fanny object.

**See Also**

[fanny](#), [print.fanny](#), [dissimilarity.object](#), [partition.object](#), [plot.partition](#).

---

|        |                               |
|--------|-------------------------------|
| flower | <i>Flower Characteristics</i> |
|--------|-------------------------------|

---

**Description**

8 characteristics for 18 popular flowers.

**Usage**

`data(flower)`

**Format**

A data frame with 18 observations on 8 variables:

|           |         |            |
|-----------|---------|------------|
| [ , "V1"] | factor  | winters    |
| [ , "V2"] | factor  | shadow     |
| [ , "V3"] | factor  | tubers     |
| [ , "V4"] | factor  | color      |
| [ , "V5"] | ordered | soil       |
| [ , "V6"] | ordered | preference |
| [ , "V7"] | numeric | height     |
| [ , "V8"] | numeric | distance   |

**V1** winters, is binary and indicates whether the plant may be left in the garden when it freezes.

**V2** shadow, is binary and shows whether the plant needs to stand in the shadow.

**V3** tubers, is asymmetric binary and distinguishes between plants with tubers and plants that grow

in any other way.

**V4** color, is nominal and specifies the flower's color (1 = white, 2 = yellow, 3 = pink, 4 = red, 5 = blue).

**V5** soil, is ordinal and indicates whether the plant grows in dry (1), normal (2), or wet (3) soil.

**V6** preference, is ordinal and gives someone's preference ranking going from 1 to 18.

**V7** height, is interval scaled, the plant's height in centimeters.

**V8** distance, is interval scaled, the distance in centimeters that should be left between the plants.

## References

Struyf, Hubert and Rousseeuw (1996), see [agnes](#).

## Examples

```
data(flower)
str(flower) # factors, ordered, numeric

## "Nicer" version (less numeric more self explainable) of 'flower':
flowerN <- flower
colnames(flowerN) <- c("winters", "shadow", "tubers", "color",
                      "soil", "preference", "height", "distance")
for(j in 1:3) flowerN[,j] <- (flowerN[,j] == "1")
levels(flowerN$color) <- c("1" = "white", "2" = "yellow", "3" = "pink",
                          "4" = "red", "5" = "blue")[levels(flowerN$color)]
levels(flowerN$soil) <- c("1" = "dry", "2" = "normal", "3" = "wet")[levels(flowerN$soil)]
flowerN

## ==> example(daisy) on how it is used
```

---

lower.to.upper.tri.inds

*Permute Indices for Triangular Matrices*

---

## Description

Compute index vectors for extracting or reordering of lower or upper triangular matrices that are stored as contiguous vectors.

## Usage

```
lower.to.upper.tri.inds(n)
upper.to.lower.tri.inds(n)
```

## Arguments

**n** integer larger than 1.

## Value

integer vector containing a permutation of  $1:N$  where  $N = n(n-1)/2$ .

**See Also**

[upper.tri](#), [lower.tri](#) with a related purpose.

**Examples**

```
m5 <- matrix(NA, 5, 5)
m <- m5; m[lower.tri(m)] <- upper.to.lower.tri.inds(5); m
m <- m5; m[upper.tri(m)] <- lower.to.upper.tri.inds(5); m

stopifnot(lower.to.upper.tri.inds(2) == 1,
           lower.to.upper.tri.inds(3) == 1:3,
           upper.to.lower.tri.inds(3) == 1:3,
           sort(upper.to.lower.tri.inds(5)) == 1:10,
           sort(lower.to.upper.tri.inds(6)) == 1:15)
```

---

medoids

---

*Compute pam-consistent Medoids from Clustering*

---

**Description**

Given a data matrix or dissimilarity  $x$  for say  $n$  observational units and a clustering, compute the [pam\(\)](#)-consistent medoids.

**Usage**

```
medoids(x, clustering, diss = inherits(x, "dist"), USE.NAMES = FALSE, ...)
```

**Arguments**

|                         |  |
|-------------------------|--|
| <code>x</code>          | Either a data matrix or data frame, or dissimilarity matrix or object, see also <a href="#">pam</a> .  |
| <code>clustering</code> | an integer vector of length $n$ , the number of observations, giving for each observation the number ('id') of the cluster to which it belongs. In other words, <code>clustering</code> has values from $1:k$ where $k$ is the number of clusters, see also <a href="#">partition.object</a> and <a href="#">cutree()</a> , for examples where such clustering vectors are computed. |
| <code>diss</code>       | see also <a href="#">pam</a> .   |
| <code>USE.NAMES</code>  | a logical, typical false, passed to the <a href="#">vapply()</a> call computing the medoids.   |
| <code>...</code>        | optional further argument passed to <a href="#">pam(xj, k=1, ...)</a> , notably <code>metric</code> , or <code>variant="f_5"</code> to use a faster algorithm, or <code>trace.lev = k</code> .   |

**Value**

a numeric vector of length

**Author(s)**

Martin Maechler, after being asked how [pam\(\)](#) could be used instead of [kmeans\(\)](#), starting from a previous clustering.

## See Also

[pam](#), [kmeans](#). Further, [cutree\(\)](#) and [agnes](#) (or [hclust](#)).

## Examples

```
## From example(agnes):
data(votes.repub)
agn1 <- agnes(votes.repub, metric = "manhattan", stand = TRUE)
agn2 <- agnes(daisy(votes.repub), diss = TRUE, method = "complete")
agnS <- agnes(votes.repub, method = "flexible", par.meth = 0.625)

for(k in 2:11) {
  print(table(cl.k <- cutree(agnS, k=k)))
  stopifnot(length(cl.k) == nrow(votes.repub), 1 <= cl.k, cl.k <= k, table(cl.k) >= 2)
  m.k <- medoids(votes.repub, cl.k)
  cat("k =", k, "; sort(medoids) = "; dput(sort(m.k), control={})
}
```

---

mona

*MONothetic Analysis Clustering of Binary Variables*

---

## Description

Returns a list representing a divisive hierarchical clustering of a dataset with binary variables only.

## Usage

```
mona(x, trace.lev = 0)
```

## Arguments

|                        |   |
|------------------------|---|
| <code>x</code>         | data matrix or data frame in which each row corresponds to an observation, and each column corresponds to a variable. All variables must be binary. A limited number of missing values (NAs) is allowed. Every observation must have at least one value different from <a href="#">NA</a> . No variable should have half of its values missing. There must be at least one variable which has no missing values. A variable with all its non-missing values identical is not allowed. |
| <code>trace.lev</code> | logical or integer indicating if (and how much) the algorithm should produce progress output.   |

## Details

`mona` is fully described in chapter 7 of Kaufman and Rousseeuw (1990). It is “monothetic” in the sense that each division is based on a single (well-chosen) variable, whereas most other hierarchical methods (including `agnes` and `diana`) are “polythetic”, i.e. they use all variables together.

The `mona`-algorithm constructs a hierarchy of clusterings, starting with one large cluster. Clusters are divided until all observations in the same cluster have identical values for all variables.

At each stage, all clusters are divided according to the values of one variable. A cluster is divided into one cluster with all observations having value 1 for that variable, and another cluster with all observations having value 0 for that variable.

The variable used for splitting a cluster is the variable with the maximal total association to the other variables, according to the observations in the cluster to be splitted. The association between variables  $f$  and  $g$  is given by  $a(f,g)*d(f,g) - b(f,g)*c(f,g)$ , where  $a(f,g)$ ,  $b(f,g)$ ,  $c(f,g)$ , and  $d(f,g)$  are the numbers in the contingency table of  $f$  and  $g$ . [That is,  $a(f,g)$  (resp.  $d(f,g)$ ) is the number of observations for which  $f$  and  $g$  both have value 0 (resp. value 1);  $b(f,g)$  (resp.  $c(f,g)$ ) is the number of observations for which  $f$  has value 0 (resp. 1) and  $g$  has value 1 (resp. 0).] The total association of a variable  $f$  is the sum of its associations to all variables.

## Value

an object of class "mona" representing the clustering. See [mona.object](#) for details.

## Missing Values (NAs)

The mona-algorithm requires “pure” 0-1 values. However, `mona(x)` allows  $x$  to contain (not too many) NAs. In a preliminary step, these are “imputed”, i.e., all missing values are filled in. To do this, the same measure of association between variables is used as in the algorithm. When variable  $f$  has missing values, the variable  $g$  with the largest absolute association to  $f$  is looked up. When the association between  $f$  and  $g$  is positive, any missing value of  $f$  is replaced by the value of  $g$  for the same observation. If the association between  $f$  and  $g$  is negative, then any missing value of  $f$  is replaced by the value of  $1-g$  for the same observation.

## Note

In **cluster** versions before 2.0.6, the algorithm entered an infinite loop in the boundary case of one variable, i.e., `ncol(x) == 1`, which currently signals an error (because the algorithm now in C, has not correctly taken account of this special case).

## See Also

[agnes](#) for background and references; [mona.object](#), [plot.mona](#).

## Examples

```
data(animals)
ma <- mona(animals)
ma
## Plot similar to Figure 10 in Struyf et al (1996)
plot(ma)

## One place to see if/how error messages are *translated* (to 'de' / 'pl'):
ani.NA <- animals; ani.NA[4,] <- NA
aniNA <- within(animals, { end[2:9] <- NA })
aniN2 <- animals; aniN2[cbind(1:6, c(3, 1, 4:6, 2))] <- NA
ani.non2 <- within(animals, end[7] <- 3 )
ani.idNA <- within(animals, end[!is.na(end)] <- 1 )
try( mona(ani.NA) ) ## error: .. object with all values missing
try( mona(aniNA) ) ## error: .. more than half missing values
try( mona(aniN2) ) ## error: all have at least one missing
try( mona(ani.non2) ) ## error: all must be binary
try( mona(ani.idNA) ) ## error: ditto
```

---

|                          |  |
|--------------------------|--|
| <code>mona.object</code> | <i>Monothetic Analysis (MONA) Object</i> |
|--------------------------|--|

---

**Description**

The objects of class "mona" represent the divisive hierarchical clustering of a dataset with only binary variables (measurements). This class of objects is returned from [mona](#).

**Value**

A legitimate `mona` object is a list with the following components:

|                        |   |
|------------------------|---|
| <code>data</code>      | matrix with the same dimensions as the original data matrix, but with factors coded as 0 and 1, and all missing values replaced.  |
| <code>order</code>     | a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.                                   |
| <code>order.lab</code> | a vector similar to <code>order</code> , but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled. |
| <code>variable</code>  | vector of length <code>n-1</code> where <code>n</code> is the number of observations, specifying the variables used to separate the observations of <code>order</code> .                |
| <code>step</code>      | vector of length <code>n-1</code> where <code>n</code> is the number of observations, specifying the separation steps at which the observations of <code>order</code> are separated.    |

**METHODS**

The "mona" class has methods for the following generic functions: `print`, `summary`, `plot`.

**See Also**

[mona](#) for examples etc, [plot.mona](#).

---

|                  |                                    |
|------------------|------------------------------------|
| <code>pam</code> | <i>Partitioning Around Medoids</i> |
|------------------|------------------------------------|

---

**Description**

Partitioning (clustering) of the data into `k` clusters “around medoids”, a more robust version of K-means.

**Usage**

```
pam(x, k, diss = inherits(x, "dist"),
    metric = c("euclidean", "manhattan"),
    medoids = if(is.numeric(nstart)) "random",
    nstart = if(variant == "faster") 1 else NA,
    stand = FALSE, cluster.only = FALSE,
    do.swap = TRUE,
    keep.diss = !diss && !cluster.only && n < 100,
```

```
keep.data = !diss && !cluster.only,
variant = c("original", "o_1", "o_2", "f_3", "f_4", "f_5", "faster"),
pamonce = FALSE, trace.lev = 0)
```

## Arguments

|                                   |  |
|-----------------------------------|--|
| <code>x</code>                    | <p>data matrix or data frame, or dissimilarity matrix or object, depending on the value of the <code>diss</code> argument.</p> <p>In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric (or logical). Missing values (NAs) <i>are</i> allowed—as long as every pair of observations has at least one case not missing.</p> <p>In case of a dissimilarity matrix, <code>x</code> is typically the output of <code>daisy</code> or <code>dist</code>. Also a vector of length <math>n*(n-1)/2</math> is allowed (where <math>n</math> is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are <i>not</i> allowed.</p> |
| <code>k</code>                    | positive integer specifying the number of clusters, less than the number of observations.  |
| <code>diss</code>                 | logical flag: if TRUE (default for <code>dist</code> or <code>dissimilarity</code> objects), then <code>x</code> will be considered as a dissimilarity matrix. If FALSE, then <code>x</code> will be considered as a matrix of observations by variables.  |
| <code>metric</code>               | <p>character string specifying the metric to be used for calculating dissimilarities between observations.</p> <p>The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.</p>   |
| <code>medoids</code>              | NULL (default) or length- <code>k</code> vector of integer indices (in $1:n$ ) specifying initial medoids instead of using the ‘ <i>build</i> ’ algorithm.   |
| <code>nstart</code>               | used only when <code>medoids = "random"</code> : specifies the <i>number</i> of random “starts”; this argument corresponds to the one of <code>kmeans()</code> (from R’s package <b>stats</b> ).   |
| <code>stand</code>                | logical; if true, the measurements in <code>x</code> are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.  |
| <code>cluster.only</code>         | logical; if true, only the clustering will be computed and returned, see details.  |
| <code>do.swap</code>              | logical indicating if the <b>swap</b> phase should happen. The default, TRUE, correspond to the original algorithm. On the other hand, the <b>swap</b> phase is much more computer intensive than the <b>build</b> one for large $n$ , so can be skipped by <code>do.swap = FALSE</code> .   |
| <code>keep.diss, keep.data</code> | logicals indicating if the dissimilarities and/or input data <code>x</code> should be kept in the result. Setting these to FALSE can give much smaller results and hence even save memory allocation <i>time</i> .   |
| <code>pamonce</code>              | logical or integer in $0:6$ specifying algorithmic short cuts as proposed by Reynolds et al. (2006), and Schubert and Rousseeuw (2019, 2021) see below.  |

|                        |  |
|------------------------|--|
| <code>variant</code>   | a <a href="#">character</a> string denoting the variant of PAM algorithm to use; a more self-documenting version of <code>pamonce</code> which should be used preferably; note that "faster" not only uses <code>pamonce = 6</code> but also <code>nstart = 1</code> and hence <code>medoids = "random"</code> by default. |
| <code>trace.lev</code> | integer specifying a trace level for printing diagnostics during the build and swap phase of the algorithm. Default 0 does not print anything; higher values print increasingly more.  |

## Details

The basic `pam` algorithm is fully described in chapter 2 of Kaufman and Rousseeuw(1990). Compared to the `k-means` approach in `kmeans`, the function `pam` has the following features: (a) it also accepts a dissimilarity matrix; (b) it is more robust because it minimizes a sum of dissimilarities instead of a sum of squared euclidean distances; (c) it provides a novel graphical display, the silhouette plot (see `plot.partition`) (d) it allows to select the number of clusters using `mean(silhouette(pr)[, "sil_width"])` on the result `pr <- pam(. .)`, or directly its component `pr$silinfo$avg.width`, see also [pam.object](#).

When `cluster.only` is `true`, the result is simply a (possibly named) integer vector specifying the clustering, i.e.,

`pam(x, k, cluster.only=TRUE)` is the same as  
`pam(x, k)$clustering` but computed more efficiently.

The `pam`-algorithm is based on the search for `k` representative objects or medoids among the observations of the dataset. These observations should represent the structure of the data. After finding a set of `k` medoids, `k` clusters are constructed by assigning each observation to the nearest medoid. The goal is to find `k` representative objects which minimize the sum of the dissimilarities of the observations to their closest representative object.

By default, when `medoids` are not specified, the algorithm first looks for a good initial set of medoids (this is called the **build** phase). Then it finds a local minimum for the objective function, that is, a solution such that there is no single switch of an observation with a medoid (i.e. a 'swap') that will decrease the objective (this is called the **swap** phase).

When the `medoids` are specified (or randomly generated), their order does *not* matter; in general, the algorithms have been designed to not depend on the order of the observations.

The `pamonce` option, new in cluster 1.14.2 (Jan. 2012), has been proposed by Matthias Studer, University of Geneva, based on the findings by Reynolds et al. (2006) and was extended by Erich Schubert, TU Dortmund, with the FastPAM optimizations.

The default `FALSE` (or integer 0) corresponds to the original "swap" algorithm, whereas `pamonce = 1` (or `TRUE`), corresponds to the first proposal .... and `pamonce = 2` additionally implements the second proposal as well.

The key ideas of 'FastPAM' (Schubert and Rousseeuw, 2019) are implemented except for the linear approximate build as follows:

`pamonce = 3`: reduces the runtime by a factor of  $O(k)$  by exploiting that points cannot be closest to all current medoids at the same time.

`pamonce = 4`: additionally allows executing multiple swaps per iteration, usually reducing the number of iterations.

`pamonce = 5`: adds minor optimizations copied from the `pamonce = 2` approach, and is expected to be the fastest of the 'FastPam' variants included.

'FasterPAM' (Schubert and Rousseeuw, 2021) is implemented via

`pamonce = 6`: execute each swap which improves results immediately, and hence typically multiple swaps per iteration; this swapping algorithm runs in  $O(n^2)$  rather than  $O(n(n-k)k)$  time which is much faster for all but small  $k$ .

In addition, ‘FasterPAM’ uses *random* initialization of the medoids (instead of the ‘*build*’ phase) to avoid the  $O(n^2k)$  initialization cost of the build algorithm. In particular for large  $k$ , this yields a much faster algorithm, while preserving a similar result quality.

One may decide to use *repeated* random initialization by setting `nstart > 1`.

### Value

an object of class "pam" representing the clustering. See `?pam.object` for details.

### Note

For large datasets, `pam` may need too much memory or too much computation time since both are  $O(n^2)$ . Then, `clara()` is preferable, see its documentation.

There is hard limit currently,  $n \leq 65536$ , at  $2^{16}$  because for larger  $n$ ,  $n(n-1)/2$  is larger than the maximal integer (`.Machine$integer.max = 231 - 1`).

### Author(s)

Kaufman and Rousseeuw’s original Fortran code was translated to C and augmented in several ways, e.g. to allow `cluster.only=TRUE` or `do.swap=FALSE`, by Martin Maechler.  
Matthias Studer, Univ.Geneva provided the `pamonce` (1 and 2) implementation.  
Erich Schubert, TU Dortmund contributed the `pamonce` (3 to 6) implementation.

### Examples

```
## generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),
           cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
pamx <- pam(x, 2)
pamx # Medoids: '7' and '25' ...
summary(pamx)
plot(pamx)
## use obs. 1 & 16 as starting medoids -- same result (typically)
(p2m <- pam(x, 2, medoids = c(1,16)))
```

```
## no _build_ *and* no _swap_ phase: just cluster all obs. around (1, 16):
p2.s <- pam(x, 2, medoids = c(1,16), do.swap = FALSE)
p2.s

p3m <- pam(x, 3, trace = 2)
## rather stupid initial medoids:
(p3m. <- pam(x, 3, medoids = 3:1, trace = 1))

pam(daisy(x, metric = "manhattan"), 2, diss = TRUE)

data(ruspini)
## Plot similar to Figure 4 in Stryuf et al (1996)
## Not run: plot(pam(ruspini, 4), ask = TRUE)
```

pam.object

*Partitioning Around Medoids (PAM) Object*

## Description

The objects of class "pam" represent a partitioning of a dataset into clusters.

## Value

A legitimate pam object is a [list](#) with the following components:

|            |  |
|------------|--|
| medoids    | the medoids or representative objects of the clusters. If a dissimilarity matrix was given as input to pam, then a vector of numbers or labels of observations is given, else medoids is a <a href="#">matrix</a> with in each row the coordinates of one medoid.  |
| id.med     | integer vector of <i>indices</i> giving the medoid observation numbers.  |
| clustering | the clustering vector, see <a href="#">partition.object</a> .  |
| objective  | the objective function after the first and second step of the pam algorithm.   |
| isolation  | vector with length equal to the number of clusters, specifying which clusters are isolated clusters (L- or L*-clusters) and which clusters are not isolated. A cluster is an L*-cluster iff its diameter is smaller than its separation. A cluster is an L-cluster iff for each observation i the maximal dissimilarity between i and any other observation of the cluster is smaller than the minimal dissimilarity between i and any observation of another cluster. Clearly each L*-cluster is also an L-cluster. |
| clusinfo   | matrix, each row gives numerical information for one cluster. These are the cardinality of the cluster (number of observations), the maximal and average dissimilarity between the observations in the cluster and the cluster's medoid, the diameter of the cluster (maximal dissimilarity between two observations of the cluster), and the separation of the cluster (minimal dissimilarity between an observation of the cluster and an observation of another cluster).   |
| silinfo    | list with silhouette width information, see <a href="#">partition.object</a> .   |
| diss       | dissimilarity (maybe NULL), see <a href="#">partition.object</a> .   |
| call       | generating call, see <a href="#">partition.object</a> .  |
| data       | (possiblyly standardized) see <a href="#">partition.object</a> .   |

## GENERATION

These objects are returned from [pam](#).

## METHODS

The "pam" class has methods for the following generic functions: `print`, `summary`.

## INHERITANCE

The class "pam" inherits from "partition". Therefore, the generic functions `plot` and `clusplot` can be used on a pam object.

## See Also

[pam](#), [dissimilarity.object](#), [partition.object](#), [plot.partition](#).

## Examples

```
## Use the silhouette widths for assessing the best number of clusters,
## following a one-dimensional example from Christian Hennig :
##
x <- c(rnorm(50), rnorm(50,mean=5), rnorm(30,mean=15))
asw <- numeric(20)
## Note that "k=1" won't work!
for (k in 2:20)
  asw[k] <- pam(x, k) $ silinfo $ avg.width
k.best <- which.max(asw)
cat("silhouette-optimal number of clusters:", k.best, "\n")

plot(1:20, asw, type= "h", main = "pam() clustering assessment",
     xlab= "k (# clusters)", ylab = "average silhouette width")
axis(1, k.best, paste("best",k.best,sep="\n"), col = "red", col.axis = "red")
```

---

|                  |                            |
|------------------|----------------------------|
| partition.object | <i>Partitioning Object</i> |
|------------------|----------------------------|

---

## Description

The objects of class "partition" represent a partitioning of a dataset into clusters.

## Value

a "partition" object is a list with the following (and typically more) components:

|                         |   |
|-------------------------|---|
| <code>clustering</code> | the clustering vector. An integer vector of length $n$ , the number of observations, giving for each observation the number ('id') of the cluster to which it belongs.                            |
| <code>call</code>       | the matched <a href="#">call</a> generating the object.   |
| <code>silinfo</code>    | a list with all <i>silhouette</i> information, only available when the number of clusters is non-trivial, i.e., $1 < k < n$ and then has the following components, see <a href="#">silhouette</a> |

|           |  |
|-----------|--|
|           | <p><b>widths</b> an (n x 3) matrix, as returned by <code>silhouette()</code>, with for each observation <i>i</i> the cluster to which <i>i</i> belongs, as well as the neighbor cluster of <i>i</i> (the cluster, not containing <i>i</i>, for which the average dissimilarity between its observations and <i>i</i> is minimal), and the silhouette width <math>s(i)</math> of the observation.</p> <p><b>clus.avg.widths</b> the average silhouette width per cluster.</p> <p><b>avg.width</b> the average silhouette width for the dataset, i.e., simply the average of <math>s(i)</math> over all observations <i>i</i>.</p> <p>This information is also needed to construct a <i>silhouette plot</i> of the clustering, see <code>plot.partition</code>.</p> <p>Note that <code>avg.width</code> can be maximized over different clusterings (e.g. with varying number of clusters) to choose an <i>optimal</i> clustering.</p> |
| objective | value of criterion maximized during the partitioning algorithm, may more than one entry for different stages.  |
| diss      | an object of class "dissimilarity", representing the total dissimilarity matrix of the dataset (or relevant subset, e.g. for <code>clara</code> ).   |
| data      | a matrix containing the original or standardized data. This might be missing to save memory or when a dissimilarity matrix was given as input structure to the clustering method.  |

GENERATION

These objects are returned from `pam`, `clara` or `fanny`.

METHODS

The "partition" class has a method for the following generic functions: `plot`, `clusplot`.

INHERITANCE

The following classes inherit from class "partition": "pam", "clara" and "fanny".  
See `pam.object`, `clara.object` and `fanny.object` for details.

See Also

`pam`, `clara`, `fanny`.

|-------------|----------------------------------|
| plantTraits | <i>Plant Species Traits Data</i> |
|-------------|----------------------------------|

---

Description

This dataset constitutes a description of 136 plant species according to biological attributes (morphological or reproductive)

Usage

`data(plantTraits)`

**Format**

A data frame with 136 observations on the following 31 variables.

pdias Diaspore mass (mg)  
 longindex Seed bank longevity  
 durflow Flowering duration  
 height Plant height, an ordered factor with levels 1 < 2 < ... < 8.  
 begflow Time of first flowering, an ordered factor with levels 1 < 2 < 3 < 4 < 5 < 6 < 7 < 8 < 9  
 mycor Mycorrhizas, an ordered factor with levels 0never < 1 sometimes < 2always  
 vegaer aerial vegetative propagation, an ordered factor with levels 0never < 1 present but limited < 2important.  
 vegsout underground vegetative propagation, an ordered factor with 3 levels identical to vegaer above.  
 autopoll selfing pollination, an ordered factor with levels 0never < 1rare < 2 often < the rule3  
 insects insect pollination, an ordered factor with 5 levels 0 < ... < 4.  
 wind wind pollination, an ordered factor with 5 levels 0 < ... < 4.  
 lign a binary factor with levels 0:1, indicating if plant is woody.  
 piq a binary factor indicating if plant is thorny.  
 ros a binary factor indicating if plant is rosette.  
 semiros semi-rosette plant, a binary factor (0: no; 1: yes).  
 leafy leafy plant, a binary factor.  
 suman summer annual, a binary factor.  
 winan winter annual, a binary factor.  
 monocarp monocarpic perennial, a binary factor.  
 polycarp polycarpic perennial, a binary factor.  
 seasaes seasonal aestival leaves, a binary factor.  
 seashiv seasonal hibernal leaves, a binary factor.  
 seasver seasonal vernal leaves, a binary factor.  
 everalw leaves always evergreen, a binary factor.  
 everparti leaves partially evergreen, a binary factor.  
 elaio fruits with an elaiosome (dispersed by ants), a binary factor.  
 endozoo endozoochorous fruits, a binary factor.  
 epizoo epizoochorous fruits, a binary factor.  
 aquat aquatic dispersal fruits, a binary factor.  
 windgl wind dispersed fruits, a binary factor.  
 unsp unspecialized mechanism of seed dispersal, a binary factor.

**Details**

Most of factor attributes are not disjunctive. For example, a plant can be usually pollinated by insects but sometimes self-pollination can occurred.

plot(cmdsdai.b[, 1:2], asp = 1, col = cutree6)
```

---

plot.agnes

*Plots of an Agglomerative Hierarchical Clustering*

---

## Description

Creates plots for visualizing an `agnes` object.

## Usage

```
## S3 method for class 'agnes'
plot(x, ask = FALSE, which.plots = NULL, main = NULL,
      sub = paste("Agglomerative Coefficient = ", round(x$ac, digits = 2)),
      adj = 0, nmax.lab = 35, max.strlen = 5, xax.pretty = TRUE, ...)
```

## Arguments

|                          |  |
|--------------------------|--|
| <code>x</code>           | an object of class "agnes", typically created by <code>agnes()</code> .  |
| <code>ask</code>         | logical; if true and <code>which.plots</code> is NULL, <code>plot.agnes</code> operates in interactive mode, via <code>menu</code> .   |
| <code>which.plots</code> | integer vector or NULL (default), the latter producing both plots. Otherwise, <code>which.plots</code> must contain integers of 1 for a <i>banner</i> plot or 2 for a dendrogram or “clustering tree”. |
| <code>main, sub</code>   | main and sub title for the plot, with convenient defaults. See documentation for these arguments in <code>plot.default</code> .  |
| <code>adj</code>         | for label adjustment in <code>bannerplot()</code> .  |

|                         |  |
|-------------------------|--|
| <code>nmax.lab</code>   | integer indicating the number of labels which is considered too large for single-name labelling the banner plot.   |
| <code>max.strlen</code> | positive integer giving the length to which strings are truncated in banner plot labeling.   |
| <code>xax.pretty</code> | logical or integer indicating if <code>pretty(*, n = xax.pretty)</code> should be used for the x axis. <code>xax.pretty = FALSE</code> is for back compatibility.                      |
| <code>...</code>        | graphical parameters (see <code>par</code> ) may also be supplied and are passed to <code>bannerplot()</code> or <code>pltree()</code> (see <code>pltree.twins</code> ), respectively. |

## Details

When `ask = TRUE`, rather than producing each plot sequentially, `plot.agnes` displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted one must set `par(ask = TRUE)` before invoking the plot command.

The banner displays the hierarchy of clusters, and is equivalent to a tree. See Rousseeuw (1986) or chapter 5 of Kaufman and Rousseeuw (1990). The banner plots distances at which observations and clusters are merged. The observations are listed in the order found by the `agnes` algorithm, and the numbers in the `height` vector are represented as bars between the observations.

The leaves of the clustering tree are the original observations. Two branches come together at the distance between the two clusters being merged.

For more customization of the plots, rather call `bannerplot` and `pltree()`, i.e., its method `pltree.twins`, respectively.

directly with corresponding arguments, e.g., `xlab` or `ylab`.

## Side Effects

Appropriate plots are produced on the current graphics device. This can be one or both of the following choices:

Banner  
Clustering tree

## Note

In the banner plot, observation labels are only printed when the number of observations is limited less than `nmax.lab` (35, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

For the dendrogram, more flexibility than via `pltree()` is provided by `dg <- as.dendrogram(x)` and plotting `dg` via `plot.dendrogram`.

| xax.pretty  | logical or integer indicating if <a href="#">pretty(*, n = xax.pretty)</a> should be used for the x axis. xax.pretty = FALSE is for back compatibility.                                   |
| ...         | graphical parameters (see <a href="#">par</a> ) may also be supplied and are passed to <a href="#">bannerplot()</a> or <a href="#">pltree()</a> , respectively.                           |

## Details

When `ask = TRUE`, rather than producing each plot sequentially, `plot.diana` displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted one must set `par(ask= TRUE)` before invoking the plot command.

The banner displays the hierarchy of clusters, and is equivalent to a tree. See Rousseeuw (1986) or chapter 6 of Kaufman and Rousseeuw (1990). The banner plots the diameter of each cluster being splitted. The observations are listed in the order found by the `diana` algorithm, and the numbers in the `height` vector are represented as bars between the observations.

The leaves of the clustering tree are the original observations. A branch splits up at the diameter of the cluster being splitted.

## Side Effects

An appropriate plot is produced on the current graphics device. This can be one or both of the following choices:

- Banner
- Clustering tree

## Note

In the banner plot, observation labels are only printed when the number of observations is limited less than `nmax.lab` (35, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

## References

```
example(diana) # -> dv <- diana(...)\n\nplot(dv, which = 1, nmax.lab = 100)\n\n## wider labels :\nop <- par(mar = par("mar") + c(0, 2, 0, 0))\nplot(dv, which = 1, nmax.lab = 100, max.strlen = 12)\npar(op)
```

---

plot.mona

*Banner of Monothetic Divisive Hierarchical Clusterings*

---

## Description

Creates the banner of a `mona` object.

**Usage**

```
## S3 method for class 'mona'
plot(x, main = paste("Banner of ", deparse1(x$call)),
      sub = NULL, xlab = "Separation step",
      col = c(2,0), axes = TRUE, adj = 0,
      nmax.lab = 35, max.strlen = 5, ...)
```

**Arguments**

|                         |  |
|-------------------------|--|
| <code>x</code>          | an object of class "mona", typically created by <code>mona(.)</code> .                                       |
| <code>main, sub</code>  | main and sub titles for the plot, with convenient defaults. See documentation in <code>plot.default</code> . |
| <code>xlab</code>       | x axis label, see <code>title</code> .   |
| <code>col, adj</code>   | graphical parameters passed to <code>bannerplot()</code> .   |
| <code>axes</code>       | logical, indicating if (labeled) axes should be drawn.   |
| <code>nmax.lab</code>   | integer indicating the number of labels which is considered too large for labeling.                          |
| <code>max.strlen</code> | positive integer giving the length to which strings are truncated in labeling.                               |
| <code>...</code>        | further graphical arguments are passed to <code>bannerplot()</code> and <code>text</code> .                  |

**Details**

Plots the separation step at which clusters are splitted. The observations are given in the order found by the `mona` algorithm, the numbers in the `step` vector are represented as bars between the observations.

When a long bar is drawn between two observations, those observations have the same value for each variable. See chapter 7 of Kaufman and Rousseeuw (1990).

**Side Effects**

A banner is plotted on the current graphics device.

**Note**

In the banner plot, observation labels are only printed when the number of observations is limited less than `nmax.lab` (35, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

**References**

see those in `plot.agnes`.

**See Also**

`mona`, `mona.object`, `par`.

---

plot.partition      *Plot of a Partition of the Data Set*

---

## Description

Creates plots for visualizing a partition object.

## Usage

```
## S3 method for class 'partition'
plot(x, ask = FALSE, which.plots = NULL,
     nmax.lab = 40, max.strlen = 5, data = x$data, dist = NULL,
     stand = FALSE, lines = 2,
     shade = FALSE, color = FALSE, labels = 0, plotchar = TRUE,
     span = TRUE, xlim = NULL, ylim = NULL, main = NULL, ...)
```

## Arguments

|  |   |
|--|---|
| <code>x</code>   | an object of class "partition", typically created by the functions <a href="#">pam</a> , <a href="#">clara</a> , or <a href="#">fanny</a> .   |
| <code>ask</code>   | logical; if true and <code>which.plots</code> is NULL, <code>plot.partition</code> operates in interactive mode, via <a href="#">menu</a> .   |
| <code>which.plots</code>   | integer vector or NULL (default), the latter producing both plots. Otherwise, <code>which.plots</code> must contain integers of 1 for a <i>clusplot</i> or 2 for <i>silhouette</i> .  |
| <code>nmax.lab</code>  | integer indicating the number of labels which is considered too large for single-name labeling the silhouette plot.   |
| <code>max.strlen</code>  | positive integer giving the length to which strings are truncated in silhouette plot labeling.  |
| <code>data</code>  | numeric matrix with the scaled data; per default taken from the partition object <code>x</code> , but can be specified explicitly.  |
| <code>dist</code>  | when <code>x</code> does not have a <code>diss</code> component as for <a href="#">pam</a> (*, <code>keep.diss=FALSE</code> ), <code>dist</code> must be the dissimilarity if a <i>clusplot</i> is desired.                       |
| <code>stand, lines, shade, color, labels, plotchar, span, xlim, ylim, main, ...</code> | All optional arguments available for the <a href="#">clusplot.default</a> function (except for the <code>diss</code> one) and graphical parameters (see <a href="#">par</a> ) may also be supplied as arguments to this function. |

## Details

When `ask=TRUE`, rather than producing each plot sequentially, `plot.partition` displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted, call `par(ask=TRUE)` before invoking the plot command.

The *clusplot* of a cluster partition consists of a two-dimensional representation of the observations, in which the clusters are indicated by ellipses (see [clusplot.partition](#) for more details).

The *silhouette plot* of a nonhierarchical clustering is fully described in Rousseeuw (1987) and in chapter 2 of Kaufman and Rousseeuw (1990). For each observation *i*, a bar is drawn, representing its silhouette width *s(i)*, see [silhouette](#) for details. Observations are grouped per cluster, starting

with cluster 1 at the top. Observations with a large  $s(i)$  (almost 1) are very well clustered, a small  $s(i)$  (around 0) means that the observation lies between two clusters, and observations with a negative  $s(i)$  are probably placed in the wrong cluster.

A clustering can be performed for several values of  $k$  (the number of clusters). Finally, choose the value of  $k$  with the largest overall average silhouette width.

### Side Effects

An appropriate plot is produced on the current graphics device. This can be one or both of the following choices:

Clusplot

Silhouette plot

### Note

In the silhouette plot, observation labels are only printed when the number of observations is less than `nmax.lab` (40, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

For more flexibility, use `plot(silhouette(x), ...)`, see [plot.silhouette](#).

Further, the references in [plot.agnes](#).

### See Also

[partition.object](#), [clusplot.partition](#), [clusplot.default](#), [pam](#),  
[pam.object](#), [clara](#), [clara.object](#), [fanny](#), [fanny.object](#), [par](#).

### Examples

```
## generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),
           cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
plot(pam(x, 2))

## Save space not keeping data in clus.object, and still clusplot() it:
data(xclara)
cx <- clara(xclara, 3, keep.data = FALSE)
cx$data # is NULL
plot(cx, data = xclara)
```

### Description

`pltree()` Draws a clustering tree (“dendrogram”) on the current graphics device. We provide the `twins` method draws the tree of a `twins` object, i.e., hierarchical clustering, typically resulting from [agnes\(\)](#) or [diana\(\)](#).

## Usage

```
pltree(x, ...)
## S3 method for class 'twins'
pltree(x, main = paste("Dendrogram of ", deparse1(x$call)),
      labels = NULL, ylab = "Height", ...)
```

## Arguments

|                     |   |
|---------------------|---|
| <code>x</code>      | in general, an R object for which a <code>pltree</code> method is defined; specifically, an object of class "twins", typically created by either <code>agnes()</code> or <code>diana()</code> . |
| <code>main</code>   | main title with a sensible default.   |
| <code>labels</code> | labels to use; the default is constructed from <code>x</code> .   |
| <code>ylab</code>   | label for y-axis.   |
| <code>...</code>    | graphical parameters (see <code>par</code> ) may also be supplied as arguments to this function.  |

## Details

Creates a plot of a clustering tree given a `twins` object. The leaves of the tree are the original observations. In case of an agglomerative clustering, two branches come together at the distance between the two clusters being merged. For a divisive clustering, a branch splits up at the diameter of the cluster being splitted.

Note that currently the method function simply calls `plot(as.hclust(x), ...)`, which dispatches to `plot.hclust(...)`. If more flexible plots are needed, consider `xx <- as.dendrogram(as.hclust(x))` and plotting `xx`, see `plot.dendrogram`.

## Value

a NULL value is returned.

## See Also

`agnes`, `agnes.object`, `diana`, `diana.object`, `hclust`, `par`, `plot.agnes`, `plot.diana`.

## Examples

```
data(votes.repub)
agn <- agnes(votes.repub)
pltree(agn)

dagn <- as.dendrogram(as.hclust(agn))
dagn2 <- as.dendrogram(as.hclust(agn), hang = 0.2)
op <- par(mar = par("mar") + c(0,0,0, 2)) # more space to the right
plot(dagn2, horiz = TRUE)
plot(dagn, horiz = TRUE, center = TRUE,
     nodePar = list(lab.cex = 0.6, lab.col = "forest green", pch = NA),
     main = deparse(agn$call))
par(op)
```

---

 pluton

---

*Isotopic Composition Plutonium Batches*

---

## Description

The `pluton` data frame has 45 rows and 4 columns, containing percentages of isotopic composition of 45 Plutonium batches.

## Usage

```
data(pluton)
```

## Format

This data frame contains the following columns:

**Pu238** the percentages of  $^{238}\text{Pu}$ , always less than 2 percent.

**Pu239** the percentages of  $^{239}\text{Pu}$ , typically between 60 and 80 percent (from neutron capture of Uranium,  $^{238}\text{U}$ ).

**Pu240** percentage of the plutonium 240 isotope.

**Pu241** percentage of the plutonium 241 isotope.

## Details

Note that the percentage of plutonium~242 can be computed from the other four percentages, see the examples.

In the reference below it is explained why it is very desirable to combine these plutonium patches in three groups of similar size.

## Source

Available as ‘`pluton.dat`’ from the archive of the University of Antwerpen, ‘`.../datasets/clusplot-examples.tar.gz`’, no longer available.

## References

Rousseeuw, P.J. and Kaufman, L and Trauwaert, E. (1996) Fuzzy clustering using scatter matrices, *Computational Statistics and Data Analysis* **23**(1), 135–151.

## Examples

```
data(pluton)

hist(apply(pluton,1,sum), col = "gray") # between 94% and 100%
pu5 <- pluton
pu5$Pu242 <- 100 - apply(pluton,1,sum) # the remaining isotope.
pairs(pu5)
```

---

predict.ellipsoid *Predict Method for Ellipsoid Objects*

---

## Description

Compute points on the ellipsoid boundary, mostly for drawing.

## Usage

```
predict.ellipsoid(object, n.out=201, ...)
## S3 method for class 'ellipsoid'
predict(object, n.out=201, ...)
ellipsoidPoints(A, d2, loc, n.half = 201)
```

## Arguments

|               |   |
|---------------|---|
| object        | an object of class <code>ellipsoid</code> , typically from <code>ellipsoidhull()</code> ; alternatively any list-like object with proper components, see details below. |
| n.out, n.half | half the number of points to create.  |
| A, d2, loc    | arguments of the auxiliary <code>ellipsoidPoints</code> , see below.  |
| ...           | passed to and from methods.   |

## Details

Note `ellipsoidPoints` is the workhorse function of `predict.ellipsoid` a standalone function and method for `ellipsoid` objects, see [ellipsoidhull](#). The class of object is not checked; it must solely have valid components `loc` (length  $p$ ), the  $p \times p$  matrix `cov` (corresponding to `A`) and `d2` for the center, the shape (“covariance”) matrix and the squared average radius (or distance) or `qchisq(*, p)` quantile.

Unfortunately, this is only implemented for  $p = 2$ , currently; contributions for  $p \geq 3$  are *very welcome*.

## Value

a numeric matrix of dimension  $2 \times n.out$  times  $p$ .

## See Also

[ellipsoidhull](#), [volume.ellipsoid](#).

## Examples

```
## see also example(ellipsoidhull)

## Robust vs. L.S. covariance matrix
set.seed(143)
x <- rt(200, df=3)
y <- 3*x + rt(200, df=2)
plot(x, y, main="non-normal data (N=200)")
mtext("with classical and robust cov.matrix ellipsoids")
X <- cbind(x, y)
```

```

C.ls <- cov(X) ; m.ls <- colMeans(X)
d2.99 <- qchisq(0.99, df = 2)
lines(ellipsoidPoints(C.ls, d2.99, loc=m.ls), col="green")
if(require(MASS)) {
  Cxy <- cov.rob(cbind(x,y))
  lines(ellipsoidPoints(Cxy$cov, d2 = d2.99, loc=Cxy$center), col="red")
}# MASS

```

---

print.agnes

---

*Print Method for AGNES Objects*

---

### Description

Prints the call, agglomerative coefficient, ordering of objects and distances between merging clusters ('Height') of an `agnes` object.

This is a method for the generic `print()` function for objects inheriting from class `agnes`, see `agnes.object`.

### Usage

```

## S3 method for class 'agnes'
print(x, ...)

```

### Arguments

`x` an `agnes` object.  
`...` potential further arguments (required by generic).

### See Also

`summary.agnes` producing more output; `agnes`, `agnes.object`, `print`, `print.default`.

---

print.clara

---

*Print Method for CLARA Objects*

---

### Description

Prints the best sample, medoids, clustering vector and objective function of `clara` object.

This is a method for the function `print()` for objects inheriting from class `clara`.

### Usage

```

## S3 method for class 'clara'
print(x, ...)

```

### Arguments

`x` a `clara` object.  
`...` potential further arguments (require by generic).

**See Also**

`summary.clara` producing more output; `clara`, `clara.object`, `print`, `print.default`.

---

`print.diana`

*Print Method for DIANA Objects*

---

**Description**

Prints the ordering of objects, diameters of splitted clusters, and divisive coefficient of a `diana` object.

This is a method for the function `print()` for objects inheriting from class `diana`.

**Usage**

```
## S3 method for class 'diana'
print(x, ...)
```

**Arguments**

`x` a `diana` object.

`...` potential further arguments (require by generic).

**See Also**

`diana`, `diana.object`, `print`, `print.default`.

---

`print.dissimilarity`

*Print and Summary Methods for Dissimilarity Objects*

---

**Description**

Print or summarize the distances and the attributes of a `dissimilarity` object.

These are methods for the functions `print()` and `summary()` for `dissimilarity` objects. See `print`, `print.default`, or `summary` for the general behavior of these.

**Usage**

```
## S3 method for class 'dissimilarity'
print(x, diag = NULL, upper = NULL,
      digits = getOption("digits"), justify = "none", right = TRUE, ...)
## S3 method for class 'dissimilarity'
summary(object,
         digits = max(3, getOption("digits") - 2), ...)
## S3 method for class 'summary.dissimilarity'
print(x, ...)
```

**Arguments**

`x, object` a dissimilarity object or a `summary.dissimilarity` one for `print.summary.dissimilarity()`.

`digits` the number of digits to use, see `print.default`.

`diag, upper, justify, right` optional arguments specifying how the triangular dissimilarity matrix is printed; see `print.dist`.

`...` potential further arguments (require by generic).

**See Also**

`daisy`, `dissimilarity.object`, `print`, `print.default`, `print.dist`.

**Examples**

```
## See example(daisy)

sd <- summary(daisy(matrix(rnorm(100), 20, 5)))
sd # -> print.summary.dissimilarity(.)
str(sd)
```

---

`print.fanny`

*Print and Summary Methods for FANNY Objects*

---

**Description**

Prints the objective function, membership coefficients and clustering vector of `fanny` object.

This is a method for the function `print()` for objects inheriting from class `fanny`.

**Usage**

```
## S3 method for class 'fanny'
print(x, digits = getOption("digits"), ...)
## S3 method for class 'fanny'
summary(object, ...)
## S3 method for class 'summary.fanny'
print(x, digits = getOption("digits"), ...)
```

**Arguments**

`x, object` a `fanny` object.

`digits` number of significant digits for printing, see `print.default`.

`...` potential further arguments (required by generic).

**See Also**

`fanny`, `fanny.object`, `print`, `print.default`.

---

`print.mona`*Print Method for MONA Objects*

---

**Description**

Prints the ordering of objects, separation steps, and used variables of a `mona` object.

This is a method for the function `print()` for objects inheriting from class `mona`.

**Usage**

```
## S3 method for class 'mona'
print(x, ...)
```

**Arguments**

|                  |   |
|------------------|---|
| <code>x</code>   | a <code>mona</code> object.                       |
| <code>...</code> | potential further arguments (require by generic). |

**See Also**

`mona`, `mona.object`, `print`, `print.default`.

---

`print.pam`*Print Method for PAM Objects*

---

**Description**

Prints the medoids, clustering vector and objective function of `pam` object.

This is a method for the function `print()` for objects inheriting from class `pam`.

**Usage**

```
## S3 method for class 'pam'
print(x, ...)
```

**Arguments**

|                  |   |
|------------------|---|
| <code>x</code>   | a <code>pam</code> object.                        |
| <code>...</code> | potential further arguments (require by generic). |

**See Also**

`pam`, `pam.object`, `print`, `print.default`.

---

 ruspini

*Ruspini Data*

---

### Description

The Ruspini data set, consisting of 75 points in four groups that is popular for illustrating clustering techniques.

### Usage

```
data(ruspini)
```

### Format

A data frame with 75 observations on 2 variables giving the x and y coordinates of the points, respectively.

### Source

E. H. Ruspini (1970) Numerical methods for fuzzy clustering. *Inform. Sci.* **2**, 319–350.

### References

see those in [agnes](#).

### Examples

```
data(ruspini)

## Plot similar to Figure 4 in Stryuf et al (1996)
## Not run: plot(pam(ruspini, 4), ask = TRUE)

## Plot similar to Figure 6 in Stryuf et al (1996)
plot(fanny(ruspini, 5))
```

---

 silhouette

*Compute or Extract Silhouette Information from Clustering*

---

### Description

Compute silhouette information according to a given clustering in  $k$  clusters.

## Usage

```

silhouette(x, ...)
## Default S3 method:
  silhouette(x, dist, dmatrix, ...)
## S3 method for class 'partition'
silhouette(x, ...)
## S3 method for class 'clara'
silhouette(x, full = FALSE, subset = NULL, ...)

sortSilhouette(object, ...)
## S3 method for class 'silhouette'
summary(object, FUN = mean, ...)
## S3 method for class 'silhouette'
plot(x, nmax.lab = 40, max.strlen = 5,
     main = NULL, sub = NULL, xlab = expression("Silhouette width " * s[i]),
     col = "gray", do.col.sort = length(col) > 1, border = 0,
     cex.names = par("cex.axis"), do.n.k = TRUE, do.clus.stat = TRUE, ...)

```

## Arguments

|                                     |  |
|-------------------------------------|--|
| <code>x</code>                      | an object of appropriate class; for the default method an integer vector with $k$ different integer cluster codes or a list with such an <code>x\$clustering</code> component. Note that silhouette statistics are only defined if $2 \leq k \leq n - 1$ .   |
| <code>dist</code>                   | a dissimilarity object inheriting from class <code>dist</code> or coercible to one. If not specified, <code>dmatrix</code> must be.  |
| <code>dmatrix</code>                | a symmetric dissimilarity matrix ( $n \times n$ ), specified instead of <code>dist</code> , which can be more efficient.   |
| <code>full</code>                   | logical or number in $[0, 1]$ specifying if a <i>full</i> silhouette should be computed for <code>clara</code> object. When a number, say $f$ , for a random <code>sample.int(n, size = f*n)</code> of the data the silhouette values are computed. This requires $O((f*n)^2)$ memory, since the full dissimilarity of the (sub)sample (see <code>daisy</code> ) is needed internally. |
| <code>subset</code>                 | a subset from $1:n$ , specified instead of <code>full</code> to specify the indices of the observations to be used for the silhouette computations.  |
| <code>object</code>                 | an object of class <code>silhouette</code> .   |
| <code>...</code>                    | further arguments passed to and from methods.  |
| <code>FUN</code>                    | function used to summarize silhouette widths.  |
| <code>nmax.lab</code>               | integer indicating the number of labels which is considered too large for single-name labeling the silhouette plot.  |
| <code>max.strlen</code>             | positive integer giving the length to which strings are truncated in silhouette plot labeling.   |
| <code>main, sub, xlab</code>        | arguments to <code>title</code> ; have a sensible non-NULL default here.   |
| <code>col, border, cex.names</code> | arguments passed <code>barplot()</code> ; note that the default used to be <code>col = heat.colors(n)</code> , <code>border = par("fg")</code> instead.<br><code>col</code> can also be a color vector of length $k$ for clusterwise coloring, see also <code>do.col.sort</code> :   |

`do.col.sort` logical indicating if the colors `col` should be sorted “along” the silhouette; this is useful for casewise or clusterwise coloring.

`do.n.k` logical indicating if  $n$  and  $k$  “title text” should be written.

`do.clus.stat` logical indicating if cluster size and averages should be written right to the silhouettes.

## Details

For each observation  $i$ , the *silhouette width*  $s(i)$  is defined as follows:

Put  $a(i)$  = average dissimilarity between  $i$  and all other points of the cluster to which  $i$  belongs (if  $i$  is the *only* observation in its cluster,  $s(i) := 0$  without further calculations). For all *other* clusters  $C$ , put  $d(i, C)$  = average dissimilarity of  $i$  to all observations of  $C$ . The smallest of these  $d(i, C)$  is  $b(i) := \min_C d(i, C)$ , and can be seen as the dissimilarity between  $i$  and its “neighbor” cluster, i.e., the nearest one to which it does *not* belong. Finally,

$$s(i) := \frac{b(i) - a(i)}{\max(a(i), b(i))}.$$

`silhouette.default()` is now based on C code donated by Romain Francois (the R version being still available as `cluster::silhouetteR`).

Observations with a large  $s(i)$  (almost 1) are very well clustered, a small  $s(i)$  (around 0) means that the observation lies between two clusters, and observations with a negative  $s(i)$  are probably placed in the wrong cluster.

## Value

`silhouette()` returns an object, `sil`, of class `silhouette` which is an  $n \times 3$  matrix with attributes. For each observation  $i$ , `sil[i, ]` contains the cluster to which  $i$  belongs as well as the neighbor cluster of  $i$  (the cluster, not containing  $i$ , for which the average dissimilarity between its observations and  $i$  is minimal), and the silhouette width  $s(i)$  of the observation. The `colnames` correspondingly are `c("cluster", "neighbor", "sil_width")`.

`summary(sil)` returns an object of class `summary.silhouette`, a list with components

`si.summary`: numerical `summary` of the individual silhouette widths  $s(i)$ .

`clus.avg.widths`: numeric (rank 1) array of clusterwise *means* of silhouette widths where `mean = FUN` is used.

`avg.width`: the total mean `FUN(s)` where  $s$  are the individual silhouette widths.

`clus.sizes`: `table` of the  $k$  cluster sizes.

`call`: if available, the `call` creating `sil`.

`Ordered`: logical identical to `attr(sil, "Ordered")`, see below.

`sortSilhouette(sil)` orders the rows of `sil` as in the silhouette plot, by cluster (increasingly) and decreasing silhouette width  $s(i)$ .

`attr(sil, "Ordered")` is a logical indicating if `sil` is ordered as by `sortSilhouette()`.

In that case, `rownames(sil)` will contain case labels or numbers, and

`attr(sil, "iOrd")` the ordering index vector.

**Note**

While `silhouette()` is *intrinsic* to the `partition` clusterings, and hence has a (trivial) method for these, it is straightforward to get silhouettes from hierarchical clusterings from `silhouette.default()` with `cutree()` and distance as input.

By default, for `clara()` partitions, the silhouette is just for the best random *subset* used. Use `full = TRUE` to compute (and later possibly plot) the full silhouette.

**Examples**

```
data(ruspini)
pr4 <- pam(ruspini, 4)
str(si <- silhouette(pr4))
(ssi <- summary(si))
plot(si) # silhouette plot
plot(si, col = c("red", "green", "blue", "purple")) # with cluster-wise coloring

si2 <- silhouette(pr4$clustering, dist(ruspini, "canberra"))
summary(si2) # has small values: "canberra"'s fault
plot(si2, nmax= 80, cex.names=0.6)

op <- par(mfrow= c(3,2), oma= c(0,0, 3, 0),
          mgp= c(1.6, .8, 0), mar= .1+c(4,2,2,2))
for(k in 2:6)
  plot(silhouette(pam(ruspini, k=k)), main = paste("k = ", k), do.n.k=FALSE)
mtext("PAM(Ruspini) as in Kaufman & Rousseeuw, p.101",
      outer = TRUE, font = par("font.main"), cex = par("cex.main")); frame()

## the same with cluster-wise colours:
c6 <- c("tomato", "forest green", "dark blue", "purple2", "goldenrod4", "gray20")
for(k in 2:6)
  plot(silhouette(pam(ruspini, k=k)), main = paste("k = ", k), do.n.k=FALSE,
       col = c6[1:k])
par(op)

## clara(): standard silhouette is just for the best random subset
data(xclara)
set.seed(7)
str(xclk <- xclara[ sample(nrow(xclara), size = 1000) ,]) # rownames == indices
cl3 <- clara(xclk, 3)
plot(silhouette(cl3)) # only of the "best" subset of 46
## The full silhouette: internally needs large (36 MB) dist object:
sf <- silhouette(cl3, full = TRUE) ## this is the same as
s.full <- silhouette(cl3$clustering, daisy(xclk))
stopifnot(all.equal(sf, s.full, check.attributes = FALSE, tolerance = 0))
## color dependent on original "3 groups of each 1000": % __FIXME ??__
```

```

plot(sf, col = 2+ as.integer(names(cl3$clustering) ) %% 1000,
     main ="plot(silhouette(clara(.), full = TRUE))")

## Silhouette for a hierarchical clustering:
ar <- agnes(ruspini)
si3 <- silhouette(cutree(ar, k = 5), # k = 4 gave the same as pam() above
                 daisy(ruspini))
stopifnot(is.data.frame(di3 <- as.data.frame(si3)))
plot(si3, nmax = 80, cex.names = 0.5)
## 2 groups: Agnes() wasn't too good:
si4 <- silhouette(cutree(ar, k = 2), daisy(ruspini))
plot(si4, nmax = 80, cex.names = 0.5)

```

sizeDiss

*Sample Size of Dissimilarity Like Object***Description**

Returns the number of observations (*sample size*) corresponding to a dissimilarity like object, or equivalently, the number of rows or columns of a matrix when only the lower or upper triangular part (without diagonal) is given.

It is nothing else but the inverse function of  $f(n) = n(n-1)/2$ .

**Usage**

```
sizeDiss(d)
```

**Arguments**

**d** any R object with length (typically)  $n(n-1)/2$ .

**Value**

a number;  $n$  if `length(d) == n(n-1)/2`, NA otherwise.

**See Also**

`dissimilarity.object` and also `as.dist` for class dissimilarity and dist objects which have a `Size` attribute.

**Examples**

```

sizeDiss(1:10) # 5, since 10 == 5 * (5 - 1) / 2
sizeDiss(1:9) # NA

n <- 1:100
stopifnot(n == sapply( n*(n-1)/2, function(n) sizeDiss(logical(n))))

```

---

summary.agnes*Summary Method for 'agnes' Objects*

---

**Description**

Returns (and prints) a summary list for an `agnes` object. Printing gives more output than the corresponding `print.agnes` method.

**Usage**

```
## S3 method for class 'agnes'
summary(object, ...)
## S3 method for class 'summary.agnes'
print(x, ...)
```

**Arguments**

`x, object`      a `agnes` object.  
`...`            potential further arguments (require by generic).

**See Also**

`agnes`, `agnes.object`.

**Examples**

```
data(agriculture)
summary(agnes(agriculture))
```

---

summary.clara*Summary Method for 'clara' Objects*

---

**Description**

Returns (and prints) a summary list for a `clara` object. Printing gives more output than the corresponding `print.clara` method.

**Usage**

```
## S3 method for class 'clara'
summary(object, ...)
## S3 method for class 'summary.clara'
print(x, ...)
```

**Arguments**

`x, object`      a `clara` object.  
`...`            potential further arguments (require by generic).

**See Also**

[clara.object](#)

**Examples**

```
## generate 2000 objects, divided into 5 clusters.
set.seed(47)
x <- rbind(cbind(rnorm(400, 0, 4), rnorm(400, 0, 4)),
           cbind(rnorm(400, 10, 8), rnorm(400, 40, 6)),
           cbind(rnorm(400, 30, 4), rnorm(400, 0, 4)),
           cbind(rnorm(400, 40, 4), rnorm(400, 20, 2)),
           cbind(rnorm(400, 50, 4), rnorm(400, 50, 4))
)
clx5 <- clara(x, 5)
## Misclassification table:
table(rep(1:5, rep(400, 5)), clx5$clust) # -> 1 "error"
summary(clx5)

## Graphically:
par(mfrow = c(3, 1), mgp = c(1.5, 0.6, 0), mar = par("mar") - c(0, 0, 2, 0))
plot(x, col = rep(2:6, rep(400, 5)))
plot(clx5)
```

---

summary.diana

*Summary Method for 'diana' Objects*

---

**Description**

Returns (and prints) a summary list for a diana object.

**Usage**

```
## S3 method for class 'diana'
summary(object, ...)
## S3 method for class 'summary.diana'
print(x, ...)
```

**Arguments**

x, object      a [diana](#) object.

...            potential further arguments (require by generic).

**See Also**

[diana](#), [diana.object](#).

---

summary.mona*Summary Method for 'mona' Objects*

---

**Description**

Returns (and prints) a summary list for a mona object.

**Usage**

```
## S3 method for class 'mona'
summary(object, ...)
## S3 method for class 'summary.mona'
print(x, ...)
```

**Arguments**

x, object      a [mona](#) object.  
...            potential further arguments (require by generic).

**See Also**

[mona](#), [mona.object](#).

---

summary.pam*Summary Method for PAM Objects*

---

**Description**

Summarize a [pam](#) object and return an object of class `summary.pam`. There's a [print](#) method for the latter.

**Usage**

```
## S3 method for class 'pam'
summary(object, ...)
## S3 method for class 'summary.pam'
print(x, ...)
```

**Arguments**

x, object      a [pam](#) object.  
...            potential further arguments (require by generic).

**See Also**

[pam](#), [pam.object](#).

---

|              |                                       |
|--------------|---------------------------------------|
| twins.object | <i>Hierarchical Clustering Object</i> |
|--------------|---------------------------------------|

---

### Description

The objects of class "twins" represent an agglomerative or divisive (polythetic) hierarchical clustering of a dataset.

### Value

See [agnes.object](#) and [diana.object](#) for details.

### GENERATION

This class of objects is returned from `agnes` or `diana`.

### METHODS

The "twins" class has a method for the following generic function: `pltree`.

### INHERITANCE

The following classes inherit from class "twins": "agnes" and "diana".

### See Also

[agnes,diana](#).

---

|                  |   |
|------------------|---|
| volume.ellipsoid | <i>Compute the Volume (of an Ellipsoid)</i> |
|------------------|---|

---

### Description

Compute the volume of geometric R object. This is a generic function and has a method for `ellipsoid` objects (typically resulting from [ellipsoidhull\(\)](#)).

### Usage

```
volume(object, ...)
## S3 method for class 'ellipsoid'
volume(object, log = FALSE, ...)
```

### Arguments

|        |   |
|--------|---|
| object | an R object the volume of which is wanted; for the <code>ellipsoid</code> method, an object of that class (see <a href="#">ellipsoidhull</a> or the example below). |
| log    | <a href="#">logical</a> indicating if the volume should be returned in log scale. Maybe needed in largish dimensions.   |
| ...    | potential further arguments of methods, e.g. <code>log</code> .   |

**Value**

a number, the volume  $V$  (or  $\log(V)$  if `log = TRUE`) of the given object.

**Author(s)**

Martin Maechler (2002, extracting from former `clusplot` code); Keefe Murphy (2019) provided code for dimensions  $d > 2$ .

**See Also**

`ellipsoidhull` for spanning ellipsoid computation.

**Examples**

```
## example(ellipsoidhull) # which defines 'ellipsoid' object <namefoo>

myEl <- structure(list(cov = rbind(c(3,1),1:2), loc = c(0,0), d2 = 10),
                    class = "ellipsoid")
volume(myEl) # i.e. "area" here (d = 2)
myEl # also mentions the "volume"

set.seed(1)
d5 <- matrix(rt(500, df=3), 100, 5)
e5 <- ellipsoidhull(d5)
```

---

votes.repub

*Votes for Republican Candidate in Presidential Elections*

---

**Description**

A data frame with the percents of votes given to the republican candidate in presidential elections from 1856 to 1976. Rows represent the 50 states, and columns the 31 elections.

**Usage**

```
data(votes.repub)
```

**Source**

S. Peterson (1973): *A Statistical History of the American Presidential Elections*. New York: Frederick Ungar Publishing Co.

Data from 1964 to 1976 is from R. M. Scammon, *American Votes 12*, Congressional Quarterly.

xclara

*Bivariate Data Set with 3 Clusters***Description**

An artificial data set consisting of 3000 points in 3 quite well-separated clusters.

**Usage**

```
data(xclara)
```

**Format**

A data frame with 3000 observations on 2 numeric variables (named V1 and V2) giving the  $x$  and  $y$  coordinates of the points, respectively.

**Note**

Our version of the `xclara` is slightly more rounded than the one from `read.table("xclara.dat")` and the relative difference measured by `all.equal` is  $1.15\text{e-}7$  for V1 and  $1.17\text{e-}7$  for V2 which suggests that our version has been the result of a `options(digits = 7)` formatting.

Previously (before May 2017), it was claimed the three cluster were each of size 1000, which is clearly wrong. `pam(*, 3)` gives cluster sizes of 899, 1149, and 952, which apart from seven “outliers” (or “mislabellings”) correspond to observation indices  $\{1 : 900\}$ ,  $\{901 : 2050\}$ , and  $\{2051 : 3000\}$ , see the example.

**Source**

Sample data set accompanying the reference below (file ‘`xclara.dat`’ in side ‘`clus_examples.tar.gz`’).

**References**

Anja Struyf, Mia Hubert & Peter J. Rousseeuw (1996) Clustering in an Object-Oriented Environment. *Journal of Statistical Software* **1**. doi:10.18637/jss.v001.i04

**Examples**

```
## Visualization: Assuming groups are defined as {1:1000}, {1001:2000}, {2001:3000}
plot(xclara, cex = 3/4, col = rep(1:3, each=1000))
p.ID <- c(78, 1411, 2535) ## PAM's medoid indices == pam(xclara, 3)$id.med
text(xclara[p.ID,], labels = 1:3, cex=2, col=1:3)

px <- pam(xclara, 3) ## takes ~2 seconds
cxcl <- px$clustering ; iCl <- split(seq_along(cxcl), cxcl)
boxplot(iCl, range = 0.7, horizontal=TRUE,
        main = "Indices of the 3 clusters of pam(xclara, 3)")

## Look more closely now:
bxCl <- boxplot(iCl, range = 0.7, plot=FALSE)
## We see 3 + 2 + 2 = 7 clear "outlier"s or "wrong group" observations:
with(bxCl, rbind(out, group))
```

```
## out    1038 1451 1610    30  327  562  770
## group   1     1     1     2     2     3     3
## Apart from these, what are the robust ranges of indices? -- Robust range:
t(iR <- bxCl$stats[c(1,5),])
##      1   900
##    901 2050
##   2051 3000
gc <- adjustcolor("gray20",1/2)
abline(v = iR, col = gc, lty=3)
axis(3, at = c(0, iR[2,]), padj = 1.2, col=gc, col.axis=gc)
```

## Chapter 21

# The codetools package

---

checkUsage

*Check R Code for Possible Problems*

---

### Description

Check R code for possible problems.

### Usage

```
checkUsage(fun, name = "<anonymous>", report = cat, all = FALSE,
            suppressLocal = FALSE, suppressParamAssigns = !all,
            suppressParamUnused = !all, suppressFundefMismatch = FALSE,
            suppressLocalUnused = FALSE, suppressNoLocalFun = !all,
            skipWith = FALSE, suppressUndefined = dfltSuppressUndefined,
            suppressPartialMatchArgs = TRUE)
checkUsageEnv(env, ...)
checkUsagePackage(pack, ...)
```

### Arguments

|                      |   |
|----------------------|---|
| fun                  | closure.  |
| name                 | character; name of closure.                               |
| env                  | environment containing closures to check.                 |
| pack                 | character naming package to check.                        |
| ...                  | options to be passed to checkUsage.                       |
| report               | function to use to report possible problems.              |
| all                  | logical; report all possible problems if TRUE.            |
| suppressLocal        | suppress all local variable warnings.                     |
| suppressParamAssigns | suppress warnings about assignments to formal parameters. |
| suppressParamUnused  | suppress warnings about unused formal parameters.         |

```

suppressFundefMismatch
    suppress warnings about multiple local function definitions with different formal
    argument lists
suppressLocalUnused
    suppress warnings about unused local variables
suppressNoLocalFun
    suppress warnings about using local variables as functions with no apparent
    local function definition
skipWith      logical; if true, do not examine code portion of with or within expressions.
suppressUndefined
    suppress warnings about undefined global functions and variables.
suppressPartialMatchArgs
    suppress warnings about partial argument matching

```

### Details

`checkUsage` checks a single R closure. Options control which possible problems to report. The default settings are moderately verbose. A first pass might use `suppressLocal=TRUE` to suppress all information related to local variable usage. The `suppressXYZ` values can either be scalar logicals or character vectors; then they are character vectors they only suppress problem reports for the variables with names in the vector.

`checkUsageEnv` and `checkUsagePackage` are convenience functions that apply `checkUsage` to all closures in an environment or a package. `checkUsagePackage` requires that the package be loaded. If the package has a name space then the internal name space frame is checked.

### Author(s)

Luke Tierney

### Examples

```

checkUsage(checkUsage)
checkUsagePackage("codetools", all=TRUE)
## Not run: checkUsagePackage("base", suppressLocal=TRUE)

```

---

codetools

*Low Level Code Analysis Tools for R*

---

### Description

These functions provide some tools for analysing R code. Mainly intended to support the other tools in this package and byte code compilation.

### Usage

```

collectLocals(e, collect)
collectUsage(fun, name = "<anonymous>", ...)
constantFold(e, env = NULL, fail = NULL)
findFuncLocals(formals, body)
findLocals(e, envir = .BaseEnv)

```

```

findLocalsList(elist, envir = .BaseEnv)
flattenAssignment(e)
getAssignedVar(e)
isConstantValue(v, w)
makeCodeWalker(..., handler, call, leaf)
makeConstantFolder(..., leaf, handler, call, exit, isLocal, foldable,
                    isConstant, signal)
makeLocalsCollector(..., leaf, handler, isLocal, exit, collect)
makeUsageCollector(fun, ..., name, enterLocal, enterGlobal, enterInternal,
                    startCollectLocals, finishCollectLocals, warn,
                    signal)
walkCode(e, w = makeCodeWalker())

```

### Arguments

|                     |                                 |
|---------------------|---------------------------------|
| e                   | R expression.                   |
| elist               | list of R expressions.          |
| v                   | R object.                       |
| fun                 | closure.                        |
| formals             | formal arguments of a closure.  |
| body                | body of a closure.              |
| name                | character.                      |
| env                 | character.                      |
| envir               | environment.                    |
| w                   | code walker.                    |
| ...                 | extra elements for code walker. |
| collect             | function.                       |
| fail                | function.                       |
| handler             | function.                       |
| call                | function.                       |
| leaf                | function.                       |
| isLocal             | function.                       |
| exit                | function.                       |
| enterLocal          | function.                       |
| enterGlobal         | function.                       |
| enterInternal       | function.                       |
| startCollectLocals  | function.                       |
| finishCollectLocals | function.                       |
| warn                | function.                       |
| signal              | function.                       |
| isConstant          | function.                       |
| foldable            | function.                       |

Luke Tierney

---

`findGlobals`*Find Global Functions and Variables Used by a Closure*

---

**Description**

Finds global functions and variables used by a closure.

**Usage**

```
findGlobals(fun, merge = TRUE)
```

**Arguments**

|                    |                                     |
|--------------------|-------------------------------------|
| <code>fun</code>   | function object; usually a closure. |
| <code>merge</code> | logical                             |

**Details**

The result is an approximation. R semantics only allow variables that might be local to be identified (and event that assumes no use of `assign` and `rm`).

**Value**

Character vector if `merge` is true; otherwise, a list with `functions` and `variables` character vector components. Character vectors are of length zero For non-closures.

**Author(s)**

Luke Tierney

**Examples**

```
findGlobals(findGlobals)
findGlobals(findGlobals, merge = FALSE)
```

---

`showTree`*Print Lisp-Style Representation of R Expression*

---

**Description**

Prints a Lisp-style representation of R expression. This can be useful for understanding how some things are parsed.

**Usage**

```
showTree(e, write = cat)
```

**Arguments**

|                    |   |
|--------------------|---|
| <code>e</code>     | R expression.                                 |
| <code>write</code> | function of one argument to write the result. |

**Author(s)**

Luke Tierney

**Examples**

```
showTree(quote(-3))  
showTree(quote("x"<-1))  
showTree(quote("f"(x)))
```

## Chapter 22

# The foreign package

---

`lookup.xport`

*Lookup Information on a SAS XPORT Format Library*

---

### Description

Scans a file as a SAS XPORT format library and returns a list containing information about the SAS library.

### Usage

```
lookup.xport (file)
```

### Arguments

|                   |   |
|-------------------|---|
| <code>file</code> | character variable with the name of the file to read. The file must be in SAS XPORT format. |
|-------------------|---|

### Value

A list with one component for each dataset in the XPORT format library.

### Author(s)

Saikat DebRoy

### References

SAS Technical Support document TS-140: “The Record Layout of a Data Set in SAS Transport (XPORT) Format” available as <https://support.sas.com/content/dam/SAS/support/en/technical-papers/record-layout-of-a-sas-version-5-or-6-data-set-in-sas-transport-xport-format.pdf>

**Examples**

```
## Not run: ## no XPORT file is installed.
lookup.xport("test.xpt")

## End(Not run)
```

---

read.arff

*Read Data from ARFF Files*

---

**Description**

Reads data from Weka Attribute-Relation File Format (ARFF) files.

**Usage**

```
read.arff(file)
```

**Arguments**

`file` a character string with the name of the ARFF file to read from, or a [connection](#) which will be opened if necessary, and if so closed at the end of the function call.

**Value**

A data frame containing the data from the ARFF file.

**References**

Attribute-Relation File Format [https://waikato.github.io/weka-wiki/formats\\_and\\_processing/arff/](https://waikato.github.io/weka-wiki/formats_and_processing/arff/).

**See Also**

[write.arff](#); functions `write.arff` and `read.arff` in package **RWeka** which provide some support for logicals via conversion to or from factors.

---

read.dbf

*Read a DBF File*

---

**Description**

The function reads a DBF file into a data frame, converting character fields to factors, and trying to respect NULL fields.

The DBF format is documented but not much adhered to. There is no guarantee this will read all DBF files.

**Usage**

```
read.dbf(file, as.is = FALSE)
```

## Arguments

|                    |   |
|--------------------|---|
| <code>file</code>  | name of input file                                    |
| <code>as.is</code> | should character vectors not be converted to factors? |

## Details

DBF is the extension used for files written for the 'XBASE' family of database languages, 'covering the dBase, Clipper, FoxPro, and their Windows equivalents Visual dBase, Visual Objects, and Visual FoxPro, plus some older products' (<https://www.clicketyclick.dk/databases/xbase/format/>). Most of these follow the file structure used by Ashton-Tate's dBase II, III or 4 (later owned by Borland).

`read.dbf` is based on C code from <http://shapelib.maptools.org/> which implements the 'XBASE' specification. It can convert fields of type "L" (logical), "N" and "F" (numeric and float) and "D" (dates): all other field types are read as-is as character vectors. A numeric field is read as an R integer vector if it is encoded to have no decimals, otherwise as a numeric vector. However, if the numbers are too large to fit into an integer vector, it is changed to numeric. Note that is possible to read integers that cannot be represented exactly even as doubles: this sometimes occurs if IDs are incorrectly coded as numeric.

## Value

A data frame of data from the DBF file; note that the field names are adjusted to use in R using `make.names` (`unique=TRUE`).

There is an attribute "data\_type" giving the single-character dBase types for each field.

## Note

Not to be able to read a particular 'DBF' file is not a bug: this is a convenience function especially for shapefiles.

## Author(s)

Nicholas Lewin-Koh and Roger Bivand; shapelib by Frank Warmerdam

## References

<http://shapelib.maptools.org/>.

`write.dbf`

## Examples

```
x <- read.dbf(system.file("files/sids.dbf", package="foreign"))[1:]  
str(x)  
summary(x)
```

read.dta

*Read Stata Binary Files***Description**

Reads a file in Stata version 5–12 binary format into a data frame.

Frozen: will not support Stata formats after 12.

**Usage**

```
read.dta(file, convert.dates = TRUE, convert.factors = TRUE,
         missing.type = FALSE,
         convert.underscore = FALSE, warn.missing.labels = TRUE)
```

**Arguments**

`file` a filename or URL as a character string.

`convert.dates` Convert Stata dates to Date class, and date-times to POSIXct class?

`convert.factors` Use Stata value labels to create factors? (Version 6.0 or later).

`missing.type` For version 8 or later, store information about different types of missing data?

`convert.underscore` Convert "\_" in Stata variable names to "." in R names?

`warn.missing.labels` Warn if a variable is specified with value labels and those value labels are not present in the file.

**Details**

If the filename appears to be a URL (of schemes 'http:', 'ftp:' or 'https:') the URL is first downloaded to a temporary file and then read. ('https:' is only supported on some platforms.)

The variables in the Stata data set become the columns of the data frame. Missing values are correctly handled. The data label, variable labels, timestamp, and variable/dataset characteristics are stored as attributes of the data frame.

By default Stata dates (%d and %td formats) are converted to R's Date class, and variables with Stata value labels are converted to factors. Ordinarily, `read.dta` will not convert a variable to a factor unless a label is present for every level. Use `convert.factors = NA` to override this. In any case the value label and format information is stored as attributes on the returned data frame. Stata's date formats are sketchily documented: if necessary use `convert.dates = FALSE` and examine the attributes to work out how to post-process the dates.
